# APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Inspector (with a good honours university degree in physics or biology, and teaching experience) of Schools (General) in the Ministry of Education for Northern Ireland—The Secretary, Civil Service Commission, Stormont, Belfast (February 19).

Lecturer in Agricultural Chemistry—The Secretary, Edinburgh and East of Scotland College of Agriculture, 13 George Square, Edinburgh (February 20).

Assistant Research Biologist—The Secretary and House Governor, Mount Vernon Hospital, Northwood, Middx (February 21).

Chief Chemist of the Coke Oven Installation at Nantgarw, near Cardiff—The Divisional Establishment Officer, National Coal Board, South-Western Division, Cambrian Buildings, Mount Stuart Square, Cardiff (February 21).

Assistant Lecturer or Demonstrator (with a good honours degree in chemistry or biochemistry) in Chemical Pathology—The Registrar, The University, Manchester 13 (February 28).

Assistant Lecturer or Lecturer in the Department of Electric Power Engineering—The Registrar, The University, Liverpool (February 28)

Deputy Chief Mechanization Engineer (Ref. TT/590), and Mechanization Engineers (2) (Ref. TT/591), in the Mechanization Branch of Production Department at London headquarters—The National Coal Board, Establishments (Personnel), Hobart House, Grosvenor Place, London, S.W.1, quoting the appropriate Ref. No. (February 28).

Lecturer (Grade III or II) in Experimental Physics—The Registrar, The University, Bristol (February 28).

Scientific or Senior Scientific Officer (Ref. G.35/53A) to assist in ante-mortem and post-mortem investigations on quality of meat, and a Senior Scientific Officer (Ref. G.36/53A) for investigation on general microbiology of foodstuffs, at the Low Temperature

Research Station, Cambridge—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting the appropriate Ref. No. (February 28).

Senior Lecturer in Pure Mathematics—The Registrar, The University, Sheffield (February 28).

Readership in Biochemistry at University College—The Academic Registrar, University of London, Senate House, London, W.C.1 (March 4).

Research Officer to the Division of Animal Health and Production, Sydney, to collaborate in the present programme of research in the mammalian skin and hair by means of tissue culture and grafting, together with histochemical, biochemical and biophysical methods—The Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2, quoting No. 4139 (March 7).

Scientific or Senior Scientific Officer (with a first- or second-class honours degree in chemistry, physics or chemical engineering) for research in physical, physico-chemical and biochemical problems on the preservation of fish, at the Food Investigation's new Humber Laboratory, Hull—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting F.32/53A (March 7).

Senior Research Worker to assist with the development of researches into family and community organization on Merseyside, and a Research Worker to assist with the development of researches in the industrial field on Merseyside—The Registrar, The University, Liverpool (March 7).

Chair of Physics at Queen Mary College—The Academic Registrar, University of London, Senate House, London, W.C.1 (March 9)

Deputy Director of Research—The Director of Research, British Leather Manufacturers Research Association, Milton Park, Egham, Surrey (March 9).

Lecturer in Engineering—The Registrar, University College, Cathays Park, Cardiff (March 14).

Lecturer in Psychological Medicine—The Secretary of University Court, The University, Glasgow (March 14).

Lecturer or Assistant Lecturer in Botany (with special interests in taxonomy and morphology) at University College, Ibadan, Nigeria—The Secretary, Inter-University Council for Higher Education in the Colonies, 1 Gordon Square, London, W.C.1 (March 14).

Scientists (with good honours degree or equivalent) in the Physics Department—The National Coal Board, Central Research Establishment, Stoke Orchard, Cheltenham, quoting TT/592 (March 14).

Senior Agricultural Economist (Farm Management Liaison Officer) and an Agricultural Economist, in the Provincial Agricultural Economics Service of the Department of Agricultural Economics—The Registrar, University College, Aberystwyth (March 14).

Nuffield Research Fellowships and Assistantships in the Department of Genetics for research on microbial genetics—The Secretary of University Court, The University, Glasgow (March 15).

Professor of Pharmacology—The Deputy Secretary, Royal College of Surgeons of England, Lincoln's Inn Fields, London, W.C.2 (March 16).

Regius Professor of Logic in the University of Aberdeen—The Private Secretary, St. Andrew's House, Edinburgh 1 (April 1).

Research Assistant to the Professor of Medical Chemistry in the John Curtin School of Medical Research—The Secretary, London Office of the Australian National University, 27 Russell Square, London, W.C.1 (April 30).

Assistant Lecturer in Physiology and Pharmacology—The Registrar, The University, Nottingham.

Electrical Engineers at a Ministry of Supply Research Establishment near Sevenoaks: (a) for development work on electrical components, (b) for trials of experimental equipment, (c) for development of electromechanical devices—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting D.20/53A.

Engineers in the Post and Telegraphs Department, Nigeria—The Director of Recruitment, Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1, quoting CDE.108/14/65.

Lecturer (Grade I) in Mechanical Engineering, and a Lecturer (Grade II) in Mechanical Engineering—The Registrar, The University, Nottingham.

Regional Trials Officer (with degree in botany or agriculture or equivalent qualification, and practical experience in crop production) for work possibly at Cambridge—The Secretary, National Institute of Agricultural Botany, Huntingdon Road, Cambridge.

Scientific Officers at Capenhurst: for molecular theory of gases and applied fluid dynamics (Ref. 411), and for aerodynamics of compressors and high-speed machinery development (Ref. 412)—The Ministry of Supply, Division of Atomic Energy (Production), Risley, Warrington, Lancs, quoting the appropriate Ref. No.

Senior Electrical Engineer in the Public Works Department, Sudan—The Sudan Agent in London, Sudan House, Cleveland Row, London, S.W.1, endorsed 'Senior Electrical/Engineer 1818'.

Senior Lecturer in Chemistry (with qualifications and experience in organic chemistry) at Bradford Technical College—The Director of Education, Town Hall, Bradford.

# REPORTS and other PUBLICATIONS

(*not included in the monthly Books Supplement*)

## Great Britain and Ireland

British Engine Boiler and Electrical Insurance Co., Ltd. Technical Report, New Series, Vol. 1. Pp. 212. (Manchester: British Engine Boiler and Electrical Insurance Co., Ltd., 1952.) 12s. 6d. [112

City and Guilds of London Institute. Report of the Council for the Year 1951. Pp. 64. (London: City and Guilds of London Institute, 1952.) [112

Proceedings of the BTH Second Summer School in Electrical Engineering. Pp. 212. (Rugby: British Thomson-Houston Co., Ltd., 1952.) [112

Ministry of Supply. Radioisotope Techniques: Proceedings of the Isotope Techniques Conference, Oxford, July 1951, sponsored by the Atomic Energy Research Establishment. Vol. 2: Industrial and Allied Research Applications. Pp. iv+177+33 plates. (London: H.M. Stationery Office, 1952.) 25s. net. [112

## Other Countries

Pontificia Academia Scientiarum. Scripta Varia 10: Studio fisico dell'aorta normale e patologica. Per Vittorio Del Borgo. Pp. iv+106. (Vatican City: Pontificia Academia, 1952.) [2611

Proceedings of the United States National Museum. Vol. 102, No. 3291: Contributions to the Morphology and Taxonomy of the Branchiopoda Notostraca, with special reference to the North American Species. By Folke Linder. Pp. 69+7 plates. Vol. 102, No. 3293: Some Marine Asellote Isopods from Northern California, with Descriptions of Nine New Species. By Robert J. Menzies. Pp. 117–159. Vol. 102, No. 3297: A New Crayfish from Alabama, with Notes on *Procambarus lecontei* (Hagen). By Horton H. Hobbs, Jr. Pp. 209–219. Vol. 102, No. 3299: A New Species of Commensal Amphipod from a Spiny Lobster. By Clarence R. Shoemaker. Pp. 231–234. # THE PRINCIPLE OF QUINQUENNIAL GRANTS

IN recent years there have been comments from both interested and disinterested sources on the success with which the University Grants Committee has carried out its task of allocating Government funds to British universities. It is a task which has required much knowledge and care, though it may be open to question whether this is realized by those advocating the application of a similar device in other fields of activity depending on Government support. However that may be, it is worth while examining some of the suggestions which have been made for new bodies on the lines of the University Grants Committee.

The fields suggested are varied, but they have one feature in common : they all require as a condition of efficient working that there should be a longer period than the calendar year for the review of their projects or activities. The last annual report of the Advisory Council for Scientific and Industrial Research, for example, was concerned at the adverse effect on the work of the Department of Scientific and Industrial Research of sudden or unexpected limitations in the Department's budget, and the absence of reasonably firm budgetary expectations for several years ahead. The Council's plea that the Department should at least be given the flexibility which the right to carry over unspent money from year to year would confer, found strong support in a subsequent debate in the House of Lords last June.

A like difficulty has been encountered by the British Institute of Management, which has also pointed out the impossibility of arranging for the efficient conduct of research on a year-to-year basis with no budgetary certainty. The British Council, in quite another field, has encountered the same difficulty, and the Government's handling of the question of overseas information services on a year-to-year basis has already called forth some well-deserved criticism. Nor will it have escaped notice that the Tweedsmuir Committee, in presenting its proposals for the reorganization of the Imperial Institute, recommended that the system of grant should be placed on a quinquennial basis. The success of the scheme which it advocates would, it is urged, "be prejudiced from the beginning if those in charge of it only know from year to year what money they can count on from official sources, and are limited to budgeting expenditure on a rigid annual basis". More specifically than the other bodies already mentioned, the Tweedsmuir Committee mentioned the University Grants Committee, and its comment is worth quoting : "It is the common experience of organizations responsible for educational and cultural relations that their programmes are liable to be seriously affected, and at times actually frustrated, if they are tied to annual budgets, so far as Government subventions are concerned. We need do no more here than quote the example of the University Grants Committee, which owes its admittedly successful operations over a number of years to the fact that it has been able to plan its grants to Universities on the basis of quinquennial programmes. We strongly urge that the new Institute be treated on a similar basis, both in regard to recurrent and non-recurrent expenditure".

What is here contended is that the administration of Government funds should be effected by methods appropriate to the purpose of that expenditure, and not by methods determined primarily by financial convenience. The argument is not invalidated because public ignorance of the Imperial Institute, to which the Tweedsmuir report testifies, would militate very considerably against the success of the device in that instance. As part of a general scheme for securing the wise and efficient expenditure of public money on educational and cultural purposes, the new Institute might well be included. If some such device cannot be found, the Tweedsmuir Committee gives clear warning that it would be wiser to abandon pretence and accept the humiliation of closing the Institute and putting the premises to other use.

Some very clear thinking will obviously be required before any such scheme of quinquennial budgeting and accounting could be formulated. The device, or rather its extension, is likely to be opposed by the Treasury on traditional grounds. Such opposition should be overcome by demonstrating the wastefulness and inefficiency of the annual system; and accordingly every care should be taken that no claims are advanced which cannot be fully substantiated as being in the public interest on that ground alone.

Nor is reception by the Government likely to be favourable, if only for the reason that some further slice of public expenditure is removed from immediate control and that an incoming Government will be bound, possibly for several years, by the allocations of its predecessor. That case, however, is equally answerable. It should be emphasized that the object is, not the elimination of control, but the exercise of control where it will be most effective and ensure that expenditure already incurred is not wasted by short-sighted action. Nor, where scientific or technical research is concerned, should there be any hesitation in pointing out to-day the fallacy of imagining that under present conditions any efficient economy in national expenditure can be achieved without touching the categories in which it is now mainly incurred.

That brings us back once more to the question of public understanding and appreciation of what is involved, and public discussion must proceed while the exact means for providing the appropriate control are elaborated. Research is obviously one broad category to be covered, and the trend of questions in recent months in the House of Commons regarding expenditure on the Department of Scientific and Industrial Research, with the Government's abandonment of even the planning of a Science Centre, have increased the misgivings which were brought to a head by the Advisory Council's report. Much fundamental research is already safeguarded through the grants made under the University Grants Committee; but these amount to a small fraction only of the national expenditure on scientific and industrial research. Whether under the Lord President of the Council the functions of the Advisory Council on Scientific Policy could be developed to provide the appropriate safeguards for Parliamentary grants for scientific and industrial research in general might at least be worth examining.

The position of the social sciences and of bodies like the British Institute of Management requires further consideration. It is conceivable that a 'Social Grants Committee' might meet the situation; but there are obvious difficulties and objections. On the research side it might overlap the functions of the University Grants Committee, unless university institutions were clearly excluded. Even with such exclusion, the Committee could scarcely frame its grants without full knowledge of the social research at university institutions, and there is at present no social science research council which could assist. Furthermore, while it might be simple for such a body to cover the new Imperial Institute, the activities of the British Council are another question, particularly in view of the relation of its overseas activities to those of other, including Government, bodies now being considered by the Overseas Information Services Committee.

Here it may be observed that while the Clapham Committee on the Provision for Social and Economic Research, reporting in July 1946, rejected as premature the proposal for a Social and Economic Council on the lines of the Medical Research Council or the Advisory Council for Scientific and Industrial Research, it recommended consideration of the establishment, under the University Grants Committee, of a sub-committee to advise on matters relating to the social sciences. The Committee was clearly alive to the importance of continuity in such research, and the need for financial arrangements other than on an annual basis has been endorsed by subsequent experience as well as by the practice of the Nuffield Foundation and the United Kingdom Carnegie Trust in making their grants. Something wider is, however, required; though it requires consideration whether it is possible for all such grants for social and cultural purposes to be administered through one body, or whether some other arrangement, for example, under the Lord President of the Council or a sub-committee of the Advisory Council on Scientific Policy, would be wiser.

From the point of view of recruiting and retaining staff for overseas information work, long-term planning is essential. In any event, the need for co-ordinating the activities in this field of the British Council, the external services of the British Broadcasting Corporation and the work of the Central Office of Information, leads to a similar conclusion. It may be recalled, moreover, that the Select Committee on Estimates itself, in its ninth report for the session 1951–52, recommended, as a result of its inquiry into overseas broadcasting, a system of quinquennial grants for the overseas services of the B.B.C., in order to enable the Corporation to plan ahead for reasonable periods in providing what is essentially a long-term project.

As has been observed earlier (see *Nature*, 170, 634; 1952), the administration of such grants and the continuing scrutiny of the appropriateness of particular services to changing conditions may well involve the establishment of an independent body on the lines of the University Grants Committee. On practical grounds there will be objections to multiplying such bodies, and some hard thinking will be necessary to determine the minimum which will serve the objective, without either overlapping or failing to provide support and continuity where they are required in the national interest. Provided, however, these objectives are clearly defined, the task is not insuperable, and the attempt to discharge it could promote that clearer mutual understanding between the scientific man and administrator, using these terms in their widest sense, which is an essential condition for the functioning of devices of this type.

The recent memoranda published by the U.S. Commission on Financing Higher Education (see *Nature* of February 14, p. 273) are a most welcome contribution to the clear thinking that is essential to secure the smooth functioning of the University Grants Committee system in future, still more its extension into other fields. First there must be a large measure of public understanding of what is required, of the importance of the method of control or accounting being adjusted, not primarily to administrative or budgetary convenience, but to the purpose to be served—scientific, technical, cultural or educational. Without that understanding, adoption of such a system is unlikely for long to provide bodies such as the British Council, the British Institute of Management, the Imperial Institute or even the British Broadcasting Corporation, which are ill-equipped with defences such as the universities still enjoy against infringements of their autonomy, with the necessary safeguards for continuity of their research and like activities. That task of education should be the first to be tackled. It extends somewhat beyond the field over which the Parliamentary and Scientific Committee is normally active; nevertheless, the Committee could play an important part so far as science is concerned, whether we are concerned with the physical sciences or the social sciences. The Committee already enjoys a large measure of goodwill which should make it considerably easier to promote a clearer understanding between the administrator—Minister or Civil servant, member of Parliament—and the scientist or technologist. What is important is that no exasperation over the mistakes or follies of the past should be allowed to impede the co-operation in this task of public education of all who understand what is involved, whatever their primary interest may be. The extension of any such device must be advocated solely on the grounds of national interest—whether economic, social, technical or scientific—and of its appropriateness to the purpose to be served; its adoption for any particular purpose or field must be supported by a resolute and sustained effort to secure the sympathy and understanding of all affected, no matter how unfortunately the situation may have been prejudiced in the past.

# ADOLF VON BAEYER: CHEMIST AND MAN

## Adolf von Baeyer, 1835–1917

Von Karl Schmorl. (Grosse Naturforscher, Band 10.) Pp. ix+214. (Stuttgart: Wissenschaftliche Verlagsgesellschaft m.b.H., 1952.) 12.50 D. marks.

ADOLF VON BAEYER was born in 1835 and died in 1917. His astonishingly long period as an active worker in chemistry extended from the early days of the classical theory of organic molecular structure until the coming of sub-atomic chemistry: his first research paper was published in 1857 and his last in 1915, at the age of eighty. Soon after Bunsen had succeeded Gmelin at Heidelberg in 1852, the young Adolf Baeyer went to his laboratory from Berlin as a *Doktorand*. Being attracted to organic chemistry, Baeyer soon attached himself to Kekulé, then a little-known ***Privatdozent*** at Heidelberg. Baeyer's work with Kekulé, on arsenic methyl chloride, brought him the Berlin doctorate in 1858, a historic year that witnessed the publication of Kekulé's fundamental theory of organic molecular structure.

From the Gewerbe-Institut at Berlin, Baeyer migrated to the Strassburg chair in 1872, and three years later he succeeded Liebig at Munich. It was at Munich, with the aid of a galaxy of collaborators whose names were later to become household words in chemistry, that Baeyer carried out the long and varied series of researches which entitled him to be regarded as the founder of modern structural organic chemistry. One of his most famous pupils, W. H. Perkin, jun., to whom Baeyer became "the object of a lifelong intellectual devotion", selected his researches on indigo and its derivatives as "among the most brilliant in the whole range of organic analysis and synthesis", and characterized his "schwere, scheussliche und gefährliche" researches on the reduction of the phthalic acids as "so masterly in all their details that they must always remain as a monument to Baeyer's experimental skill and theoretical ability".

The book under review, which is the first comprehensive biography of Baeyer to be published, gives a concise and documented review of his contributions to organic chemistry; but it is chiefly remarkable for a good deal of new material, including some interesting illustrations, relating to Baeyer's ancestry, family circumstances and personality. In 1932, Prof. Hans Rupe, of Basle, published some charmingly written reminiscences of life in Baeyer's laboratory in the early 'nineties of the past century (*Nature*, 131, 294; 1933). This and other sources have been drawn upon by the present biographer in building up an edifying picture of the personality of this great chemist. In these references the celebrated 'Bleikammer', or 'lead chamber', naturally looms largely; such was the name given to the room in which Baeyer submitted students of pharmacy and medicine to oral examinations, which included, at one time, exhaustive questions on the lead-chamber process for making sulphuric acid.

Baeyer had certain unorthodox characteristics as an examiner, such as turning his back upon the candidate, giving him abruptly a time limit for each question, and tapping impatiently with his pencil while the unhappy victim was considering what to say. "What do you see having a red colour when you go into a pharmacist's shop? You have two minutes in which to answer." On such occasions Baeyer was apt to formulate questions designed (in his opinion) to make the candidate think, rather than to reproduce book knowledge. One can imagine the *Examensangst* (expressive word !) of an aspiring pharmacist when asked suddenly : "What happens when a red cyclist collides in the street with a Munich tramcar ? You have three minutes in which to answer". When the second-hand of the examiner's watch reached the prescribed mark without the astonished candidate having referred to the effect of bringing together the primary red and blue colours, Baeyer would admonish him : "Sie müssen denken lernen !" Naturally, there was another side to all this, and at intervals unofficial collections of Baeyer's questions were issued in the form of a 'swot book', or, to give it a more dignified name, an *Examensfragenheftchen* ; and Baeyer found it increasingly difficult to hit upon new questions.

Altogether, this is an informative and entertaining book, deserving of a wide welcome from chemists and others.

JOHN READ

## PSYCHIC REMINISCENCES

### Telepathy and Spiritualism

Personal Experiments, Experiences and Views. By Dr. J. Hettinger. Pp. 150. (London : Rider and Co., 1952.) 16*s*. net.

### Psychic Oddities

Fantastic and Bizarre Events in the Life of a Psychical Researcher. By Hereward Carrington. Pp. 183. (London : Rider and Co., 1952.) 16*s*. net.

IN these two books by, respectively, Dr. J. Hettinger and Mr. H. Carrington, the authors summarize some of their experiments and conclusions in psychical research.

The first is an account of Dr. Hettinger's personal attempts to arrive at the truth regarding telepathy and spiritualism. In the course of his discussion he provides abstracts of some of his previously published works, including his two books, "The Ultra-Perceptive Faculty" and "Exploring the Ultra-Perceptive Faculty", which deal with his investigation of the alleged faculty of certain persons whereby paranormal knowledge is gained about a person or thing through the use of some object acting as a key or pointer. From the simpler type of experiment, Dr. Hettinger proceeded to an interesting and ingenious "pictorial method" in which he attempted to show that the transmission of the content of illustrated matter could be conveyed to a percipient. with results so far in advance of what might be expected by chance or other normal factor that a paranormal explanation had to be invoked.

Before dealing with his own experiments, Dr. Hettinger briefly discusses those of some of his contemporaries, including Dr. S. G. Soal, Mrs. M. Goldney, Mr. Whately Carington and Dr. J. B. Rhine. With regard to many of these experiments, he is of the opinion that they do not, as is often claimed, test the existence of any psychic faculty through statistical evaluation or ascertain the functioning of such a faculty as regards past, present and future.

Although Dr. Hettinger is convinced of the validity of his own findings and their value as pointing the way to various further possibilities, he does not appear to have dealt seriously with the published criticisms of his experiments in relation to the chance factor, bias in the assessment of the results, and inadequacy of the control material. Although, at first sight, it would appear that many of his results are clearly due to the operation of some unknown factor, this feeling is much weakened by a careful scrutiny of the conditions and by the omission in the printed accounts of details clearly necessary to any fair appraisal of the facts. Although the book has both an index and a bibliography, only two items in the latter are dated, and only two give the place of publication, omissions which, in a work of this kind, are difficult to excuse.

In his "Psychic Oddities", Mr. Hereward Carrington, the veteran American psychical researcher, has put together a number of his personal reminiscences coupled with a selected number of odd experiences recorded by others. Unlike Dr. Hettinger, he has made but a few lengthy series of experiments himself, and in this volume he is content to give the reader a lively sketch of mediums, research workers and magicians he has known, interspersed with many amusing anecdotes. Unfortunately, Mr. Carrington has failed to provide adequate documentation for the stories he tells, and thus the reader is debarred from following up the material, tracing it to its source and then judging whether there is any case to answer.

E. J. DINGWALL

## DUNS, SPINNERS AND SEDGES

### An Angler's Entomology

By J. R. Harris. (New Naturalist Series.) Pp. xv+268+48 plates. (London and Glasgow : Wm. Collins, Sons and Co., Ltd., 1952.) 25*s*. net.

TO the entomologist the fly-fisher's nomenclature is baffling. His almost mystic faith in some particular artificial fly, on a particular stretch of water, on a particular evening is impressive, especially when he is successful ; and yet, somehow, it savours far more of chance than of sound intention.

Mr. J. R. Harris takes us right into the heart of these arcana, not as an iconoclast debunking the whole mystery but as an angler and entomologist who, more successfully than his predecessors, has tried to make sense of it. His is the right approach for the fisherman, because it starts from what he knows and has experienced—from his 'known' to his 'unknown'. This book is not a treatise on aquatic entomology : it is what it purports to be, an angler's entomology dealing with the questions the intelligent angler asks and the information he seeks. Without obtruding systematic entomology, it brings the work of Kimmins and Hynes—to mention only two systematists—to the assistance of the fisherman in unravelling the almost bewildering assortment of names given by his forbears to the flies he uses and the insects he sees.

It deals first with the Ephemeroptera or mayflies (duns and spinners), describing without too much detail their life-histories and habits, their enemies and their place in classification. Then follows a similar but shorter account of the Trichoptera or caddis-flies (sedges), the Perlidæ or stone-flies and a few Diptera like *Bibio* and the Chironomids. All this is straightforward, sound entomology. Next in the final third of the book come chapters on "Period Flies and Fish", on the taste and sight of fish, on those flies which are more attractive to fish and on fly dressing. There are four appendixes giving a list of angler's insects, keys to duns and spinners, descriptions of Ephemeroptera and hints on fly dressing.

The book is handsomely illustrated: one illustration in particular, of a stretch of water on the River Teith, gave me a sharp fit of nostalgia. Distribution maps and a good bibliography complete the angler's fare.

The special interest of this book lies in its combination of fisherman's lore and entomological science, in which neither is allowed for too long to dominate the other. Some of the author's comments are shrewd and worth noting, such as that while dichotomous keys afford the best scientific means of identifying an insect, really the best way is to be so familiar with the insect as to know it by sight, a method employed long after the diagnostic characters of the key have been forgotten. How true we know that to be. Then it is interesting to note that it may be more easy to identify an insect not from a dead specimen but from its effigy. Here again, long experience and intuition, only to be passed on in practice, can remind the man of science that his vocabulary is still too limited or his observation subconsciously too acute to allow him to record and describe all.

To me the best thing about this book is that the author never suggests that angling may become a science. To him, as to all true anglers, it is an art, and it would indeed be a bad day for us if all the rods on the river were equally lucky because everyone knew which ephemerid to put on. There are two questions one would like to ask the author: Why are the *Caenis* species called the "Angler's curse" and what has happened to "Jock Scott"?

J. W. Munro

# REFERENCE BOOK OF INTERFEROMETERS

## Modern Interferometers

By C. Candler. Pp. 502. (London: Hilger and Watts, Ltd., 1951.) 57*s.* 6*d.* net.

For many years Ewart Williams's "Applications of Interferometry" has been a standard British reference for physicists: the fact that a hundred-page monograph should occupy such a position for so long is evidence of the need for a more comprehensive work on interferometry. C. Candler's book goes far to satisfy this need. Whereas Williams treats the subject from a theoretical point of view and describes interferometers as examples of a particular class, Candler generally discusses a whole range of instruments in a more-or-less arbitrary order. For this reason the book is somewhat discontinuous, but is very suitable for the practical scientist who wishes to learn something about an instrument he has to use. Two-thirds of the book are devoted to interferometers, and the remainder to diffraction gratings.

The first chapter outlines the proposed arrangement of the material adopted. Instruments are to be grouped according to their functions: the measurement of difference in optical path, of length, of wave-length and of refractive index, and the analysis of hyperfine structure. This system is barely recognizable in the ensuing chapters, however. Chapter 2 deals with suitable light sources and factors affecting the widths of spectral lines, while Chapter 3 discusses the fundamental standards of length, although descriptions of the determination of the length of the metre in terms of light wave-lengths are deferred to Chapters 5 and 19.

Chapter 4 deals with interference effects in thick plates and thin films, and includes accounts of non-reflecting films, interference filters and surface finish; in connexion with the last, it is misleading to suggest that the technique adopted by Timms is very similar to that employed by Tolansky, as in only one of these is multiple-beam interference utilized. The next three chapters describe the principle and application of the Michelson interferometer and its derivative due to Twyman and Green. Bates's wave-shearing interferometer receives only two pages, with the Mach–Zehnder interferometer mentioned only (a diagram of one version of this instrument is also included at the end of the book). An account of the latter applied to the examination of fluid flow, as in wind tunnels, would have been a useful addition.

Interferometers used in the measurement of length and angle gauges are described in Chapter 8. The inclusion of an optical measuring machine and an optical comparator, neither employing interference, appears irrelevant. In Fig. 8.3 (p. 195) the author states that the prism has been drawn oversize "to avoid violating the laws of optics": a more serious violation is the inclusion of an eyepiece in the diagram, as with this arrangement the observer merely views an image of the pinhole. The eye is, of course, placed in the plane of the pinhole; a telescope of low power can both transfer this to a more convenient position and slightly magnify the gauges under examination.

Chapter 9 describes the Fabry–Pérot étalon and its use in the determination of the metre, while the next chapter deals with the stellar interferometer. Reflexion and transmission échelons are considered in some detail in two further chapters. An an illustration of the rather discontinuous treatment, Chapter 13 returns to the Fabry–Pérot étalon, dealing with its application to the measurement of wave-length and to the analysis of hyperfine structure. A chapter is allocated to the Lummer–Gehrke plate: the statement that this interferometer employs a process combining diffraction with refraction should surely read—reflexion with refraction. Four chapters on diffraction gratings follow, covering plane and concave gratings, their ruling, properties and methods of mounting. A short account of grating replicas is included; but no mention is made of developments during the past few years. Three short, concluding chapters describe the Fabry–Pérot étalon as a refractometer, and the Rayleigh and Jamin refractometers.

Numerous references are listed at the end of each chapter, with additional ones given in an appendix. The book already covers an enormous field, but, from the point of view of completeness, micro-interferometers might well have been included; the only reference is two paragraphs on the interference microscope. Space could have been found by the omission of irrelevant material, such as the examples quoted. Diagrams and script are clear, and the style is very readable. Because of the distribution of material, however, it is more suited as a book for reference than for general reading.

K. J. Habell

# BASES OF MICRO-CLIMATOLOGY*

By SIR DAVID BRUNT, F.R.S.

THE most fundamental factor which has to be taken into account in micro-climatology is the incoming solar radiation by day, and the long-wave radiation and absorption by the atmosphere and the surface of the ground. Over bare soil the absorption and emission of radiation by the earth are both brought about by a very thin layer of soil. When the soil has a covering of vegetation, the effective locus of both absorption and radiation may be situated at any level between the solid surface of the ground and the top of the vegetation, and this locus may be a layer the depth of which will depend on the character of the vegetation.

The main factors which control the change of temperature of the surface and of the air in contact with it, as a result of the transfer of heat by radiation and absorption, are the nature of the soil, soil drainage, vegetation, contour of the ground, aspect of the ground and nearness to large sheets of water.

## Climatology of Bare Soil

The climatology of bare soil is relatively simple. When the surface of the ground is heated by the absorption of incoming solar radiation by day, or cooled by the loss of heat by long-wave radiation by night, the gain or loss of heat at the surface is in part compensated by conduction to or from lower layers. It can be shown that in given meteorological conditions, or in other words, for a given rate of gain or loss of heat from the surface, the rate of change of surface temperature is proportional to $1/\sqrt{ks}$, where $k$ is the coefficient of thermal conductivity of the soil, and $s$ is its heat capacity[1]. Since soil is an aggregation of solid particles with the spaces between them filled with air or water, both the conductivity and the heat capacity will depend upon the extent to which these spaces are filled with air or with water. Since both the conductivity and heat capacity of air are very small, it follows that for a soil containing much air $1/\sqrt{ks}$ will be great, and surface temperature will vary rapidly when there is a net gain or loss of heat at the surface. Thus a sandy soil will have a large diurnal variation of surface temperature, and this is well exemplified by a comparison of meteorological observations at South Farnborough, on a sandy soil, with simultaneous observations at Croydon, on a chalky soil. The observations were taken during March 28–29, 1933, during a short spell of clear weather. (The Rickmansworth observations will be referred to later.)

Table 1

| | Max. March 28 | Min. March 29 | Range |
|---|---|---|---|
| Croydon | 65° F. | 35° F. | 30° F. |
| South Farnborough | 69 | 30 | 39 |
| Rickmansworth | 66·9 | 21·4 | 45·5 |

Thus the lighter the soil the warmer will be the clear afternoons and the colder the clear nights.

When the air within the soil is partially replaced by water, which has a higher conductivity and heat capacity, the variability of temperature is diminished. The fact that the fall of temperature from sunset to sunrise is much greater in summer than in winter, in spite of the fact that the time-interval from sunset to sunrise is much longer in winter than in summer, is due to the higher water content of the soil in winter. Water-logged soil has a lower diurnal variation of temperature than dry soil, or well-drained soil; but on undrained soil the evaporation of water from its surface maintains the surface temperature at a lower level by day and by night than on the same soil when well drained.

Soils may be arranged in the following order of decreasing diurnal variation of surface temperature: sandy soil, light loam, chalky soil, heavy loam and clay.

On clear nights the surface temperature of snow falls well below that of bare soil, since snow is about nine-tenths air. But, underneath a layer of snow only a few inches deep, the ground temperature has been observed to remain steadily at 0° C., while the upper surface of the snow varied from − 15° to − 4·6° C.

## Effect of Vegetation

The air above grass is colder by night and warmer by day than air above a bare surface. This is the joint effect of the trapping of air between the grasses, and of the poor conductivity of the soil-layers in which the roots are embedded. The first cause is more effective among tall than among short grasses, while the second may have very great effect where the grass root systems form a mat of horizontally running stems below the surface of the soil, such as one finds on the Romney Marshes. Evaporation from the surface of the grass leaves must also contribute to the lower night temperature.

A. Ångström[2] found that, in a field of grass 1 m. high, the incoming solar radiation was 1·08 cal. $cm.^{-2}$ above the grass, decreasing to 1·04, 0·28 and 0·19 cal. $cm.^{-2}$ at 0·5, 0·1 and 0 m., respectively, above the ground surface. The highest afternoon temperature and the lowest night temperature might thus be expected to be about 10–20 cm. above the ground, where the grasses are dense enough to absorb most of the radiation downwards. The same layer should be the effective outward radiating surface at night, and so the level of lowest temperature.

Similar results were derived by R. Geiger[3] in a field of winter rye. When the rye was short, radiation passed readily down to the ground; but after its height had grown beyond 0·5 m., the lower leaves showed rapid growth and formed the effective absorbing and radiating layer. The highest temperature by day and the lowest temperature by night were to be found at the highest level at which the lower leaves formed an effective obstacle to the downward passage of solar radiation by day and the upward passage of long-wave radiation by night. As the crop ripens the lower leaves wither, and the height at which the day and night extremes of temperature occur decreases but does not fall to zero. Cornfields surrounded by meadows are found on sunny afternoons to be sources of strong convection currents, in which a sail-plane can soar readily.

Within a bed of antirrhinums, at an early stage of growth the horizontal leaves offer a complete barrier to the passage of radiation in either direction. With well-developed plants the highest temperature during the afternoon is at about the level of the uppermost leaves, while the temperature falls off with distance from this level both upwards and downwards. Again, on a clear night the upper leaves form the effective outward radiating surface of the plants. The air cooled by the cold leaves can sink down to the ground, while partially mixing with the air below. The result is to yield the lowest air temperature at the ground, with an inversion of temperature up to levels above the uppermost leaves of the plants.

---

* Based on a lecture delivered at Wye College, Kent, on December 4.

In a forest with a thick canopy of leaves, the uppermost layer of the canopy is the effective absorbing and radiating layer. On a sunny day the ground below the trees, and the air immediately above it, remain cooler than the ground and the air above it in the open. On a clear night the air cooled by contact with the upper leaves of the canopy sinks to the ground, with the result that the air immediately above the ground is slightly colder than the air at the level of the canopy. In clear weather the air temperature at the ground is at all times lower than that of the air at the top of the canopy, and is lower by day and higher by night than the air temperature over open ground.

In a wood which has not a complete canopy of leaves, or among such plants as raspberry canes, some sunshine penetrates to the ground, and some is absorbed by the trunks of the trees. Day temperatures will then be intermediate between those in a forest with dense canopy and those in the open.

Some typical temperatures, observed by C. E. Cornford at East Peckham, Kent, on the morning of May 30, 1937, are given in the table below[4], these being minimum temperatures measured at 3 ft. above the ground.

Table 2

| | | | |
|---|---|---|---|
| Bare soil | 49·5° F. | Meadow close cropped | 45·7° F. |
| In wood | 49·0 | Meadow longer grass | 43·0 |
| Among raspberry canes | 48·2 | Grass and clover | 43·5 |

An unusual type of vegetation, judged by our experience of British trees, is the mallee scrub of Australia. The individual mallee tree has a number of trunks growing up from the same root, and its leaves hang downward vertically. The leaves thus help to check the horizontal movement of air, but allow radiation from the ground to pass outward freely, so that the temperature falls well below that over open ground. Any area covered with mallee scrub acts as a source of cold air.

## Effects of Contour

On a clear night the surface of the ground is cooled by radiation, and cools the air immediately above it. The cooling of the air is greatest over grass, especially over long grass. On sloping ground the cold air flows down the slope much as water would, yielding what are known as 'katabatic winds'. The cold air flowing downhill fills any hollow in the ground, and accumulates at the foot of the slope unless there is some ready exit which it can follow. The effect of accumulation in a valley-bottom of cold air from the slopes above is illustrated by the data in the last row of Table 1. The data refer to a station in a little sheltered valley which runs into the valley of the River Chess about halfway between Rickmansworth and Chorley Wood. At this station the diurnal range of temperature was 50 per cent higher than at Croydon. It is clear that neither a sheltered valley nor the lower reaches of an extensive grass-covered slope can offer an ideal location for either a home or an orchard. In some cases it is possible to deflect the current of cold air sideways by means of a diagonally running wall or thick hedge, or hessian screen, and so minimize the discomfort or damage such cold air can produce.

It was noted earlier in this article that over a snow surface the air can cool at night to temperatures far below those which would be found over bare or grassy ground similarly situated. Sloping snow-covered ground can therefore produce very strong katabatic winds, which can attain very high speeds down valleys which are fed with cold air from the sloping sides over extensive areas. Very strong katabatic winds are formed in this manner in valleys on the Antarctic continent.

## Effect of Aspect

B. A. Keen[5] states that on a slope facing south the soil temperature at 1½ in. below the surface may be as much as 15 deg. F. higher, with a correspondingly lower moisture content, than on a slope facing south. Aspect can thus have an important bearing on the local climate.

## Effects of Nearness to Large Sheets of Water

The diurnal variation of the surface temperature of deep water is small enough to be negligible by comparison with that of the ground, and places near large sheets of deep water will have a climate comparable with that of the seaside.

# BIOSYNTHESIS AND ENERGY TRANSPORT BY ENZYMIC REDUCTION OF 'ONIUM' SALTS

By Dr. D. W. WOOLLEY

**Rockefeller Institute for Medical Research, New York, N.Y.**

THERE has been such marked success in the understanding of the mechanism of simple enzymic syntheses, and of how energy is transferred in the course of carbohydrate metabolism, through use of the concept of an energy-rich phosphate bond such as that contained in adenosinetriphosphate, that among biochemists it is generally conceded that both the synthesis of a variety of chemical constituents of living matter, as well as the controlled transfer of energy in processes of life, probably occur through the functioning of 'active' or energy-rich phosphate esters and anhydrides. The purpose of this article is not to dispute this concept, because a vast amount of existing evidence makes it seem quite probable that carbohydrate fuel is burned, and the energy is captured for other vital functions by the intervention of such phosphorus compounds. Rather, it is my purpose to point out that living matter contains enzymes which bring about special types of syntheses, and that these reactions are not driven directly by the energy contained in phosphate compounds. In fact, phosphorus is not concerned in some of the biochemical syntheses. The energy which appears to drive these reactions seems to reside in quaternary ammonium ions or in sulphonium ions, and is liberated when these 'onium' compounds are reduced during the course of the reaction. In the case of the quaternary substances the reduction is from nitrogen of a valence of 5 to tertiary bases in which nitrogen has a valence of 3, while in the sulphonium compounds sulphur changes in valence from 4 to 2. The term 'valence' is used here because it simplifies the presentation. It denotes merely the number of bonds. However, the electronic transfers can be appreciated much more if one states that nitrogen in the quaternary ammonium compound acquires a pair of unshared electrons when it passes into the tertiary base. In the quaternary compound, this pair was shared with a carbon atom as a covalent bond. In other words, nitrogen in the tertiary base has acquired sole possession of the two electrons which, in the quaternary salt, it shared with carbon. Similarly, with the sulphonium compounds, the changes in shared electrons are not emphasized by the use of the term 'valence'.

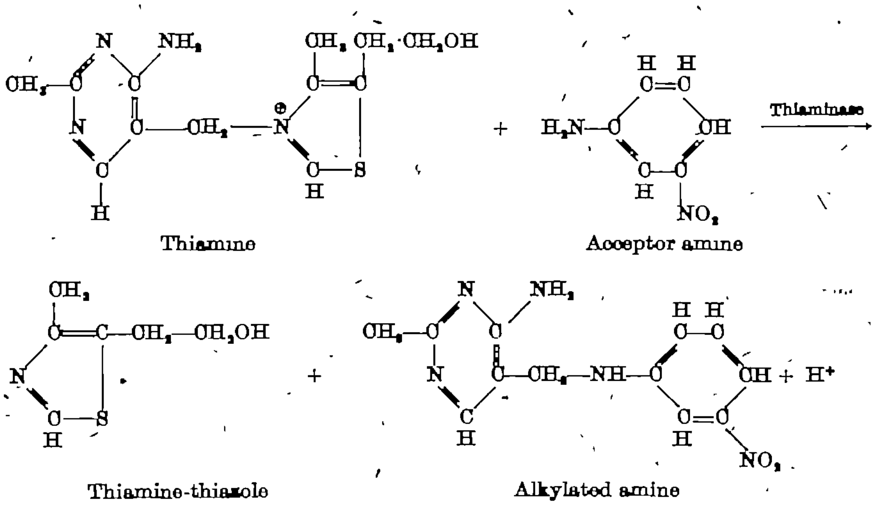
It seems probable, as will be discussed below, that some peculiarly useful properties arise from reactions in which 'onium' compounds are reduced, and that living organisms may employ them partly for this reason. In any event, these enzymic syntheses through the reduction of 'onium' compounds constitute a new mechanism for the formation of special substances and for the transfer of energy in living organisms.

The views of the author on this subject have arisen from a study of the enzyme of carp which destroys thiamine (aneurine, vitamin $B_1$). Because of this, let us consider the action of this enzyme, and substantiate the argument with other examples which have arisen in recent years.

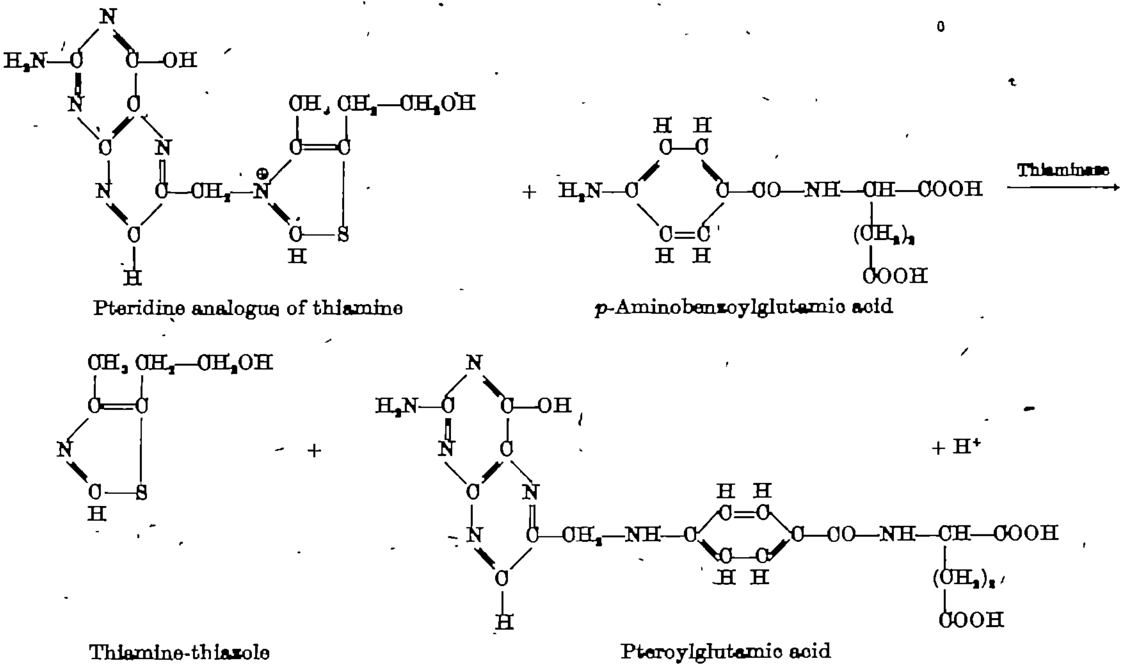
The existence of carp thiaminase, that is, an enzyme in carp which actively destroyed thiamine, was detected in 1941[1,2] after it had been noted that the feeding of ground raw fish to foxes called forth an epidemic disease which could be prevented or cured by injection of this vitamin[3]. The enzyme could be extracted from the fish by means of hypertonic salt solutions, and could thus be obtained free from cells. Subsequent investigations by many workers have revealed a similar enzyme to be present in such diverse living things as clams, several species of fresh-water fish, certain micro-organisms, and bracken ferns[4]. Somogyi[5] has also detected the ability of mammalian organs to destroy thiamine, although, in my experience, this ability of mammalian tissues, if it exists, is slight in comparison with that of carp and clams. Nevertheless, such thiamine-destroying enzymes seem to be widely distributed in diverse organisms.

The fact that carp extracts actually destroyed thiamine and did not merely sequester it was shown by the isolation of the products formed[6]. This demonstration, along with the heat lability and dependence on pH and temperature of the vitamin-destroying activity of the tissue[6], indicated that an enzyme was involved. This enzyme was called 'carp thiaminase'. It has been purified by ammonium-sulphate fractionation[7]. The products which it formed were the thiazole moiety of thiamine (that is, 4-methyl-5-hydroxyethylthiazole), and a conjugate which contained the pyrimidine portion of the vitamin. A secondary reaction proceeding in carp tissues was recognized. This led to the formation of the free pyrimidine moiety of thiamine, 2-methyl-4-amino-5-hydroxymethylpyrimidine, from the conjugate formed in the main reaction. Clearly, then, the enzyme attacked thiamine and liberated the thiamine-thiazole, and at the same time attached the pyrimidine half of the vitamin to something else. It is in this latter process—the attaching to something else—that the synthesizing action of the reaction becomes clear.

The nature of this 'something else' was made plain by the work of Sealock and Davis[8]. Earlier investigators[6] had found that the action of carp thiaminase was greatly reduced when solutions of it were dialysed. The dialysable component, which was stable to heat, was considered to be a coenzyme. However, there was a strange property of the reaction which had caused much wonder in the early investigations. This was that a given quantity of enzyme would destroy a definite amount of thiamine very rapidly; but when more substrate was present, no more was destroyed, even during prolonged incubation[6,7]. Sealock and Davis recognized that the enzyme had two substrates, both of which must be present for the reaction to proceed. One substrate was thiamine and the other was the dialysable component. However, the second substrate was not specific, because any one of a variety of amines could serve. Thus, in the work of Sealock and Davis, either *meta*-nitroaniline, or *meta*-aminobenzoic acid was effective. In clams, this second substrate appears, from the work of Barnhurst and Hennessy[9], to be probably the amino-acid taurine (positive identification has not yet been accomplished, but the evidence in Barnhurst and Hennessy's and subsequent papers strongly suggests that the situation is as stated). So long as both substrates, that is, thiamine and a suitable second component, were fed into the reaction system, the enzyme continued to function, and did not stop in the puzzling fashion just mentioned[7,8]. The very



Equation 1. Carp thiaminase reaction with *m*-nitroaniline as acceptor



Equation 1. Synthesis of pteroylglutamic acid by the action of carp thiaminase

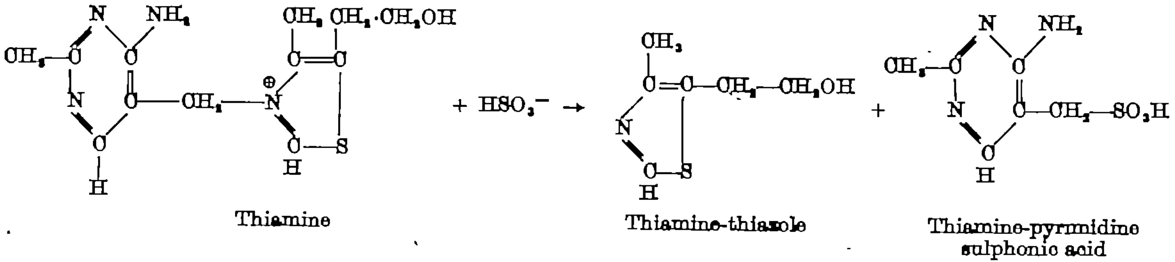
great activity of carp tissues in destroying thiamine can only be appreciated when the second substrate, which we may call the acceptor amine, is added. In fact, measurements of the quantity of thiaminase in tissues which were made prior to this discovery are of very questionable value. The true enzymic content can only be found when both substrates are present in excess.

The reaction catalysed by thiaminase can now be formulated in the manner shown in equation (1). The biochemical synthesis which this enzyme brings about thus becomes plain. It is the alkylation of the acceptor amine with the pyrimidine portion of the thiamine molecule. In the case of clam tissue studied by Barnhurst and Hennessy[9], the synthesis involves the alkylation of taurine (the acceptor amine) with this same alkyl group. The product is apparently what has been called 'icthiamine'[4]. Because several primary aromatic, and several aliphatic, amines can each be used readily by the enzyme as its second substrate, a variety of new substances can thus be formed. Some of these products have a complexity of structure which it is gratifying to find an enzyme can produce.

The synthesizing abilities of the enzyme became clear when it was possible to induce it to form a compound of widely-recognized biochemical importance, namely, pteroylglutamic acid[10]. The products formed from thiamine and acceptor amine are, as we have seen, thiamine-thiazole and alkylated acceptor amine. Pteroylglutamic acid may be viewed as an acceptor amine (p-aminobenzoylglutamic acid) which has been similarly alkylated. The only difference is that the alkyl group has been a pteridylmethyl rather than a pyrimidylmethyl. If, then, the proper pteridine analogue of thiamine were prepared in which the pteridine portion of pteroylglutamic acid replaced the thiamine pyrimidine, and if this quaternary salt were mixed with p-aminobenzoylglutamic acid and carp thiaminase, one could reasonably expect some pteroylglutamic acid to be formed (see equation 2). Actual experiment showed that some was, indeed, synthesized[10]. The reaction did not proceed as readily as was the case when thiamine, rather than its pteridine analogue, was one of the substrates. However, this may not be too surprising when the structural differences of the two analogous substrates are remembered. Although this synthesis of pteroylglutamic acid can thus be demonstrated *in vitro*, there is no reason for believing that the actual formation in living organisms follows this course. Rather, this seems to be an experimental model to illustrate the synthetical capabilities of this enzyme.

What is the source of the energy which brings about these syntheses? The reactions proceed with great speed in the absence of any dialysable phosphorus compounds. The true nature of the process can best be appreciated if one recalls a well-known, non-enzymic cleavage of thiamine. The vitamin reacts readily with bisulphite ions according to the scheme shown in equation (3). What is new about this reaction is to recognize that it is an oxidation-reduction. The sulphur in bisulphite is tetravalent, whereas that in the pyrimidine-sulphonic acid is hexavalent. Similarly, the quaternary nitrogen of thiamine is pentavalent, and the tertiary nitrogen of thiamine-thiazole is trivalent. In the reactions catalysed by carp thiaminase, a similar reduction of the quaternary nitrogen takes place. In both cases thiamine is the oxidizing agent, the quaternary nitrogen of which is reduced during the reactions. The author feels that this reduction of the thiamine nitrogen is the source of the energy.

Recently, a series of four papers has appeared in which the true nature of the thiaminase reaction is concluded to be that of base exchange[11]. Pyridine was found to react with thiamine in the presence of the enzyme to give a small yield of a substance in which the thiamine-thiazole was replaced by an unsubstituted pyridine ring with the thiamine-pyrimidylmethyl group attached to the pyridine nitrogen (see equation 4). This exchange of pyridine

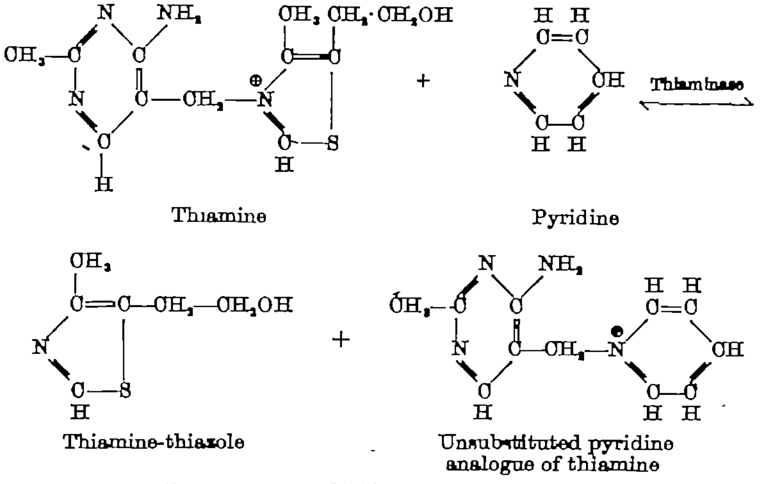


Equation 3. The well-known non-enzymic sulphite-cleavage of thiamine

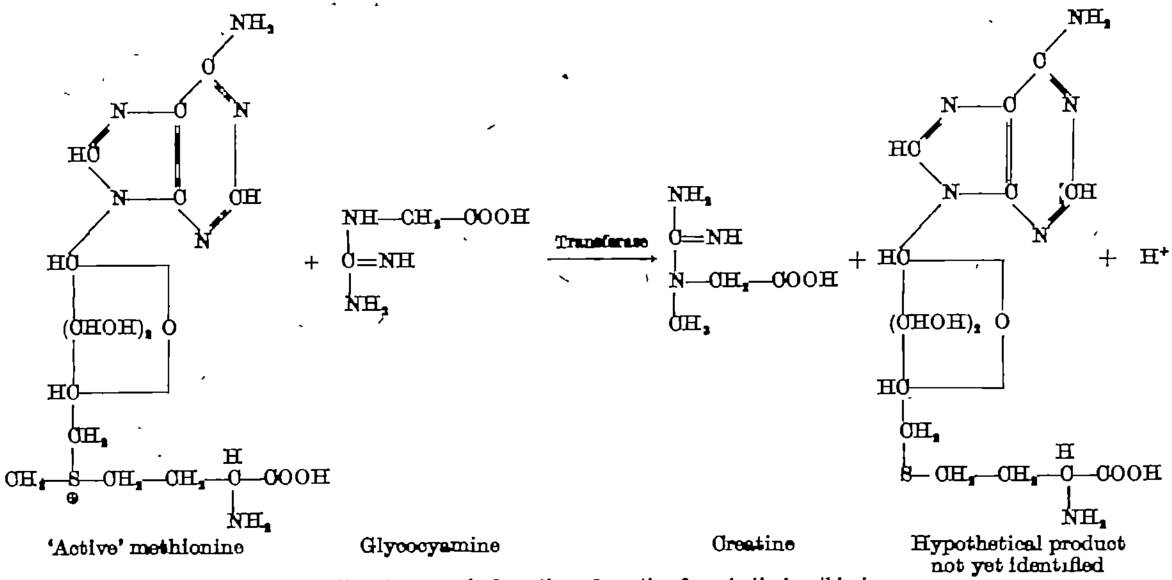
for thiamine-thiazole was found to be reversible in the presence of the thiaminase. The alkylation of primary amines in the manner in which we have been discussing was considered as just one more example of the base-exchange catalysed by thiaminase. To me, the emphasis on the base-exchange character of the reaction obscured the aspect of energy transport and ionic change (to be discussed presently), which are more important in the understanding of the real processes involved. The exchange of thiamine-thiazole for pyridine might easily be the result of a slightly lower energy-level of the unsubstituted pyridine analogue of thiamine when compared with the vitamin itself. The fact that this exchange was readily reversible by manipulation of the relative concentrations of the reactants and products might be in favour of such a view. On the other hand, I am not aware of any experiment in which thiaminase has been shown to reverse the alkylation of primary amines. Thus, when relative concentrations of the substances in equation (1) are manipulated, no one has yet been able to observe any synthesis of thiamine. The only way in which thiamine has yet been formed in such a situation is to utilize the energy of a glycolytic system. Thus, Barnhurst and Hennessy[9] have shown that although icthiamine (presumably taurine alkylated with the thiamine-pyrimidylmethyl group) plus thiamine-thiazole does not yield any thiamine in the presence of thiaminase, thiamine is formed when icthiamine and thiamine-thiazole are incubated with glycolysing yeast. In other words, the only way to reverse (or apparently to reverse) this reaction is to pour into the system a large amount of energy derived from the oxidation of glucose. In terms of the mechanical analogy to be discussed below, the quaternary storage battery must be recharged (that is, the nitrogen must be restored to the quaternary, pentavalent state) by the expenditure of the energy of glycolysis. Mere manipulation of concentrations of participants is not enough. In the case in which pyridine reversibly replaces thiamine-thiazole (as in equation 4), one still has a quaternary salt as the product, even though this pyridinium compound may perhaps be slightly less charged with energy than is thiamine itself. The difference in energy-level of the nitrogen in icthiamine or in the nitroaniline compound of equation (1), from that in the pyridinium salt, may well be of a different order of magnitude.

No exact calculations have yet been made of the change in free energy during the thiaminase reaction pictured in equation (1). This is partly because the position of equilibrium is very far to the right. The best approximations, from indirect measurements, have suggested a change in free energy of 7,000–8,000 Calories per mole. This value may require considerable revision in the light of future results.

Thiamine is by no means the only quaternary ammonium compound of recognized biochemical importance. One thinks also of cozymase (diphosphopyridine nucleotide), of triphosphopyridine nucleotide, of acetylcholine, of choline, and of carnitine, to mention only a few. Is there any evidence that enzymes exist which catalyse the reduction of such substances to tertiary bases in a manner similar to that pictured for the action of thiaminase on thiamine? Thus far only one (in addition to thiaminase) is known; but with the recognition of the basic phenomenon, a concerted search can be made which may uncover others. Up to the present time, progress has depended on chance discoveries. The other example is that of 'diphosphopyridine nucleotidase', or the enzyme which destroys diphosphopyridine nucleotide by cleavage at the quaternary link between ribose and nicotinamide. This enzyme was discovered by Mann and Quastel in mammalian brain and liver[11] and a similar enzyme has been found in other animal tissues. One such has been purified from the cultures of the fungus *Neurospora crassa*[12]. These enzymes attack the quaternary nitrogen in diphosphopyridine nucleotide, liberating nicotinamide, in which nitrogen has now a valence of 3. The other product is ribose-5 phosphate united in pyrophosphate linkage to muscle adenylic acid. This reaction differs markedly in at least one respect from that catalysed by thiaminase. With the diphosphopyridine nucleotidase, no acceptor amine is required; rather, water alone can be said to accept



Equation 4. Exchange of tertiary bases catalysed by thiaminase



Equation 5. Enzymic formation of creatine from 'active' methionine

the aldehydic end of the ribose phosphate portion of the molecule. With thiamine in the thiaminase process, there is no reaction without an acceptor more complex than water (that is, a suitable amine). It may well be that if a suitable acceptor for the diphosphopyridine nucleotidase could be found, the reaction would be greatly accelerated and the activity of the enzyme remarkably enhanced, just as was the case with thiaminase. If this were so, a rather complex molecule could be expected to form as the product, in which would be contained the ribosephosphate-adenylic portion of diphosphopyridine nucleotide.

The need to search for enzymes which act in this fashion on acetylcholine and other biologically important quaternary salts as one of their substrates seems self-evident.

Very recent disclosures have indicated that quaternary ammonium salts are not the only kind of 'onium' compounds which undergo the type of transformation just discussed. The work of Cantoni[14] on the nature of the so-called 'active' methionine has shown that sulphonium compounds exist in Nature and participate in certain important biochemical syntheses. The processes are so similar to those examined with the quaternary ammonium compounds that they warrant our attention. When either creatine or N-methylnicotinamide is synthesized in mammalian tissues, the methyl group which appears in these products arises from the terminal methyl group of methionine. However, methionine itself will not react. Rather, it must be activated by the intervention of adenosinetriphosphate and a special enzyme. When this special enzyme acts on adenosinetriphosphate plus methionine, 'active' methionine is formed. Cantoni was able to isolate this 'active' methionine, and showed, much to his surprise, that it did not contain phosphorus. (The old and established belief would have pictured the phosphorylation of methionine in order to activate it.) Rather, he showed that the 'active' methionine was a sulphonium salt in which adenosine had been added to the sulphur atom of methionine, thereby raising its valence to 4 as illustrated in equation (5).

This 'onium' salt is one of the substrates of the specific enzymes which transfer the methyl group. The second substrate is glycocyamine for the enzyme which synthesizes creatine; it is nicotinamide for the one which forms N-methylnicotinamide. (Because the product, N-methylnicotinamide, is itself a quaternary ammonium salt, it seems probable that the sulphonium compound is at a higher energy-level than the quaternary ammonium salts. The sulphonium compound, during reduction, can thus form a quaternary ammonium compound.) To me, the energy which drives these reactions has a source similar to that involved in the thiaminase reaction. It is the reduction of the sulphonium salt, in which sulphur has a valence of 4, to the divalent condition. In the course of this reaction, creatine or N-methylnicotinamide is synthesized. With such a mechanism in mind, the natural-occurrence in cabbage of a related sulphonium salt, namely, methioninemethylsulphonium chloride[15], has added interest.

We may well ask why Nature has troubled herself about this new mode of synthesis and energy transport. Why could she not have made do with the high-energy phosphate compounds alone? A mechanical analogy may help to clarify thinking about this question. Let us liken an organism to a motor-car. This rather elaborate mechanical contraption derives its energy from the controlled combustion of petrol, just as the living organism does by the combustion of carbohydrate. The modern motor-car has this major energy-yielding process rather well controlled. The coupling of the combustion to forms of useful work and to proper production of heat in desirable places has been neatly arranged. Nevertheless, for rather special purposes, for example, for lighting, it has been found much better to convert the energy into electrical forces, and to accumulate these in a storage battery for use when, and exactly when, required. Of course, one could still burn petrol in the headlights; but it is much better to have an electrical system. For ignition, this rather specialized form of energy is vital to the proper functioning of the main energy-yielding process. So also with living organisms, it may be found highly desirable, and possibly vitally important, to have other means of storing and utilizing energy. These oxidation-reduction reactions seem to be one of these specialized processes. The 'onium' compounds are the storage batteries in which this takes place. Just as in the motor-car, the recharging of these batteries is probably done by a reaction coupled to the main energy-yielding processes.

With this rather crude analogy in mind, let us examine two striking properties of the enzymic reduction of 'onium' salts which organisms may find useful. One is the ionic changes which result, and the other is the extraordinary speed of the reactions. When the quaternary ammonium compounds are converted into tertiary bases, or when sulphonium salts are similarly involved, one starts with a highly ionized but neutral salt, and ends with a weak tertiary base, which at physiological *p*H's is practically non-ionized. This fact arises from the strongly basic properties of quaternary ammonium bases, which are of the same order of basicity as is sodium hydroxide. Simultaneously with the obliteration of this ion, a hydrogen ion appears. The formation of acid, that is, a hydrogen ion, has, in fact, been used to measure both thiaminase[16] and diphosphopyridine nucleotidase[17]. Lorente[18] has recently remarked about similar ionic changes.

In the reduction of either thiamine or diphosphopyridine nucleotide, a relatively large organic ion disappears, and is replaced by a small hydrogen ion. Thus, not only is *p*H-control influenced, but also a more readily diffusible ion (the hydrogen ion) is suddenly formed.

The remarkable speed of the reduction of 'onium' salts warrants comment. Thus, the thiaminase of carp viscera will destroy all the added thiamine (provided the naturally occurring acceptor amines are in excess) in about five minutes[6,7]. The diphosphopyridine nucleotidase of brain is said to destroy an amount of cozymase equal to the dry weight of the brain in an hour[17]. While these great activities could be said to result from an extraordinarily large concentration of the respective enzymes in the tissues, the fractionations which have been carried out show that this is probably not the case. Hence we must conclude that the enzymes act with great speed.

In physiology, at least two processes are known to be associated both with remarkable speed and with the shift of ions. These are the propagation of nerve impulses and the contraction of muscles. Thus, the action potential is associated with, and may even be said to result from, the migration of potassium and sodium ions. The contraction of muscles depends on the migration of calcium and magnesium ions to the contractile substances[19]. One pictures these essential ionic changes as being caused by diffusion. However, recent work[20] has shown that diffusion based on osmotic differentials is much too slow to account for the observed speed of neural and muscular action. It is possible that the disappearance of the organic ion and the generation, on the spot, of the more readily diffusible hydrogen ion, might contribute to the real mechanism. The extraordinarily high speed of the reductions of 'onium' salts would be compatible with such an involvement. Furthermore, the prominent occurrence of 'onium' salts such as acetylcholine, thiamine, and diphosphopyridine nucleotide in nerves, and of carnitine in muscles is suggestive. Creatine, the role of which in muscular contraction has long been ascribed to creatine phosphate, might assume a second role, because, as we have seen, it is synthesized in muscle by an enzyme which acts on the 'active' methionine, a sulphonium salt, with concomitant ionic changes.

There is no real proof that these enzymic processes have anything to do with nerve transmission or muscular contraction. Even if the reduction of 'onium' salts should be found to be of importance in these processes, the actual compounds may be different from those discussed here. Nevertheless, enough circumstantial evidence is at hand to warrant further study.

# OBITUARIES

## Prof. T. C. Hodson

Thomas Callan Hodson, who died at his home in Tisbury, Wiltshire, on January 26, aged eighty-one, was born at Hornsey, Middlesex, in December 1871. He was the son of Arthur Hodson, R.N., and Mary Catherine Hodson *née* Callan. The eldest of six children, he went to school at Christ's Hospital, where he became a Grecian, and left in 1890 to go to Queen's College, Oxford, with an Eglesfield scholarship. He took no degree at Oxford, but he competed successfully in 1893 for the Indian Civil Service and in 1894 went via Bengal to Assam. He served in the Khasia and Jaintia Hills, and was for some time personal assistant to the Chief Commissioner of Assam, Sir Henry Cotton. He served later on in the Manipur State, where he was president of the Durbar, but retired from the Service in 1901. He was registrar of East London (now Queen Mary) College during 1903–14; from 1914 until 1920 he served with the British Forces in France, and by 1919 had risen to the rank of colonel, and his services were mentioned in dispatches. During 1921–23 he was principal of Hornsey Rise Training College, and after that he lectured on anthropology in Oxford, London, Cambridge and Michigan, ultimately succeeding Dr. A. C. Haddon as reader in ethnology in Cambridge in 1926.

In 1932 the William Wyse chair of social anthropology was created in Cambridge, and Hodson was the first professor to hold it. He was elected to a professorial fellowship at St. Catharine's College, where he became a resident fellow and shared with no little satisfaction to himself and to his colleagues in the corporate life of the College. He had been secretary of the Royal Anthropological Institute during 1912–14, and he was later an associate editor of the "Encyclopædia Britannica" (14th edition). He held the Silver Medal of the Royal Society of Arts.

As an anthropologist, Hodson was particularly interested in the linguistic side of his subject, and his first publication was a grammar of the Thado Kuki language (1906). His knowledge of Manipur and the Manipuris enabled him in 1908 to contribute a monograph on "The Meitheis" to the Assam Government's tribal series, which he followed with "The Naga Tribes of Manipur" in 1911. His lectures at the London School of Oriental Studies, delivered in 1922, were published by the Forlong Fund as "The Primitive Culture of India".

Hodson was endowed with intense industry and an unquenchable activity and persistence. As holder of the chair in Cambridge, he set himself unequivocally to popularize the Tripos of Archæology and Anthropology, and succeeded so well that when he retired in 1937 the numbers had gone up from about a dozen to quite four times that number. But it is on account of his own personality that he will be best remembered: decidedly irascible, very intolerant of control or of opposition, he never forgot a kindness shown to him, and all those who followed his varied and rather stormy vicissitudes combined in admiration of his tenacity and fortitude in what were often very difficult circumstances.

In his family life Hodson was extremely happy. His wife and children were as devoted to him as he was to them, and the successes of his children more than made up for the disappointments of the earlier part of his career.

J. H. HUTTON

## Dr. H. G. Reeves

HARRY GORDON REEVES, senior lecturer in biochemistry in the Medical College of St. Bartholomew's Hospital, London, died on November 22 at the age of fifty-eight, following a recurrence of the severe bronchitis which had caused him considerable discomfort and ill-health in recent winters.

Dr. Reeves's professional career can be divided into two distinct parts. He took his B.Sc. degree with honours in chemistry in 1920 at Birmingham, where he also took the degrees of M.Sc. (1921) and Ph.D. (1924). In the latter year he became a demonstrator in the Physiology Department at King's College, London, and in 1928 he took his D.Sc. degree and became a demonstrator in the Physiology Department at St. Bartholomew's Hospital, a post which entailed heavy and varied teaching duties. Thus Reeves had few further opportunities for doing research; but on the other hand, he acquired a knowledge of all branches of physiology which was to stand him in good stead during his career as a teacher of biochemistry. He made useful contributions to our knowledge of the metabolism of dihydroxyacetone in muscle and other tissues, but it is by his teaching that Gordon Reeves will be remembered.

It was during the second phase of his service at 'Barts', starting in 1936 with his transference to the newly created Department of Biochemistry and Chemistry, that Reeves grew to full stature as a university teacher. Promotion came fairly rapidly. After a short period as demonstrator, he became lecturer and then senior lecturer in biochemistry—a well-deserved recognition of the good work he did during the war-time housing of the Preclinical School at Cambridge and the subsequent period of rehabilitation and expansion in Charterhouse Square.

As a teacher of the fundamentals of biochemistry in relation to medicine, Reeves was first-rate. There is surely a place in academic life for senior teachers of his type, and fortunate is the head of any large department who can call at any time on the services of such a versatile, capable and loyal colleague. Many hundreds of students who have passed through the Preclinical School at 'Barts' have good reason to be grateful to him. His colleagues are the poorer by the loss of a cheerful and ever-willing beloved friend.

A. WORMALL

# NEWS and VIEWS

## Scientific Research and the Ministry of Supply: Sir Harry Garner, K.B.E., C.B.

AFTER thirty-six years of government service, Sir Harry Garner retires on February 21 from his post as chief scientist of the Ministry of Supply, and will be succeeded by Dr. O. H. Wansbrough-Jones. Sir Harry had intended to become an astronomer; but in 1917 the demolishing of his office during an air-raid necessitated his transfer from the Royal Naval Air Service to the Royal Aircraft Factory (now Establishment), and it was there that, by virtue of his mathematical ability, he became known throughout the aeronautical world for his work on the 'Bristol' fighter aeroplane, in which he made the first measurements ever to be taken in flight on the aerodynamic rotary derivatives of an aircraft. He was the first to develop the fundamental techniques for testing sea-planes and flying-boats and of the hydrodynamics of hull design, and he has always been, and still is, a firm believer in the future of the flying-boat. In 1952 he gave the Wilbur Wright Lecture to the Royal Aeronautical Society, his subject being "Prophecy and Achievement in Aeronautics". Sir Harry has been in turn the chief technical officer of the Marine Experimental Establishment, the Aeroplane and Armament Experimental Establishment and the Airborne Forces Experimental Establishment. In 1942 he was made deputy director of scientific research in the Ministry of Aircraft Production, later becoming principal director of scientific research (air) in the Ministry of Supply, and in 1949 he succeeded Sir Ben Lockspeiser as chief scientist. In this last office he has successfully tackled the difficult problem of building up the scientific staff of the Ministry of Supply, despite the severe shortage of scientific workers, and, though pressed to deploy more effort on applied problems, he has insisted that a proper proportion of the staff should continue to tackle fundamental research problems. He has played a leading part in the extension of the scheme for making promotions to the higher grades in the Ministry solely on the scientific merit of a person's work, and he also introduced a scheme whereby university staff are employed in Ministry of Supply research establishments during the summer vacation; this has led to a much wider appreciation of the excellent facilities and conditions of employment in the Scientific Civil Service. Sir Harry retires with the good wishes of a very wide circle of friends that he may now have more time to pursue his wide interests and his hobbies, which include oriental ceramics (on which he is writing a book), music, antique furniture and gardening.

### Dr. O. H. Wansbrough-Jones, C.B., O.B.E.

Dr. Wansbrough-Jones, who has been appointed chief scientist in the Ministry of Supply in succession to Sir Harry Garner, has been since 1951 principal director of scientific research (defence) in the Ministry of Supply. He was educated at Gresham's School, Holt, and Trinity Hall, Cambridge, of which College he was a Fellow and Senior Tutor at the outbreak of the Second World War. He had earlier been a research student of the Goldsmiths and Salters Companies and a Ramsay Memorial Fellow, and he had studied in Berlin under Prof. F. Haber. Dr. Wansbrough-Jones was a demonstrator in the Department of Colloid Science when he left Cambridge for service in the Army. After serving in many advisory and technical posts, mainly in connexion with chemical warfare, he retired from the Army with the rank of brigadier in 1946, his last appointment being that of director of special weapons and vehicles at the War Office. He was then appointed scientific adviser to the Army Council, a post which his military experience and scientific knowledge enabled him to hold with distinction and marked success. In 1951 he was moved from the War Office to the Ministry of Supply at a time of heavy increase in the activities of the Ministry, and he has held up to the present an important executive post there. This recent experience coupled with his previous work as a scientific adviser have specially fitted him for the post of chief scientist in the Ministry, where his energy, drive and power of application will find full scope.

### Dr. W. Cawood, C.B.E.

Dr. W. Cawood takes over on February 23 from Dr. O. H. Wansbrough-Jones (chief scientist designate) the post of principal director of scientific research (defence) in the Ministry of Supply. After graduating in 1929 at the University of Leeds, Dr. Cawood read for his Ph.D. under Prof. R. Whytlaw-Gray, obtaining this degree in 1931 and at the same time winning the Cohen Prize. He then worked in the Chemical Department of the University until 1938, publishing a large number of papers with H. S. Patterson and R. Whytlaw-Gray on the coagulation and other physical properties of aerosols. He also worked with H. S. Patterson on the stoichiometrical determination of the atomic weights of carbon, xenon, nitrogen and fluorine. This work was the first to predict the existence of the carbon-13 isotope. During this period he was appointed a Ramsay Memorial Fellow (1931–33), and also Moseley Scholar of the Royal Society (1933–38). Dr. Cawood joined the Air Ministry in 1938, and during the Second World War worked on air armament, chemical warfare, bomb-sights and fire control. In 1947 he became deputy director of the Royal Aircraft Establishment, and since then he has made a substantial contribution to the Ministry of Supply programmes on guided weapons, conventional air armament and rocket propulsion, for which work he was awarded the C.B.E. this year. Dr. Cawood's many friends will wish him every success in his new appointment.

### Volta River Aluminium Scheme

The White Paper on the Volta River Aluminium Scheme (Cmd. 8702) reported the agreement of the Gold Coast Government, the United Kingdom Government and the aluminium producers to set up a Preparatory Commission to follow up the work already done. The Gold Coast Government, with the concurrence of the United Kingdom Government, has now appointed Commander R. G. A. Jackson as special commissioner in charge of the Preparatory Commission. The cost of the Commission will in the first instance be met by the Gold Coast Government, but half the cost will be reimbursed by the United Kingdom Government. It is expected that the work of the Commission will take eighteen months to two years. Commander Jackson was responsible for establishing the Ministry of National Development in Australia in 1950. He was attached to the Pakistan Government early in 1952 for consultation on its development plans, and in the latter part of 1952, at the request of the Indian Minister of Finance, advised the Indian Government and Planning Commission on the implementation of the Indian Five-Year Plan and, in particular, the three major hydro-electric and irrigation schemes.

### *British Chemical Abstracts*

In a written answer in reply to a question from Sir Wavell Wakefield in the House of Commons on February 4, the Parliamentary Secretary to the Ministry of Works, as representing the Lord President of the Council, stated that he understood that the Chemical Council would shortly issue an appeal for funds to enable *British Chemical Abstracts* to continue publication during 1953. He added that the Department of Scientific and Industrial Research has already provided £5,000 to enable the Bureau to continue to operate while the appeal is being made and, provided a satisfactory response is forthcoming from industry, the Government is ready to make a further substantial contribution this year.

### Careers in Agricultural Research in Great Britain

A useful pamphlet entitled "Careers in Agricultural Research—Training Grants, Studentships and Fellowships awarded by the Agricultural Research Council, 1953" (pp. 14) has recently been issued by the Agricultural Research Council. There are openings for research workers in many of the twenty-six agricultural research institutes financed by the State. In addition, certain appointments in universities and other research institutions are financed by the Council; many of these are temporary in character, but are particularly attractive to the young worker who wishes to gain experience under the personal guidance of a distinguished man of science. The pamphlet also gives useful information about the scientific staffs of the Council and of the State-aided agricultural research institutes, and about the advisory services. This year the Council is offering for the first time two veterinary clinical fellowships to provide opportunities for suitably qualified veterinary clinicians and pathologists of Ph.D. standing to continue research for two or three years. The fellowships will be renewable annually up to a maximum of three years and will carry a stipend of £850 a year. In addition, the Council is continuing to offer a limited number of junior agricultural research fellowships, carrying a stipend of £600 a year, to research workers of outstanding ability; and a larger number of postgraduate training grants and research studentships in agricultural and veterinary science. Applications for awards should reach the Council by March 20. Further information and a copy of the pamphlet can be obtained on application to the Secretary, Agricultural Research Council, Cunard Building, 15 Regent Street, London, S.W.1.

### German Meteorological Service of the U.S. Zone

The former German meteorological service, the Reichswetterdienst, ceased to exist at the end of the Second World War, and separate meteorological services were set up in each of the Occupation Zones in Germany under the auspices of the respective Occupying Powers. A number of publications of the German Meteorological Service of the United States Zone have now been received. They consist of three series, the *Berichte* which report major researches, a minor series entitled *Mitteilungen*, and finally the 'year-books' containing the record of the observations made at meteorological stations in the Zone. The earlier numbers of the *Berichte* are mostly reports of war-time researches. Of these perhaps the most interesting is No. 1, by G. Schulz, which describes the work of the Cloud Investigation Centre, directed during 1940–45 by W. Findeisen. The work included laboratory research, observations in flight, and a theoretical study on sublimation nuclei, ice accretion on aircraft, temperature, humidity and electrical measurements from aircraft, determination of height of cloud top by balloon-borne apparatus, and condensation trails. Findeisen's researches on the critical temperatures for the formation of ice crystals by the condensation of water vapour in the atmosphere are described in this publication. In No. 3, W. Schwerdtfeger applies the observations made in the war-time meteorological reconnaissance flights over the North Sea and Atlantic in a study of the detailed structure of fronts and the relations between temperature distribution in fronts and the cloud and precipitation. Later numbers include an exhaustive description, by H. Hauer, of the weather and climate of the Zugspitze (2,962 m. above mean sea-level) based on the observations made during the fifty years since the famous mountain observatory was opened in 1900, and works on agricultural meteorology by S. Uhlig, N. Weger and W. Baier. As an example of the last class, No. 28 describes the effects of radiation from walls on growth of plants and of the influence of soil coverings of various types, from fine sand to aluminium foil, on the temperature and humidity of the soil and the air immediately above and on plant-growth.

### Astronomy at Geneva

The issues during recent years of "Publications de l'Observatoire de Genève" (Série A, Astronomie, Chronométrie, Géophysique; Fasc. 37–43, 1946–52) contain a number of short articles on such matters as seismic disturbances and the behaviour of the pendulums at the Observatory, an approximate solution of the motion of the isochronous pendulum, and the first quartz clock at the Geneva Observatory, illustrated with eight figures. No. 39 contains an article regarding the tercentenary of Newton, in which is reproduced a passage from the address presented by the Helvetian Society of Natural Sciences to the Royal Society; No. 40, "A propos du Centenaire de la Découverte de Neptune", reproduces a number of letters written by Gautier to his parents and also some of the correspondence between Le Verrier and Gautier, which show the close collaboration between them; and in No. 42 Pierre Challande gives a short mathematical analysis of the functioning of a quartz resonator in the neighbourhood of the frequency of resonance, illustrated by ten diagrams, and Dr. R. Luthy deals with the radiotelegraphic reception of the hourly signals. Two other "Publications"—"Résultats des Observations de Chronomètres en 1951" and "Série M, Météorologie" (Fasc. 25)—appeared in 1952; the latter gives a résumé of the meteorological results obtained at Geneva in 1951, first for the whole year and then in tabular form for each month from December 1950 to December 1951.

### The Blue-cheeked Bee-eater

A new species of bird, the blue-cheeked bee-eater (*Merops superciliosus*), was added to the British list in 1951. Publication of the record was delayed by the editors of *British Birds* since it was felt that the occasion demanded a specially prepared coloured plate. This has now been prepared by Mr. Roger Tory Peterson, and in a recent issue of the journal it is accompanied by details of the first observation of the bird by Miss Hilda M. Quick on the Scilly Isles in June 1951 (*Brit. Birds*, 45, No. 7; July 1952). The bird is about the size of a cuckoo and has a beautiful iridescent green colour with rather darker primaries. There is a dark copper spot on the throat, a black line through the eye, and the forehead and crown are pale blue. The blue-cheeked bee-eater has occurred as a vagrant in France and Sicily, but Europe is outside its normal range, which includes East Africa, Madagascar, north-west Africa, Egypt, Syria, Iraq and Persia, and most of the Oriental region. It would appear that the bird which Miss Quick saw belonged to the Middle Eastern race, although this is not certain.

### Studies of a Red Alga

In a recent paper, Dr. K. M. Drew (*Phytomorph.*, 2, 38; 1952) has compared collections of the common but insufficiently investigated red alga *Bangia fuscopurpurea* from Wales and Naples, by growing them for several generations, under controlled conditions in the laboratory, in a culture solution consisting of filtered sea-water, soil extract and added mineral nutrients. Reproduction has been by asexual spores throughout. Under identical conditions, marked differences, which are described and illustrated, have been consistently observed between the cultures from the two localities. The indications are that further investigations are required to ascertain if *B. fuscopurpurea* is an aggregate species comprising physiological and morphological races. The point is also made that the methods of spore formation in the genus *Bangia* merit re-examination, particularly with reference to the desirability of using the relevant data as a basis of generic distinction in this group.

### Persistence of *Rhizoctonia solani* in Soil

The effects of different living host and other plants, of various mineral additions to soil (sodium nitrate and calcium hydroxide), and of *Trichoderma lignorum*, with and without added corn meal, on the persistence of a heavy artificial inoculation of *R. solani* in the soil, have been investigated under controlled conditions by G. B. Sanford (*Canad. J. Bot.*, 30, 5, 652; 1952). The amount of disease induced in the host plants was found to be the best means of assessing the extent and persistence of the pathogen in the soil. Also, as the experimental results indicate, this organism depends essentially on parasitic nutrition for its propagation and persistence in the soil. *R. solani* disappeared from the soil in some 120 days when various cereals were planted at intervals of 21 days, but was abundant in soils planted with potatoes, beans and peas. The fungus was not suppressed by heavy inoculations with *Trichoderma lignorum* unless the latter was added with corn meal.

### A Dominant Sex-linked Mutation in the House Mouse

Although evidence for sex-linked mutations in the mouse has been presented by several investigators, only one of these reports involved a morphological mutation. The results of matings of a new dominant mutation in the mouse, Bent-tail, described by E. D. Garber, suggest that this mutation may be sex-linked (*Science*, 116, No. 3004; 1952). The expression of Bent-tail, in the female, may range from a single almost imperceptible kink to a series of well-defined kinks. In some extreme cases, the tail is bent back on itself and may be pressed against the body. In females, the tail is usually normal in length; in males, however, the tail is usually half the normal length, and the kinks are generally restricted to the end of the tail. Except for the kinks and shortness, the tail is apparently normal. A single Bent-tail male was found in a litter of seven mice resulting from a mating between a normal female of the Namru strain and a bald male. This male, mated with a normal sib, produced Bent-tail females and normal males, suggesting that the mutation was dominant and apparently sex-linked. Two females could not be positively identified as Bent-tail because of the poorly defined single kink. These two females when outcrossed to normal Namru males yielded Bent-tail and normal mice. When the original normal female was out-crossed to a normal Namru male, only normal mice resulted. Finally, the original Bent-tail male was outcrossed to three normal Namru females. These matings also indicated that the mutation was sex-linked and dominant.

### A Stain for some Fatty Materials

In a paper in the *Museums Journal* (November 1952), Mr. R. H. Harris, curator in the Museum of Zoology and Comparative Anatomy, University College, London, describes a demonstration which he undertook to define the supporting tissue in the manus of an Indian elephant. A median, sagittal section was prepared so that the cushion of fat and elastic tissue upon which the animal rests its weight could be clearly shown. The dissection was carried out in the fresh state, and, as there was no sharp contrast between the fat, elastic tissue and muscle fibres, it was decided to use a fat stain. This was prepared by adding to a solution composed of equal parts of acetone and 70 per cent alcohol sufficient Sudan III powdered stain to cause saturation. The solution was filtered and kept in a tightly stoppered bottle. Full experimental details are given by Mr. Harris; but the main point is that ultimately only the fat was stained, leaving all other tissues sharply defined. The method renders an anatomical feature in elephants visible for study and research, and the finished dissection provides a valuable museum exhibit.

### Hydroelectric Schemes in North Wales

Under the title "Hydro-electricity in North Wales", the North Wales (Hydro-Electricity) Protection Committee has issued a further illustrated pamphlet (pp. 8+4 pl.; from the Committee, 93*a* Scotland Road, Liverpool 3; 1952; 6*d*.), dealing with the six new schemes now proposed for North Wales and involving the areas Nant Ffrancon, Snowden, Upper Conway, Vale of Festiniog, Mawddach, and Plynlimon or Rheidol. The schemes affect the whole of the mountain country from Bangor to Aberystwyth, with the exception of Cader Idris. The Bill to be promoted by the British Electricity Authority is to cover the Plynlimon scheme, the largest, and the Vale of Festiniog. The pamphlet recapitulates the arguments against the schemes and appeals for financial support for preparing petitions against the Bills; the legal expenses involved in fighting such so-called 'private' Bills are heavy, and several thousand pounds is still required for this purpose.

### International Meetings in Physics

A number of international meetings in various fields of physics will be held this year, and these will include the following: meeting of the International Optical Commission, at Madrid, April 20–21 (Prof. J. M. Otero, Serrano 121, Madrid); International Congress of Acoustics, in Holland (The Hague, Delft, Eindhoven and Hilversum), June 16–24 (C. W. Kosten, Mijnbouwplein 11, Delft); colloquium on cosmic rays, organized by the University of Toulouse, at Bagnères-de-Bigorre, July 5–11 (Prof. L. Leprince-Ringuet, 17 rue Descartes, Paris 5e); symposium on fundamental theoretical physics and executive meeting of the International Union of Pure and Applied Physics, in Japan (Tokyo and Kyoto), September 15–23, under the presidency of Dr. H. Yukawa (Prof. P. Fleury, Institut d'Optique, 3 Boulevard Pasteur, Paris 15e). Further information can be obtained from the persons named in brackets.

### Frank B. Jewett Fellowship Awards

The American Telephone and Telegraph Co. has awarded five Frank B. Jewett fellowships to the following: M. Fixman, a graduate of Washington University, St. Louis, for research at the Massachusetts Institute of Technology on theoretical and experimental aspects of the behaviour of high-polymer molecules in solution, including the statistical mechanics of transport processes particularly involving macromolecules; Dr. H. Helson, a graduate of Harvard University, for the continuation of his work in the Mathematics Department, Yale University, on a clarification of the relations between the Wiener and Kolmogoroff prediction theory and certain questions in analytical function theory which are fundamental to cybernetics and information theory; R. G. Newton, a graduate of the University of Berlin and of Harvard University, for research on the connexion between the quantum field theories and detailed behaviour of nuclei and their effect on surrounding electrons; Dr. R. S. Pierce, a graduate of the California Institute of Technology, for further research on the principles of automatons, clarifying the mathematical fundamentals of how machines can perform near-human operations; and Dr. D. B. Ray, a graduate of Harvard University, for the continuation of his study, up to now conducted at Cornell University, on the essentials of random processes and prediction of events involving atoms and electrons.

These fellowships, which are awarded by a committee from the Bell Telephone Laboratories, are designed to stimulate and assist research in the physical sciences by those who have recently received doctorates or are about to receive them. The stipend is 4,000 dollars to the recipient and 1,500 dollars to the institution at which the research is carried out.

### Colonial Service: Recent Appointments

The following appointments have recently been made in the Colonial Service: J. L. Congdon (agricultural officer, Aden), director of agriculture, Aden; R. A. Silverlock (agricultural survey officer, Gold Coast), agricultural officer, Gold Coast; G. M. Stockley (director of geological survey, Tanganyika), director of geological survey, British Guiana; J. H. Hinds (senior agricultural officer, Gold Coast), pasture research officer, Northern Rhodesia; E. A. Lewis (deputy director, East African Tsetse and Trypanosomiasis Research and Reclamation Organization), director of the Organization; M. B. Noel-Buxton (fisheries officer, Gold Coast), senior fisheries officer, Gold Coast; D. McCallum (education officer, Kenya), meteorologist, East Africa High Commission; L. Piening, plant pathologist, Department of Agriculture, Gold Coast; A. M. M. Rees, agricultural economist, Northern Rhodesia; J. P. Scott, agricultural officer, Sierra Leone; T. E. Tomlinson, scientific officer, Sierra Leone; A. W. Reece, geologist, Uganda; L. R. Boulger, pathologist, Nigeria; B. W. H. Stronach, provincial tsetse officer, Tanganyika; Miss R. V. Suter, microbiologist, Microbiological Research Institute, Trinidad; J. W. Wholey, assistant conservator of forests, Nigeria.

### Announcements

H.M. The Queen has been graciously pleased to grant Her Royal Patronage to the Institution of Gas Engineers.

The Hinchley Medal of the British Association of Chemists has been awarded to Dr. Herbert Levinstein, a trustee and past-president of the Association. The presentation will take place in the West Hall of the Royal Society of Medicine, 1 Wimpole Street, London, W.1, on February 27, at 6.30 p.m., and Dr. Levinstein will speak on "Our Changing Chemical Industries: an Appraisement". Prior to the presentation, there will be a brief opening ceremony at the new headquarters of the Association, at Hinchley House, 14 Harley Street, W.1.

Dr. W. C. J. Ross has been appointed to the readership in chemistry tenable at the Institute of Cancer Research (Royal Cancer Hospital), University of London.

An Easter vacation school in relaxation methods will be held in the Imperial College of Science and Technology, London, during April 9–23. The course will be on the lines of those of previous years and will cover the numerical solution of linear algebraic equations, framework problems, Laplace's and Poisson's equations, the biharmonic equation, eigen-value problems, the heat-conduction equation, three-dimensional relaxation, etc. Lectures will be given in the mornings, and during the afternoons the instruction will consist of solving examples under supervision. The fee for the course is £10. Further information can be obtained from D. N. de G. Allen, Imperial College, London, S.W.7.

A summer school in analytical chemistry, organized by the Royal Institute of Chemistry and the Society of Public Analysts and Other Analytical Chemists and open only to members of these two bodies, will be held in the Royal College of Science and the Royal School of Mines, South Kensington, London, S.W.7, during September 6–12. The course will be divided into three parts, dealing with organic, metallurgical and biochemical analysis, respectively, and there will be one evening meeting on the need for statistical methods in analytical chemistry. The fee for the course is £13 (£3 for the lectures only of any one part); hostel accommodation can be reserved. The course is limited to fifty persons. Further particulars can be obtained from G. Murfitt, at Metals and Methods, Ltd., Bacon Works, Langley, near Slough, Bucks.

The eighteenth Cold Spring Harbor symposium on quantitative biology will be held during June 5–11, the general subject of the meetings being "Viruses". Emphasis will be on discussion of the quantitative aspects of virus research, particularly research with bacterial viruses, and the following problems will be discussed: virus in the vegetative state and its maturation, pro-virus, transition from pro-virus to vegetative virus, transition from the infective to the vegetative state, structure of viruses, biochemical studies of virus infections, host-controlled variations of viruses, and viruses in tissue culture. Further information can be obtained from the Biological Laboratory, Cold Spring Harbor, New York.

As in former years, a course in tropical hygiene for laymen will be held by the Ross Institute of Tropical Hygiene (forming part of the London School of Hygiene and Tropical Medicine) during July 20–24. The course is for workers in the tropics holding, for example, administrative or executive posts, whose responsibilities entail the health and welfare of others. Morning sessions will be devoted to malaria and its control, and in the afternoons other tropical diseases and problems such as hookworm, bilharzia, nutrition, housing and sanitation, and protection against heat will be dealt with. There is no fee for the course. Further information can be obtained from the Organizing Secretary, Ross Institute of Tropical Hygiene, Keppel Street (Gower Street), London, W.C.1.

The Institution of British Agricultural Engineers is offering a scholarship for students who experience financial difficulty in completing their studies during the academic year 1953–54 for the final examination of the National Diploma in Agricultural Engineering. The scholarship, which was given last year by the publishers of *Farm Mechanization*, is tenable at one of the colleges approved by the examination board of the Institution, and preference will be given to candidates with engineering qualifications. Application forms (to be completed by May 15) and further particulars can be obtained from the Secretary of the Institution of British Agricultural Engineers, 24 Portland Place, London, W.1.

Cambridge University Press announces that a list of errata so far discovered in the first edition of "The New Flora of the British Isles" by Clapham, Tutin and Warburg is now available. As most users of "The Flora" will want to transfer the necessary corrections to their copies of the book, the errata slip is being inserted loose in all remaining stock. Booksellers who wish to put the errata slip in their own stock copies, or to supply it to customers who have already bought the book, may have copies free of charge from the Cambridge University Press, Bentley House, 200 Euston Road, London, N.W.1.

# SUPPLY OF LABORATORY ANIMALS

A MEETING of representatives of the supporting societies of the Laboratory Animals Bureau of the Medical Research Council Laboratories, Hampstead, was held at the Royal Society of Medicine on January 22, with Dr. R. Lovell in the chair. The purpose of the meeting was to discuss a paper on "The Supply of Laboratory Animals", by Dr. W. Lane-Petter, the director of the Bureau; the paper had been circulated in advance. The Laboratory Animals Bureau has been established for nearly six years, and already it has gathered much useful, and some alarming, information on the sources of the animals used by physiologists, pharmacologists, etc., in their research work or in their work on the standardization of drugs and sera.

Each year the Home Secretary lays before Parliament a "Return of Experiments performed under the Act 39 and 40 Vict., C. 77". Dr. Lane-Petter's paper quotes the figures in the returns for the years 1939–51. They rise steadily from 954,691 for 1939 to 1,919,424 for 1951, and these figures do not include animals which are not returnable under the Act—for example, the control animals where only those of the experimental group are subjected to procedures "calculated to cause pain", most pregnancy-diagnosis tests, and procedures for the production of sera or other substances obtained from animals for medical, veterinary or scientific purposes. An analysis of figures obtained from various sources (inevitably not very accurate) indicates that mice constitute about 79 per cent of the total number of animals used, involving about 43 per cent of the total cost of the animals. The corresponding figures for rats are 8 and 9 per cent, respectively, for guinea pigs 6 and 18 per cent respectively and, at the other end of the table, for monkeys 0·1 and 7 per cent respectively. A table gives the main uses for which the various species are required: applied medicine (diagnosis of disease, pregnancy tests, serum preparation, serum titration, bio-assay and toxicity tests); and research and teaching (physiology, biochemistry, pharmacology, bacteriology and parasitology, endocrinology, nutrition, experimental surgery and teaching). It indicates that research uses the more expensive animals and that applied medicine has adopted the cheaper animals. These are the costs of the animals before being submitted to any experimental procedure. The behaviour of the animals during their laboratory existence has sometimes shown that it is more economical in the end to buy more expensive but really healthy animals than cheaper, less healthy ones. Nearly always home breeding is more expensive than buying from dealers (it would be prohibitive for dogs), and the advantages accruing from such must be weighed against the cost. The commercial breeder probably has lower overhead charges than the scientific breeder, he is probably a better business man and is much more of a specialist in his job. On the other hand, where litter-mate animals are required or animals from parents with a special dietary history, the only absolutely reliable way of obtaining them is by home-breeding; and when mice are required for virus chemotherapy or other virological research, they must be produced under conditions too exacting for commercial breeders.

The procuring of animals which are not specially bred by either a commercial breeder or by the laboratory needing them has some difficulties—for example, monkeys are best imported during the warm months, amphibians are most prolific in the late summer, and guinea pigs are often scarce in the early months of the year. Workers may therefore have to plan to carry out their work when supplies are likely to be good. Heavy demands for the more prolific animals, and especially of young ones, can only be met if orders are placed well beforehand to allow extra matings to be made.

It has been suggested that a general breeding station should be established for the supply of animals to the whole of a university or even to groups of universities. This might or might not have some financial advantage; it would certainly have many disadvantages, for, according to a simple principle of public health, the larger the colony the greater the chance of infection coming in and the less the chance of getting rid of it. Another suggestion which can scarcely be taken seriously is that there should be some centralized depot which would receive animals from all sources and distribute them as needed. The objections to this are the obvious difficulties of controlling the supply and demand, the possibility of infection and the slow adjustment of most animals to change of environment.

On the whole, it appears that most needs can be met from commercial sources and that the acquiring of animals from such sources will be more economical than breeding in the laboratory. It is, however, obviously desirable that some recognized authority should be familiar with the various breeding stations, the strains of animals available and their general condition. It should be able to recommend an alternative source of animals to a worker whose usual source has suddenly become unable to supply his needs. Such a central authority does, in fact, already exist in the Laboratory Animals Bureau. Much has already been done; but much remains to be done to encourage different breeders to produce well-defined strains and perhaps to improve existing strains on the lines used in farm-stock practice for upgrading.

The desirability of using 'inbred' strains of such animals as mice is questioned. The Bureau has discovered that many breeders who claim to supply inbred mice do not, in fact, know the real meaning of the term 'inbred', and, until information based on unquestionable 'inbred' strains is obtained, no reliable conclusion as to their desirability can be drawn. It has also been found that it is practically impossible to keep a colony of animals strictly infection-free, but that a high standard of hygiene will keep a colony healthy enough for most purposes.

To enlarge the supply of cats and dogs, a strong plea is put forward that the humane societies should hand over the really unwanted and ownerless animals that they acquire, for these societies are in a much stronger position than dealers and laboratory workers for ensuring that the cats and dogs which they collect are, in fact, unwanted and ownerless.

The discussion of the paper was opened by Prof. R. E. Glover, representing the Royal College of

Veterinary Surgeons, who approved of the Bureau's scheme of accreditation of breeders but emphasized the dangers of enlarging colonies beyond the limits of the personal care by the owner—for example, the increased danger of infection, and the possibly less careful treatment by subordinate staff. The operation of demand versus supply may be leading to price competition and the consequent annihilation of the smaller breeder whose contribution is useful and often very good. Prof. Glover maintained that cost in research work is indeed watched carefully, but the use of expensive animals as well as the cheaper ones has to be investigated in order to discover the best animal for the purpose in view. Commercial firms benefit by the experience of research workers when they take up large-scale production and test their own products. To overcome the difficulty of having a surplus of young animals at a time of year when they are least wanted, he suggested that a large proportion of these young animals in the glut season should be put to breeding so that the total production in the less good breeding season should, in fact, be increased. He thought that decentralization is distinctly advantageous, but that institutes run by universities on not too large a scale by competent scientific workers would afford a chance of studying animal husbandry and animal diseases; the institutes could train really good technicians, and each institute might specialize in one or two particular species. The linking-up of such institutes would obviously be valuable. Prof. Glover pleaded for more investigations into epidemics in animal colonies, particularly those of commercial breeders. A well-qualified research worker associated with some institute where he would have contact with clinicians, bacteriologists, etc., would be able to do most valuable work on animal epidemics.

Dr. C. C. N. Vass, representing the Physiological Society, emphasized the fact that expenditure on animals must be faced. Often the difficulty in experiments on cats and dogs is to get them of a known age. If this could be done by paying a higher price, it must be paid, and, since such an animal might be under observation for two years, the high price would be justifiable and in fact almost negligible.

Dr. H. J. Parish, representing the Pathological Society, agreed to the need of using healthy animals at almost any cost, particularly for such long-time experiments as are involved in work on prophylactics, which work, it might be stressed, is often done for the benefit of animals and not only for human beings.

Dr. S. J. Folley, representing the Biochemical Society, asked if the possibility of using rats in place of cats and dogs has been considered as carefully as possible; but Dr. Vass replied that, for teaching purposes, the rat is often too small an animal.

In reply, Dr. Lane-Petter said that if breeders' colonies are to be larger, they should be housed in separate small buildings; that prices are becoming stabilized; that putting surplus stock in the summer to breeding purposes would be workable; and that, if institutes for animal breeding should be set up by universities, they cannot be expected to produce all the animals needed. He mentioned again the work of the Bureau in visiting commercial breeders and in giving advice on the healthy running of the colonies.

Great appreciation of Dr. Lane-Petter's paper was expressed, and it was unanimously decided that it should be published *in extenso* or even enlarged, if possible in one of the scientific review journals.

# STUDY OF THE BRITISH FLORA DURING 1952

THE discovery, in remote parts of Scotland in recent years, of easily recognized plants such as *Kœnigia islandica* L. and *Diapensia lapponica* L.[1] is sufficient indication that there are still large areas in the British Isles awaiting botanical investigation. During 1952 two more species of northern distribution well known in Scandinavia have been added to our flora.

The finding by Sir Christopher Cox of *Artemisia norvegica* Fr. in north-west Scotland in August has already been announced[2]. Known only from Norway and the northern Urals, it belongs to a circumpolar group of closely related species which are very unlike representatives of the genus previously known from Britain. The other outstanding addition to our list of native species in 1952 is that of a sedge which appears in current Scandinavian literature as *Carex pulchella* (Lönnr.)[3-5]. It is allied to *C. serotina* Mérat (*C. Oederi* auct.), and has been brought to the notice of workers in Britain by Miss E. W. Davies (University College, Leicester). During the summer she found it in several localities in Perthshire and north-west Scotland, and there are specimens in herbaria collected earlier. For reasons of nomenclature she proposes to publish the discovery under an appropriate name which is not the one by which it is known in Scandinavia.

At the annual exhibition meeting of the Botanical Society of the British Isles, arranged in the lecture room of the British Museum (Natural History) (by kind permission of the trustees) on November 29, *Artemisia norvegica* was represented by Norwegian material exhibited by the Department of Botany of the Museum, and *Carex pulchella* by Scottish material in an exhibit prepared by Miss Davies.

Another addition claimed during the year is *Cakile edentula* (Bigel.) Hook. from the coast of north Scotland, the Outer Hebrides and Shetland[6]. Love has shown that while the British *Cakile maritima* Scop. (which is diploid) ranges around the whole coast of Europe and the Mediterranean, the tetraploid North American *C. edentula* occurs in Iceland and the Azores[7]. D. E. Allen (University of Cambridge) exhibited at the meeting British material determined as representing the two species, with drawings illustrating the characters of the leaves and fruits. A sedge from Ben Lawers which appears to be allied to *Carex parallela* (Laest.) Sommerf.[8] shown by N. Y. Sandwith (Royal Botanic Gardens, Kew), and an unnamed *Euphrasia* from Caithness displayed by Dr. E. F. Warburg (Department of Botany, University of Oxford) may, on further investigation, also prove new. An interesting hybrid between *Rumex conglomeratus* Murray and the naturalized South American *Rumex cuneifolius*, Campd., collected by Dr. F. R. Elliston Wright at Braunton Burrows, North Devon, and shown by J. E. Lousley, is apparently new to science.

The exhibition also included examples of important re-discoveries or extensions of range. One of the most interesting of these was *Ononis reclinata* L. collected last June by Miss H. M. Bigwood on the limestone of the Gower Peninsula. The locality is likely to be the one at which it was found by D. Sharpe on September 18, 1828[9], where, in spite of searches by competent botanists, it has not been seen since that date. The only other stations on the mainland are the well-known one in Devon, and the

Mull of Galloway, where it has not been found for many years. During 1952, *Arenaria norvegica* Gunn. was found by E. C. Wallace on basalt scree in what is only the second station on the mainland—the locality is in the Watsonian vice-county Westerness, 97. He also showed *Draba rupestris* R. Br., *Saxifraga rivularis* L., *S. nivalis* L., *Carex atrata* L. and other rare plants new to west Ross-shire. Miss F. E. Crackles exhibited the scarce grass *Calamagrostis neglecta* (Ehrh.) Gaertn. from Leven Canal, south-east Yorkshire, together with specimens of a putative hybrid with *C. canescens* (Weber) Roth., which grew with it[10]. A surprising extension of range was that of the fern *Dryopteris cristata* (L.) A. Gray from Dungeness, shown with other recent discoveries in Kent by F. Rose (Bedford College, University of London). *Limosella subulata* Ives, previously known only from Glamorgan and the vicinity of Portmadoc, was shown as living material from near Towyn, Merioneth, by Miss C. M. Goodman.

Additions to the list of British plants and to our knowledge of their distribution are of considerable interest; but the intensive studies of species, or groups of species, now being carried out represent work of greater fundamental importance. This work is being furthered by the introduction of new techniques over a wide field. It is a healthy sign that workers are adapting methods used in industry and other branches of science. Two exhibits at the 1952 meeting demonstrated the use of punched cards for statistical investigations. One of these, by P. C. Sylvester-Bradley (Department of Geology, University of Sheffield), illustrated the methods to be used in "The British Rose Survey" which he is organizing in collaboration with Dr. R. Melville. It is intended to enlist the help of a considerable number of assistants to score the characters of bushes in random colonies of roses. The characters are to be recorded on a 'Wilmott grid', and analysed by means of the Powers-Samas system of punched card coding. By this means it is hoped to ascertain the degree of 'reticulation' present.

An ingenious card-index system for ecologists was demonstrated by F. Perring and R. G. West (School of Agriculture, Cambridge). This is an attempt to simplify the task of sorting large quantities of ecological data, and the authors have in mind the possibility of such cards being stored in a national repository. Some thirty-five ecological features of the habitat are recorded by clipping out holes around the edges, while there is space in the centre of the card for listing 715 species of plants. By manipulating the cards it is possible to select all those showing any given combination of ecological factors. Watsonian vice-county numbers are used as part of the reference.

The co-ordination of characters within two 'varieties' of *Lathyrus nissolia* L. was shown by Miss M. J. Herbert and J. M. F. Cannon in an interesting three-dimensional graph-model. Three co-ordinates were employed: mean leaf ratio, pod axial diameter, and pod variation index, and the position on the graph of specimens examined was indicated by beads suspended on threads. Those representing "var. A", with a coloured bead to show the characters of the Linnean type specimen, were separated by a wide gap from those of "var. B", which is var. *pubescens* Beck. A map of the distributions in Europe showed that they occupy separate geographical areas, while living cultures indicated differences in the rate of growth.

Dr. H. G. Baker (Department of Botany, University of Leeds) exhibited *Limonium humile* Mill and *L. vulgare* Mill; these show pollen and stigma dimorphism. The former is monomorphic and self-compatible, and the latter dimorphic and self-incompatible—maps showed the relationship between the British and allied monomorphic and dimorphic species. Mrs. Y. Heslop-Harrison demonstrated variation in *Nymphaea alba* L. Dissections made from material collected in widely scattered localities over the British Isles seemed to indicate that the separation of *N. occidentalis* (Ostenf.) Moss is unjustified. An exhibit by P. T. Yeo (University College, Leicester) of *Euphrasia vigursii* Davey suggested that, while this puzzling plant appears on morphological grounds to be a hybrid between *E. anglica* Pugsl. and *E. micrantha* Rchb., it grows in places where it could not have arisen by direct crossing. O. Buckle and Dr. C. T. Prime illustrated the distribution of *Arum neglectum* (Towns.) Ridley in Sussex with a map and fresh material. Prof. T. G. Tutin (University College, Leicester) exhibited *Poa annua* L., *P. infirma* H.B.K. and *P. supina* Schrad., with hybrids between *P. annua* and the other two species. Of the first species he also showed three genetically different ecotypes which he has in cultivation. A. H. G. Alston (Department of Botany, British Museum (Natural History)) exhibited the hybrid ferns *Asplenium* × *Breynii* Retz. and *A.* × *murbeckii* Doerfl. synthesized from their parents by Dr. Meyer, with specimens found wild for comparison.

During 1952 the first original British Flora[11] for a generation was published, and the influence of this was to be seen in several of the exhibits. Dr. E. F. Warburg (Department of Botany, Oxford), one of the authors, showed some of the little-known segregates described in the Flora. D. E. Greenwood (Botany School, Cambridge) illustrated the distribution of two of these, *Salix cinerea* L. and *S. atrocinerea* Brot., in the Cambridge district with useful observations on the correlation of characters. Miss S. Littleboy showed work on *Galeopsis tetrahit* L. and *G. bifida* Boenn.

*Poa palustris* L. has been known in Britain since 1879. M. E. D. Poore and Dr. S. M. Walters (Botany School, University of Cambridge) showed maps marked with the stations from which it is known, and considered the evidence for its status. The localities now include Woodwalton Fen, where it is abundant, but unrecorded until 1950, and Wicken Fen, where it has only recently been verified though doubtfully identified material was collected there in 1941. Dr. Walters also had exhibits illustrating the distribution of *Alchemilla minor* Huds. sec. Wilmott, and, with Miss M. E. Bradshaw, the detailed distribution of species of *Alchemilla* in Teesdale. Other exhibits from the Botany School were: *Cardamine hayneana* (Rikli) Junge by D. E. Allen, *Galium pumilum* Murr. by K. M. Goodway, and *Alisma plantago-aquatica* L. and *A. lanceolatum* With. by C. A. Priestley. Further exhibits of small groups included: hybrid carices by Miss E. W. Davies, the affinities of *Catabrosa aquatica* L. by M. Borrill, and *Ranunculus flammula* L. by Miss P. A. Padmore (all of University College, Leicester); autogamous *Epipactis* in Britain and Scandinavia by Dr. D. P. Young, and *Helianthemum canum* (L.) Baumg. by Miss M. E. Griffiths. K. J. F. Park showed some interesting northern species of *Euphrasia*, Dr. A. Melderis (Department of Botany, British Museum (Natural History)) demonstrated hybrids of the

British *Elytrigia*, and G. O. Allen exhibited British charophytes.

An exhibit of considerable general interest, by W. T. Stearn (Department of Botany, British Museum (Natural History)), illustrated "The creation of new species through hybridisation resulting from man's activity". This included the species which have arisen from *Tragopogon pratensis* L. and *T. porrifolius* L., and the well-known *Spartina townsendii* H. and J. Groves. From the European Herbarium of the Museum were shown type-specimens of *Limonium* and *Rubus*, and material of special interest in connexion with recent field meetings of the Botanical Society. The Library of the Museum provided unpublished illustrations of the British Flora by Miss B. O. Corfe, F. H. Round, E. F. Bedford, Miss Margaret Knox and Miss Ellen Hawkins. J. E. Raven, P. D. Sell and Dr. C. West exhibited a series of specimens of little-known British *Hieracia* set out side by side with paintings by Mr. Raven of the same specimens before they were dried. Mrs. H. N. Clokie (Department of Botany, University of Oxford) had an exhibit dealing with Jacob Bobart the elder (1599–1679) and Jacob Bobart the younger (*c.* 1640–1719).

Limitations of space prevent reference to other exhibits, and the selection has been made on the basis of those which indicate the development of our knowledge of the British flora. It is evident that much of the current research is being carried out by younger workers. Many of them wisely restrict their studies to a single species, or to a small group of species, and these are being investigated in greater detail and from more aspects than would have been possible only a few years ago. Scope for the investigation of the British flora is still great. The record of discoveries and progress of research during 1952 is highly satisfactory.

# NATIONAL PHYSICAL LABORATORY, TEDDINGTON

## ANNUAL REPORT FOR 1951

THE annual report for 1951 of the executive committee of the National Physical Laboratory, Teddington, was presented to the meeting of the general board held on May 23 last and has since been published*. It consists of a general survey of the activities of the Laboratory and its various supervisory committees, together with more detailed individual reports, prepared by the respective superintendents or officers-in-charge, of the work undertaken by the ten Divisions, the Electronics Section and the Test House of the Laboratory.

The most important change during the year under review was the transfer of the Engineering Division to the new laboratories of the Mechanical Engineering Research Organization at East Kilbride. Other changes include the closing down of the Statistics Section of the Mathematics Division in order to concentrate on the construction and operation of the Division's two new machines, the ACE (automatic computing engine pilot model) and a 20-integrator differential analyser. No progress was made with the provision of a new ship tank and cavitation tunnel, and the Froude ship research sub-committee has expressed its deep concern at this lack of progress in the provision of what it considers to be equipment essential for the future development of the shipbuilding industry in Great Britain. An interesting development was the appointment of a small sub-committee to consider the possibilities of the utilization of solar energy.

The report states that, at the extensive series of open days, held during May 23–29, 1951, some 3,400 scientific research workers from universities, government departments and industry were invited to visit the Laboratory. On the two days prior to the meeting of the general board, a symposium on recent developments and techniques in the maintenance of standards was held[1] and the proceedings of this symposium have recently been published[2]. Other meetings held during the year included discussions on the properties of iron, on flaw detection and, with thermometer manufacturers, on the types of thermometers which the Laboratory should undertake to test.

The Laboratory took part in several exhibitions of scientific instruments, including the Royal Society soirées, the Physical Society annual exhibition, and the French scientific instrument exhibition at Paris. During the year an illustrated book, "Jubilee Book of the N.P.L.", describing the past and present work of the Laboratory, was published[3]. Other publications were the first booklet, entitled "Gauging and Measuring Screw Threads", in the series "Notes on Applied Science", and No. 1 in the short series of pamphlets dealing with the units and standards of measurement employed at the Laboratory[4]. The Laboratory has continued to receive many scientific and technical visitors from abroad, and both the director, Dr. E. C. Bullard, and senior members of the staff have paid visits to countries overseas to attend conferences or to exchange information with workers in other organizations. In addition to the names of the members of the general board, executive committee and sub-committees, the report lists the names and positions of the senior staff and includes a bibliography of the numerous scientific papers published by the staff during 1951.

The individual reports of the various sections of the Laboratory make interesting reading. The Aerodynamics Division, mainly concerned with problems connected with the design and performance of high-speed aircraft, reports much work in progress on delta and swept-back types of wings. A new high-speed laboratory was under construction, and two high-speed wind tunnels, one 36 in. by 14 in. and the other 25 in. by 20 in., together with a low-turbulence pressurized wind tunnel (8 ft. by 6½ ft.) were being planned. In the Electricity Division two fresh determinations of the ohm, by reference to the primary standards of mutual inductance and frequency, have been made. These agreed with each other to within one part in $10^6$, although they differed from the last set of absolute determinations, made

* Department of Scientific and Industrial Research: National Physical Laboratory. Report for the Year 1951. Pp. 77. (London: H.M.S.O., 1952.) 2s. net.

in 1936, by 15 parts in $10^6$. The change is attributed to a possible variation during the past years in the inductance standard. The Light Division has been mainly occupied with the development of the new methods of producing and copying diffraction gratings suggested by Sir Thomas Merton. Flat gratings with a ruled area of 6 in. by 6 in. have been made, and a special lathe, which will enable larger gratings of particular value to astronomers to be produced, was being constructed.

In the Metallurgy Division, investigations on the influence of the interstitially dissolved elements, oxygen and carbon, on the properties of iron, the elastic and plastic deformation of metals, the creep of high-temperature metals and alloys, and the equilibrium diagrams of alloys of titanium and oxygen and of titanium, iron and oxygen, have proceeded successfully. The Ultrasonics Section of the Physics Division has been concerned with the measurement of the elastic constants of solids by dynamic methods and of the absorption of 'Perspex' and 'Catalin' over the range 1–3 Mc./s. The Radiology Section, in order to establish British absolute standards of various radioactive isotopes, has made intercomparisons of measurements and techniques of several organizations, including the Atomic Energy Research Establishment and the Royal Cancer Hospital. Agreement has been reached on some isotopes.

The bulk of the research carried out in the Radio Division has been on wave propagation, and much basic information has been obtained. The study of ionospheric conditions has continued. Semi-conductors have been given special attention, and noise in germanium diodes and triodes, together with an examination of factors affecting the performance of these valves as rectifiers, amplifiers and oscillators, have been the subjects of investigation. Finally, the report records that the volume of work submitted for test in the Test House has increased appreciably, in some instances by as much as 50 per cent, and the sum received annually from test fees has been almost doubled.

## HUMAN RELATIONS IN INDUSTRY

THE scientific study of human relations in industry has been described by Dr. W. H. Scott, of the University of Liverpool, in two issues of the *Journal of the Institute of Personnel Management* (34, No. 319; March 1952; and 34, No. 321; September 1952).

In the first article Scott examines the nature and aims of the work of the industrial sociologist. The industrial sociologist, he suggests, studies the factory as a social system, as a network of relationships between individuals and groups. The most superficial analysis reveals that these relationships are far more complex than the traditional management–worker antithesis suggests. There are the relationships which exist between persons at various levels in the 'line' organization, from the top executive to the charge-hand; between executive and 'staff' personnel; between rank-and-file employees and their immediate supervisors; between managerial personnel and employee representatives; between rank-and-file employees and employee representatives; and between the various persons at a similar level in the organization as, for example, the members of the 'top' management group, the departmental managers, the foremen, or the rank-and-file employees in a particular department.

Although the sociologist may single out one or more of these particular aspects of relationships for detailed study, all are interdependent to some extent. Thus the relationships between employees and their immediate superiors are influenced by the relationships which exist at higher levels in the 'line', and the relationships between higher managerial personnel and employee representatives are determined to a large extent by relationships within the higher management group itself. It is the recognition of this interdependence which is leading sociologists increasingly to insist that any particular problem of relationships within an organization must be studied, and resolved, in terms of the totality of which it forms only a part. Endeavours to change the behaviour of supervisors by the development of more suitable selection and training procedures, for example, will be of limited value unless such endeavours are made as part of a wider plan to change attitudes and behaviour throughout the 'line' organization as a whole. Moreover, the factory does not exist *in vacuo*, and behaviour within its walls is closely associated with the attitudes and relationships which exist in the wider community.

After considering the difficulties confronting those who wish to investigate social relationships in industry, in his second article Scott discusses some of the contributions of current systematic studies by social scientists.

The common beliefs that efficiency and, concomitantly, productivity, necessarily arise out of individual employee satisfaction or high group morale are shown to lack validity. Social scientists are concerned to discover the conditions under which high productivity and high morale are most likely to co-exist, since under such conditions the satisfaction of the needs of both the individual and the organization will be at its greatest. Evidence is increasing that fuller opportunities for self-development and a greater measure of self-determination in industry are the basic pre-requisites. This does not imply the need for more and more joint consultation; rather is it the day-to-day relationships on the job which are crucial in determining morale and attitudes. The pressing need is for the development of leadership ability and skills at all levels. Leadership at the supervisor–employee level should be integrative, seeking to elicit the maximum contribution from each member of the work team by increasing opportunities for participation and self-development, and by ensuring that the feelings and ideas of all are brought to bear on problems and decisions taken. This will not be achieved simply by developing elaborate schemes for the training of supervisors. Consultative leadership must become an accepted administrative practice at all levels.

The importance of a permissive or consultative, rather than an authoritarian, type of leadership in industry is emphasized by the differences between formal and informal social organization, which sociologists have clarified.

Formal organization defines the division of functions among persons or groups of persons and the relationships deemed necessary for their co-ordination.

It never quite works in the manner prescribed, however, owing to the growth of informal relationships which cut across formal lines at all levels.

In some departments supervisors and even employees may approach their manager directly, while in others a rigid observance of the 'channels' may be insisted upon; foremen in different departments may often arrange matters between themselves without 'going through' their respective managers; staff specialists may achieve a position in which they are regarded as executives, although formally they may have a purely advisory status. Other informal relationships are only indirectly connected with the formal organization, such as the groups which arise among employees who work in close proximity to one another or cliques which have a political or religious basis. It would be erroneous to regard this informal organization as unstable or haphazard, for it usually follows a very definite and persistent pattern, and, like all stable relationships, develops characteristic values, norms, beliefs and attitudes which tend to become stereotyped, to be resistant to change, and to be binding on the members of the group. In a real sense, therefore, the informal organization is the one which matters.

In conclusion, Scott suggests that the more the formal and informal organization can be brought into harmony, the more likelihood there is of achieving a system of social relationships which will be effective both in satisfying individual needs and in attaining common goals.

T. H. Hawkins

## JOURNAL OF EMBRYOLOGY AND EXPERIMENTAL MORPHOLOGY

Growth and change in the needs of scientific publication can often be met by the expansion and alteration of existing learned periodicals, but circumstances may from time to time make the establishment of new journals desirable. In Europe, embryologists, and workers on problems of morphogenesis and developmental change in the adult, have felt the lack of a medium of publication that would both bring together closely related work at present scattered and facilitate the growth of a fruitful co-operation between the many different approaches to the central problems presented by developmental processes.

An attempt to meet this need is being made in the publication of a new quarterly, the *Journal of Embryology and Experimental Morphology*. In founding this journal, the original sponsors, a group of British workers in collaboration with Profs. Sven Hörstadius (Uppsala), Chr. P. Raven (Utrecht) and M. W. Woerdeman (Amsterdam) have taken the opportunity of ensuring a fuller measure of international control of its scientific policy than is generally regarded as practicable. The editorial board, which has at present representation from Belgium, Finland, France, Great Britain, Holland, Italy, Sweden and Switzerland, will determine long-term scientific policy as well as giving the editor (M. Abercrombie) active support in carrying it out.

The editorial board met for the first time on January 3 at University College, London. British members were joined by Profs. A. M. Dalcq (Brussels), A. Stefanelli (Rome) and E. C. Wolff (Strasbourg).

Reports from the chairman (Prof. J. Z. Young) and the editor showed that it would be possible to publish four parts in 1953 and that the first issue could be expected during the spring. As was to be expected of an inaugural meeting, a certain amount of discussion centred on problems of a technical and administrative nature; but perhaps the most important discussions were those in which the scientific policy and scope of the journal were defined. There was general agreement that studies on embryogenesis, on regeneration, on growth, and on developmental changes in the older organism as well as on the physiology of fœtal–maternal relations would all fall within the scope of the journal. Parts of other fields, notably sexual endocrinology, the cytology of gametogenesis, and developmental genetics, would, in their ontogenetic aspects, be served. On the other hand, studies in these subjects which were directed primarily to clinical ends, or were otherwise better published in existing journals, would not normally be taken.

Although English will be the usual language of articles in the journal, provision has been made for the acceptance of a number in French and German; and although articles will, for the most part, be reports of original researches, review articles of exceptional value may occasionally be accepted.

The editorial board will meet annually, and it is hoped that its future meetings will not only review the work of the journal but will also be the occasion of the interchange of scientific information. If this happens the journal may well come to serve its field of biology in two of the most important ways open to it: by providing a common public ground in its pages for research into developmental processes; and by encouraging the international exchange of opinion and knowledge through the less formal means of discussions associated with editorial board meetings.

Members of the editorial board are sensible of their indebtedness to the outside bodies who have made the journal possible. In particular, the Company of Biologists, Ltd., which will publish it, and the Clarendon Press, which will produce it, have provided the basis for the whole project, while the British Council has helped to realize one of its most important features, namely, the participation of workers from many countries in the work of the editorial board meeting.

## VARIABILITY OF INTERNAL ENVIRONMENT AND THE MECHANISMS OF BIOLOGICAL* CORRELATIONS

By EUGENE SCHREIDER

Laboratoire d'Anthropologie Physique, 1 rue René Panhard, Paris 13e

It is generally accepted that internal environment is practically constant. The theory of homeostasis reinforced this old belief, for in its original form it stressed the very narrow limits of biological variations. To-day we can read that in vertebrates even the blood pressure is constant. But variability can now be classified as 'narrow' or 'wide'; we can compare coefficients of variation taken from different biological fields. If we find that they are significantly lower for physiological than for other characters, the relative fixity of internal environment should be accepted; otherwise it must be rejected as a misleading formula.

Table 1 contains a selection from the data which have been assembled; it mentions also the authors from whose works coefficients of variation (or arithmetical means and standard deviations used for calculating them) were taken.

Among the anthropometrical data, stature is one of the least and chest-depth one of the most variable. It is clear that, with the exception of serum chloride and sodium, the variability of physiological and biochemical characters is as wide as, and often wider than, the variability of anatomical measurements.

Since in classical works variability is usually expressed in terms of 'limits', it may be useful to point out the following fact: The ratio maximum/minimum value for human stature rarely exceeds 1·25. The same ratio for hydrogen ion concentration in human blood is 1·51. Perhaps we should conclude that body-height is subject to 'infinitesimal variations' only.

There is another, perhaps more important, approach to the same problem. The large inter-individual variability does not mean that intra-individual variation is high. The latter can be tested indirectly by coefficients of reliability calculated between two sets of measurements taken on two successive occasions on the same individuals. The reliability of anthropometrical characters is well known to be very high. The position is very different with many physiological and biochemical characters (Table 2).

TABLE 2

| Sources | | Coefficients of reliability ($r$) |
|---|---|---|
| | (*a*) *Human subjects* | |
| Goldstein, 1935 | Cholesterol | 0·67 |
| Tanner, 1951 | Cholesterol | 0·85 |
| Salit and Tuttle, 1944 | Heart-rate | 0·63 |
| Tanner, 1951 | Heart-rate | 0·60 |
| " | Respiratory-rate | 0·59 |
| " | Rectal temperature | 0·59 |
| Shock and Yiengst, 1950 | Blood pH | 0·36 |
| Goldstein, 1935 | Blood sugar | 0·37 |
| " | Serum calcium | 0·15 |
| " | Blood creatinine | −0·02 |
| " | Serum chlorides | −0·08 |
| " | Plasma inorganic phosphorus | −0·16 |
| | (*b*) *Dogs* | |
| Schreider, unpublished | Blood sugar | 0·01 |
| " " | Serum potassium | 0·07 |
| " " | Serum calcium | 0·29 |
| " " | Cerebrospinal sugar | 0·24 |
| " " | Cerebrospinal potassium | 0·13 |
| " " | Cerebrospinal calcium | 0·06 |

The serum cholesterol level appears to be one of the most stable biochemical characters. But it is far from 'fixity'. The reliability of other characters is lower, and sometimes the coefficient is zero.

The direct study of intra-individual variability is very difficult because most individuals are unwilling to give a sufficient number of blood samples. Nevertheless, the few data I was able to collect show that for some biochemical characters as many as fifteen to twenty determinations on different days may be needed in order to find a distinct modal value, that is, the value which is really characteristic for a given individual.

It is obvious that the postulate of fixity must be rejected on biometrical grounds. Perhaps this conclusion is distressing for those who put their faith in the 'fixité du milieu intérieur'. But even in the present state of knowledge, it helps us to understand some biological facts.

The lack of correlation between two characters may mean that the intra-individual variability of one of them or both prevents their actual relationship from being detected. On the other hand, intra-individual variability (or low reliability) does not necessarily preclude a character from having obvious correlations. The result of a single determination can be fortuitous; but as there is a mode, there is also a probability that we shall obtain a value more or less characteristic for a given individual. For some characters real correlations must be higher than those actually observed when these are derived from a single determination.

Of course, the lack of correlation can also mean that two characters vary quite independently. We must also become accustomed to the idea that biological correlations are frequently low or non-existent. Survival needs 'elasticity', that is, rather wide variability of the internal environment; it needs also some physiological decentralization: it seems that, in the course of time, antistochastic mechanisms have evolved, for in many cases perfect correlations would be lethal.

Properly speaking, a living organism contains a score of internal environments more or less separated by 'barriers' the function of which partly consists in lowering and breaking down correlations. The figures of Table 3 illustrate this phenomenon.

TABLE 3 (adult men)

| Variates | $r$ |
|---|---|
| Blood sugar and cerebrospinal sugar ($n = 40$) | 0·48 |
| Serum calcium and cerebrospinal calcium ($n = 50$) | 0·51 |
| Serum potassium and cerebrospinal potassium ($n = 47$) | 0·51 |

For a single biochemical trait, the 'between environments' correlation is about 0·50. This means that only 25 per cent of cerebrospinal sugar (or potassium, or calcium) variance is tied to the variations of the same character in the blood. These results are very incomplete, but they suggest a most important line of research. Biometry is the study of variation and related phenomena. The biometrician tries to overcome the disorder of things with the help of statistical tools. But first of all, the disorder should be studied as such.

A more complete statistical treatment of all the data assembled, with detailed references concerning the sources of the figures used, will be published later. [July 10.

# PREPUPAL MOULT IN THE BLOWFLY (*CALLIPHORA ERYTHROCEPHALA*)

By Dr. P. TATE

Molteno Institute, Cambridge

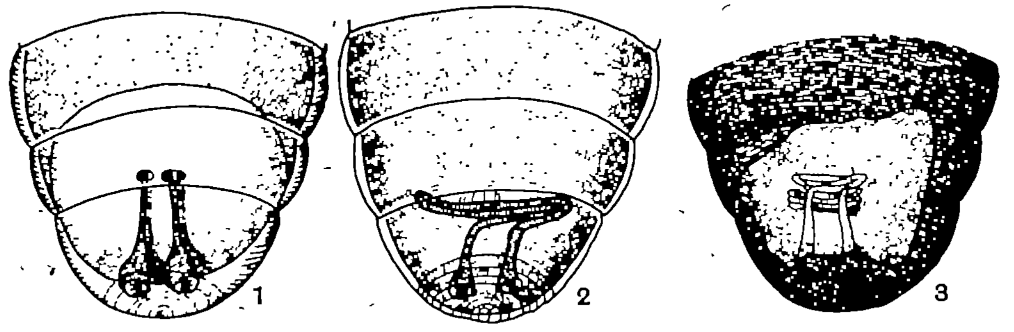
THE occurrence of a fourth, prepupal, moult in cyclorrhaphous dipterous larvæ was first established by Snodgrass[1] for *Rhagoletis pomonella* Walsh. This moult separates the so-called pre-pupa from the true pupa. Fraenkel[2] observed a similar moult within the puparia of *Calliphora*, *Lucilia*, *Phormia* and *Sarcophaga*; but he believed that the prepupal cuticle covered only the abdomen and did not extend forward beyond the line of cleavage between the third thoracic and first abdominal segments of the puparium.

The problem has been re-investigated in puparia of *Calliphora erythrocephala*, which were selected immediately the larvæ had become immobile (white pupæ) and were thereafter incubated in a thermostat at 24° C. to ensure uniform development and to make it possible to obtain the various stages of moulting at will. Under these conditions the fourth moult occurs between 22 and 28 hours from puparial formation. Puparia of the desired age were fixed to microscope slides by cellulose acetate cement and were dissected while alive by slicing off the top of the puparium with a razor blade. The fourth cuticle is extremely delicate; but with care the top half of the puparium can be dissected away to reveal the fourth cuticle enveloping the pupa and separated from the puparium by ecdysial fluid. If the exposed prepupa is flooded with indian ink, or Delafield's hæmatoxylin, the fourth cuticle, which is hydrophilic, takes up the stain, whereas the pupal cuticle is strongly hydrofugal and does not stain. Thus the fourth cuticle is made easily visible and it can be seen to envelop the pupa completely. The fourth cuticle remains attached to the puparium at the lines of cleavage and at the points of attachment of the mouth, anus, anterior and posterior spiracles and the non-functional 3rd thoracic and 7th abdominal spiracles of the third instar larva. In the thoracic region the moult occurs earlier than over the abdomen and, as it quickly becomes affixed to the inner wall of the puparium in this region, it is very difficult to detect.

A more interesting problem, however, and one which does not seem to have been considered hitherto, is how the pupa succeeds in casting the long main tracheal trunks, considering that this fourth moult takes place within the rigid puparium, which would prevent the enclosed pupa from withdrawing the tracheæ in a direct manner. Attempts to solve this problem by observation of the living pupa through 'windows' cut in the puparium were only partially successful; but it was found that if the puparia are coated with mineral oil, or still better, with immersion oil, the puparium becomes sufficiently transparent under intense incident illumination to allow the main features of the fourth ecdysis and, indeed, of the evagination of the head and the extrusion of the pupal respiratory horns, to be followed in the living pupa. Provided the spiracles are not occluded, this treatment with immersion oil does not interfere with the development of the pupa, and flies regularly emerged from coated puparia.

The most easily observed and most interesting part of the process of moulting is that associated with the withdrawal of the posterior part of the main lateral tracheal trunks. The first sign of moulting is the appearance of a bubble of air, surrounding the post-abdominal spiracles, between the pupa and the fourth (prepupal) cuticle. This air bubble enlarges and presses the cuticle against the puparium as the pupal abdomen contracts towards the anterior. During this contraction, which is not uniform but is accompanied by minor movements of contraction and relaxation, the main tracheal trunks are drawn out and extend in an oblique manner from the postero-dorsal surface of the 8th abdominal segment of the pupa to the point of attachment of the post-abdominal spiracles on the puparium (Fig. 1). The contraction reaches its maximum when the posterior end of the pupa is about level with the anterior margin of the 7th abdominal segment of the puparium. This is the maximum withdrawal that can be done by direct contraction, but it leaves much more of the tracheal trunks to be extracted. This phase lasts about an hour. The contracted pupa relaxes and then extends back to the posterior end of the puparium. Meanwhile, the air is transferred to the anterior end by the forward passage of bubbles owing to violent peristaltic contractions of the pupa, and, as it reaches the anterior end, the head is evaginated and the pupal horns are moved back to come beneath the windows in the puparium preparatory to being extruded through them.

The backwards movement of the pupa fills the posterior part of the puparium completely, and, as it does so, the stretched tracheal trunks shorten and are pressed against the inner surface of the postero-dorsal part of the fourth cuticle. Owing to the stickiness of the inner surface of this cuticle, they stick firmly to it whereas they do not adhere to the pupal cuticle, which is smooth and hydrofugal. The pupa then begins to make violent turning and



Figs. 1–3. Dorsal aspect of the three posterior segments of a puparium of *C. erythrocephala* during the fourth, or prepupal moult. The puparium was coated with immersion oil, and Figs. 1–2 show the pupa by transparency through the puparium. In Fig. 3 the dorsal wall of the puparium has been cut away to form a window which is spanned by the fourth cuticle, glued to which are the cast and folded tracheal trunks

Fig. 1 represents the maximum contraction of the pupa and direct withdrawal of the tracheal trunks at 28-hr. incubation at 24° C. Fig. 2, about twenty-five minutes later, shows the posterior parts of the tracheal trunks glued to the fourth cuticle and further lengths of the trunks being pulled out by the sideways writhing movements of the pupa. Fig. 3, about one hour later, shows the fully withdrawn tracheal trunks neatly folded against the inner surface of the fourth cuticle

writhing movements, swaying from side to side in a semi-rotatory manner within the puparium, and, with each lateral movement, a further length of tracheal trunk is drawn out and becomes stuck to the inner surface of the fourth moult to form loops overlapping transversely the portions drawn out by the first contraction which lie longitudinally (Fig. 2). Finally, the trunks are completely withdrawn and remain neatly folded on the inner surface of the fourth cuticle (Fig. 3). Details of the folding and final withdrawal of the tracheæ are difficult to observe as movements during this phase are rapid, and once the tracheæ come in contact with the fourth cuticle, they become wetted, lose their air contents, and are then not easily seen. The final stages can be seen best if the puparium is carefully cut away on the dorsal surface of the last two segments, leaving the fourth cuticle intact. In older puparia this is the only region where the cuticle remains separate from the puparium, and it forms a delicate iridescent membrane stretching obliquely across the postero-dorsal part of the puparium. The lateral abdominal tracheæ are withdrawn and folded in a similar manner by contractions and relaxations of the abdomen; but in them the folds are in line with the axis of the puparium and are not transverse as is the case with the posterior tracheæ.

The characteristic folded arrangement of the tracheæ from the posterior spiracles was noted by Snodgrass[1], who aptly described them as having "the form of a double-stalked T" and further states ". . . but it is difficult to understand how the posterior tubes can acquire their curious arrangement (Pl. 6.E) unless the pupa sways its abdomen sidewise to extract them". As has been shown above, this is in fact what happens in *Calliphora erythrocephala*. It may be noted, however, that in the figure cited by Snodgrass the overlapping of the tracheæ is wrongly shown, as in that figure the wide posterior parts of the tracheæ are shown to be ventral to the thinner, more proximal, parts which emerge last. In fact, it is the wide posterior parts which are withdrawn first and become glued to the fourth cuticle; and the thinner parts are then withdrawn and lie folded beneath, and transversely crossing-over, the wider posterior trunks. The swaying mechanism could not cause the folding to occur in the manner shown in Snodgrass's figure.

The time of onset of the fourth moult, at 24° C., from the so-called 'white pupa' stage is about twenty-two hours, and the whole process may take three hours or more. The first phase, to the maximum contraction of the pupa, takes about one hour; the pressing of the trunks against the cuticle by the backwards movement of the pupal abdomen may take as little as twenty minutes, and the final phase, the swaying of the abdomen and the withdrawal and folding of the remaining part of the tracheal trunks, may be completed in about forty minutes, although sometimes it takes much longer. During the whole of this period of at least several hours, the pupa is undergoing very active and vigorous muscular activity, the abdomen constantly performing contractions and relaxations and twisting and writhing movements. Thus, it is not correct to regard the puparial stage as an entirely quiescent one, as is often assumed in studies on the oxygen uptake of pupæ.

The essential features of the process of casting of the main tracheal trunks during the prepupal moult within the rigid puparium may be summarized as follows. (1) The persisting attachment of the tracheal trunks during the prepupal stage to the posterior spiracles of the puparium. (2) The contraction of the pupa and the appearance of an air space between the pupa and the fourth cuticle, resulting in the direct withdrawal of the first part of the main tracheal trunks. (3) The relaxation of the pupa and its movement backwards to bring the extracted parts of the tracheal trunks in contact with the inner surface of the fourth cuticle. (4) The 'stickiness' of the inner surface of the fourth cuticle, whereby the tracheal trunks become stuck to it when they are pressed against it. (5) The fixing of the cast parts of the tracheæ to the cuticle allows further lengths to be drawn out by the swaying and turning movements of the abdomen of the pupa. These lengths in turn become glued to the cuticle, so that the tracheal trunks are drawn out in relays and become fixed to the inner surface of the fourth cuticle in transverse loops to form a neatly folded mass crossing and recrossing the portions first drawn out which lie longitudinally against the fourth cuticle.

## Cephalosporin *N*: a New Type of Penicillin

A SPECIES of *Cephalosporium* has been found to produce two different kinds of antibacterial substance[1,2]. The first consists of a group of acidic antibiotics which are soluble in common organic solvents, are active mainly against Gram-positive organisms[3], and show similarities to helvolic acid[3-4]. The second consists of a substance (or group of substances) which is insoluble in most organic solvents and is active against a number of Gram-positive and Gram-negative organisms. This has been called 'cephalosporin *N*'. Evidence has now been obtained that cephalosporin *N* is a new type of penicillin.

The reasons for believing that the antibiotic is a penicillin are:

(1) It was inactivated by preparations of the enzyme penicillinase in high dilution, and, like benzylpenicillin[5], it stimulated the adaptive production of penicillinase by suspensions of *Bacillus cereus*.

(2) It was rapidly inactivated at room temperature in aqueous solution below *p*H 4 or above *p*H 9, and also at *p*H 7 in the presence of heavy metal ions such as those of copper, lead and tin.

(3) Acid hydrolysis of purified material resulted in the liberation of carbon dioxide. On addition of mercuric chloride to the hydrolysate a mercaptide was precipitated. Decomposition of the latter with hydrogen sulphide and reaction of the product with hot acetone yielded the hydrochloride of *iso*propylidenepenicillamine[6] (2,2-5,5-tetramethylthiazolidine-4-carboxylic acid), melting point 198°, $[\alpha]^{22}_{D} = +94°$ (found: C, 40·6; H, 7·7; N, 6·0; S, 12·4; Cl, 14·8 per cent; $C_8H_{15}O_2NS,HCl,1/2H_2O$ requires: C, 40·9; H, 7·3; N, 6·0; S, 13·6; Cl, 15·1 per cent). After boiling with dilute hydrochloric acid a solution of the *iso*propylidenepenicillamine hydrochloride showed a strong nitroprusside reaction, and evaporation *in vacuo* yielded the crystalline hydrochloride of penicillamine (β-thiolvaline)[6]. Oxidation of the latter with bromine resulted in the formation of penicillaminic acid (ββ-dimethylcysteic acid).

On addition of 2 : 4-dinitrophenylhydrazine in 2*N* hydrochloric acid to the supernatant from the mercaptide, only a very low yield of a precipitate consisting of a mixture of 2 : 4-dinitrophenylhydrazones was obtained. A small proportion of this precipitate was soluble in carbon tetrachloride and crystallized in orange-coloured needles from aqueous ethanol, melting point 183–185° (found: C, 48·2; H, 4·8 per cent). The 2 : 4-dinitrophenylhydrazone of *iso*butyraldehyde, melting point 182°, requires C, 47·6, H, 4·8 per cent. A further small proportion of the precipitate, which separated in crystalline form from cold pyridine, was glyoxal *bis*-2 : 4-dinitrophenylhydrazone[6].

The thiazolidine hydrochloride, penicillamine hydrochloride, penicillaminic acid and glyoxal *bis*-2 : 4-dinitrophenylhydrazone were kindly identified by X-ray powder photographs by Dr. D. Hodgkin, Miss P. Cowan and Dr. J. Robertson.

Cephalosporin *N* differs strikingly from the common penicillins in its hydrophilic character and its antibacterial activity. It behaves like an acidic substance on ion-exchange resins, and ionophoresis on paper shows that it carries a negative charge at *p*H 6–7. However, the purest preparations so far available contain a basic group titrating in the *p*H range 8–11, and the way in which the partition coefficient of the activity varies with *p*H in the phenol–water system indicates that a basic group, as well as acidic groups, may be present in the active substance itself. To explain the fact that the antibiotic is only soluble in highly polar solvents, it would seem necessary to assume that the essential core of the penicillin structure is linked to a residue which is rich in hydroxyl groups and/or contains a basic group which confers a zwitterionic character on the molecule. The nature of this residue is under investigation.

Cephalosporin *N* shows activity of the same order of magnitude against a number of Gram-positive and Gram-negative bacteria. For example, its activity against a strain of *Staph. aureus* is similar to that against a strain of *Salm. typhi*, whereas benzylpenicillin is more than a hundred times as active against the former as against the latter. An attempt has been made to obtain some idea of the purity of the present preparations of cephalosporin *N* by the application of two chemical methods for assaying penicillin[7,8] and by measuring the carbon dioxide evolved on hydrolysis. The results of these procedures agree in indicating that the preparations contain about 35 per cent of active material if the latter has the same molecular weight as sodium benzylpenicillin. Alternatively, they contain nearly 100 per cent of active material if the molecular weight is about 1,000. On the basis of these results, it appears likely that the activity of pure cephalosporin *N* against many Gram-negative bacteria will be of the same order as that of benzylpenicillin. The relatively low activity of the antibiotic against Gram-positive bacteria suggests that it reaches the sensitive part of these organisms much less readily than the other penicillins.

It is of interest that *Cephalosporium salmosynnematum* and certain other members of the genus *Cephalosporium* have been found to produce an antibiotic called 'synnematin', which is active against a number of Gram-positive and Gram-negative bacteria[9,10]. Although no evidence has been published to indicate that synnematin is a penicillin, the data which are available about its physical and chemical properties do not distinguish it from cephalosporin *N*.

We are indebted to the director and staff of the Antibiotics Research Station, Clevedon, Somerset, for the production of cephalosporin *N*.

## A New Antifungal Substance of Fungal Origin

From a mould filtrate we have extracted a new substance with strong antifungal properties. The mould itself, which we were unable to classify completely, belongs to the species *Monosporium bonorden* and has been isolated from a sample of soil from the Belgian Congo. It develops white, almost sterile mycelia on Czapec-agar, with the reverse of the colonies varying from straw-yellow to brown with age.

The best production of active substance is obtained on Czapec–Dox medium after six days at 27° C. Extraction must be carried out by cold chloroform (5 per cent by volume of the filtrate) because the substance loses its activity rapidly when boiled in organic solvents during continuous extraction.

The residue of the chloroform extraction may be recrystallized from chloroform, alcohol or benzene, yielding about 250 mgm./litre of colourless crystals melting at 193·5° C.

By incorporating the active substance into Czapec-agar medium, growth of many moulds was completely inhibited at the following concentrations: at 25 p.p.m., *Penicillium brevi compactum*, *Aspergillus itaconitus* and *Ascochyta pisi*; at 50 p.p.m., *Botrytis cinerea*; and at 100 p.p.m., *Alternaria solani*. The substance shows a pronounced selectivity towards the mould species, for a concentration of 500 p.p.m. was not enough to inhibit the growth of *Penicillium rubrum* Stoll and *Fusarium solani phaseoli*.

By application of the 'slide germination method'[1] spore germination of *Penicillium cyclopium* Westling and *Penicillium stoloniferum* Thom was completely prevented by a concentration as low as 5 p.p.m.

At $p$H 7 the activity is not affected by sterilization for 5 min. at 105° C.

Against bacteria, concentrations of 200, 200 and 1,000 p.p.m. were required to inhibit the growth of, respectively, *Bacillus mycoides*, *T.B.C.* and *Staphylococcus aureus* during 24 hr. at 37° C. Seven other species of bacteria were not affected by concentrations up to 4,000 p.p.m. The substance is optically active, $[\alpha]_D^{20} = +203°$ in chloroform, and contains only carbon, hydrogen and oxygen. Molecular weight determinations gave, by different methods: 323, 332 and 337. Semimicro analyses gave: C, 60·40 and 60·41 per cent; and H, 4·81 and 4·75 per cent, leading to the empirical formula $C_{17}H_{18}O_7$.

The presence has been detected of two phenolic hydroxyl groups, one active hydrogen on an aromatic ring, one double link in a side-chain and a free carboxyl group. Ferric chloride produces a violet colour. The substance is almost insoluble in water but dissolves readily in dilute alkalis giving a yellow solution.

Acetylation and benzoylation give, respectively, a diacetate of melting point 189° C. and a dibenzoate of melting point 215° C., neither of which showed antifungal properties. Linking the substance with diazosulphanilic acid gives a brick-red pigment of melting point 123° C. with the same antifungal properties as the original substance. Oxidation with alkaline potassium permanganate breaks up the molecule, and one of the products isolated has been identified as succinic acid.

The analyses and chemical properties of the new antifungal substance we have isolated indicate that its molecular structure may be closely related to the structure proposed for mycophenolic acid[2], an antibiotic extracted from *Penicillium brevi compactum*[3]. Further experiments are being carried out to confirm this relationship.

## Ribose and the Maillard Reaction in Fish Muscle

The occurrence and control of the Maillard reaction has been studied fairly thoroughly in dehydrated milk, eggs, fruits and vegetables; but little information is available concerning its prevalence in flesh foods. It has been shown in previous work that moist fish flesh usually becomes brown during exposure to high temperatures (for example, 120° C. for 1 hr.), and that this alteration is due to reactions of the Maillard type[1]. The nature of the sugar or substance contributing the aldehyde groups essential for these reactions was not ascertained. The present investigation indicates that ribose is responsible.

It was found convenient to determine the relative intensity of browning in heated muscle of white-fleshed fish by use of a Beckman model *DU* spectrophotometer equipped with a reflectance accessory attachment. As an arbitrary standard a 'white' surface made by blending 4 per cent high-viscosity carboxymethylcellulose and 2·5 per cent magnesium carbonate with water was used. The percentage of light reflected from the surface of heated fish samples was referred to this standard set as 100 per cent, a wave-length of 500 mμ being used.

It was found initially that the muscle of the sea fish examined had a total pentose content which often exceeded 1,500 μgm. per gm. of wet weight. This is probably associated with, or derived from, the nucleic acid of fish muscle nucleotropomyosin[2]. Since tests[3] of aqueous extracts of the muscle for deoxyribonucleic acid were negative, it was reasonably certain that deoxyribose was absent, thus verifying other work[3].

For comparative studies, muscle of halibut (*Hippoglossus stenolepis*), which browns very slightly on heating at 120° C. for 1 hr., was compared with that of lingood (*Ophiodon elongatus*), which, in common with local species of flounders and *Sebastodes*, browns markedly on heating. With lingood muscle, total pentose, as determined using a trichloracetic acid extract[2], decreased considerably after heating for 1 hr. at 120° C.; but there was no appreciable further loss after an additional 2-hr. heating. On the other hand, with halibut there was very little measurable loss of total pentose even after heating for 3 hr. When 1,000 μgm. of D-ribose was added per gm. of either halibut or lingood muscle, it could no longer be recovered from the heated flesh. These findings indicated that only free and not combined pentose was inactivated in heated muscle. In addition, it was found that the ribosides guanosine, uridine and adenosine did not occasion an increase in browning of heated muscle as did ribose itself.

Preliminary attempts to show that free ribose was responsible for browning in heated muscle were not successful, for only small amounts of ribose were found in extracts of muscle which had been dried *in vacuo* over sulphuric acid overnight. Apparently, most of the ribose combines with free amino groups during the brief drying period, and can no longer be extracted. Extracts of the muscle prepared as follows gave a satisfactory recovery of ribose. Fresh or thawed muscle was blended with 9 volumes of absolute ethanol for 1 min., and 30 ml. of the clear filtrate from the alcoholic extract was concentrated to dryness over sulphuric acid *in vacuo*. The residue, which contained lipoidal matter, was mixed with 1 ml. of water, and the solution applied directly to 28-cm. wide sheets of Whatman No. 1 filter paper for chromatographic separation of the ribose. It appeared that fairly satisfactory chromatographic separation could be effected without desalting the solutions.

In quantitative experiments it was found convenient to apply eight 0·02-ml. spots (in successive applications) of the above extracts at 2·5-cm. intervals along the starting line, qualitative control spots of ribose (5–20 µgm.) or muscle extract being placed near the edges of the paper as qualitative 'markers'. Recovery experiments with D-ribose alone and D-ribose plus the lingcod extract were also carried out. The papers were equilibrated and developed for 16 hr. at room temperature with ethyl acetate – acetic acid – water solvent[4]. After evaporation of the solvent at room temperature, the position of the ribosides present was determined by irradiating the chromatograms with ultra-violet light and marking the dark areas with pencil. It is essential that this be done, so that ribosides, which naturally interfere with the pentose determination, are not cut out with the strip used for determining ribose. Strips containing the 'markers' were cut from along the edges of the chromatograms and the location of the ribose ascertained by spraying with aniline oxalate[5] reagent. This qualitative development always gave very pronounced coloured spots with the lingcod extracts and only very faint spots with those of halibut. To determine the ribose quantitatively, strips 5 cm. wide were cut across the papers to include all the zones corresponding to D-ribose, a similar control strip being cut from another area of the paper which contained no riboside zones. The strips were eluted with 16 ml. of water, the solutions passed through ultra-fine 'Pyrex' sintered-glass filters to remove small particles of filter paper, and ribose determined by Mejbaum's method[6] using duplicate 1-, 2- and 3-ml. portions. The results of a typical experiment are given in the accompanying table, all figures being calculated on the basis of the wet muscle. It will be seen that the amount of ribose which was recovered from the unheated alcoholic muscle extracts after chromatographic separation corresponds closely with that which disappeared when the muscle was heated for 1 hr. at 120° C. The recoveries of chromatographed D-ribose, and of D-ribose plus lingcod muscle extract, were good.

FREE RIBOSE IN HALIBUT AND LINGCOD MUSCLE AND ITS RELATION TO THE BROWNING OF THE HEATED MUSCLE (HEATED HALIBUT MUSCLE = 64 PER CENT REFLECTANCE AND HEATED LINGCOD MUSCLE = 36 PER CENT REFLECTANCE AT 500 Mµ)

| Material chromatographed | Total muscle ribose (µgm./gm.) | Total muscle ribose after heating 1 hr. at 120° C. | Loss of ribose due to heating (µgm./gm.) | Ribose recovered after chromato-graphic separation (µgm.) |
|---|---|---|---|---|
| Halibut muscle extract (0·16 ml. = 0·48 gm. muscle) | 1580<br>1540 | 1530<br>1526 | | 40<br>31 |
| | 1560 | 1528 | 32 | 35·5 |
| Lingcod muscle extract (0·16 ml. = 0·48 gm. muscle) | 1460<br>1406 | 850<br>830 | | 585<br>525 |
| | 1433 | 840 | 593 | 555 |
| 180 µgm. of D-ribose | | | | 186<br>191 |
| | | | | 188·5 |
| 80 µgm. of D-ribose plus 133 µgm. (expected) ribose in lingcod muscle extract* | | | | 220 (213 expected) |

* Calculated from the average ribose content of the lingcod muscle as given in this table.

Though so far D-ribose has not been identified positively by isolation and chemical characterization, it has been observed that only a single spot can be developed when mixed lingcod extract and D-ribose are chromatographed together.

## Myoglobin from Carp Muscle

THE occurrence of myoglobin in fish muscle has been postulated by several authors[1,2]; but no clear evidence for it has been given so far. A red muscular region made of cells rich in sarcoplasm[3] exists, however, in many teleosts underneath the skin; its width is greatest at the level of the lateral line and decreases progressively dorsally and ventrally[4] (Musculus lateralis superficialis Trunci).

Our experiments were carried out with the muscles of these lateral red bands from the carp (*Cyprinus carpio*). The muscles are removed and kept frozen at − 20° C. Before extraction, they are cut into slices 40 µ thick with an automatic freezing microtome and extracted twice for 1 hr. in the cold with 1 vol. water. The turbid reddish extract is easily clarified by dialysis against water and centrifugation; a clear cherry-red solution is obtained which contains all the coloured material of the extract. Electrophoretic analysis of this solution reveals that the red colour migrates as a single peak with a mobility of $-2\cdot5\ (\pm 0\cdot05) \times 10^{-5}$ cm.$^2$/V./sec. at ionic strength 0·15 (0·1 sodium phosphate and 0·05 sodium chloride) and *p*H 7·3. Addition of carp hæmoglobin to a similar extract prepared from white carp muscles shows that the hæmoglobin migrates much more slowly, with half the mobility of the coloured peak of the red muscles. The occurrence in our extracts of a carotenoid rendered water-soluble by attachment to a protein is unlikely; no such complexes appear to exist in fish[5]. It has been suggested by Banks[6] and Bechtold[7] on the basis of preliminary spectroscopic investigations that the cytochrome content of the lateral bands of herring and cod would be particularly high; but the gradient observed cannot correspond to cytochrome *c*, which has an isoelectric point of about 10 (Tint and Reiss[8]). It thus appears that we are dealing with myoglobin.

This identification has been confirmed by the use of Theorell's[9] isolation method. Fish myogen and globulin X are removed at 30° C. from the turbid extract previously mentioned by addition of 0·15 vol. of *M*/2 basic lead acetate, and the excess of lead is removed by solid tertiary phosphate, the *p*H being kept throughout between 7 and 8 by suitable addition of *N* sodium hydroxide or *N* acetic acid. The ionic strength is then increased by addition of a saturated neutral ammonium sulphate solution to a value corresponding to 75 per cent saturation. The amount of coloured material removed at this salt concentration is small. Solid ammonium sulphate is then added up to 95 per cent saturation. The red precipitate obtained is dissolved in water and dialysed against the buffer of ionic strength 0·15 and *p*H 7·3 previously mentioned. Electrophoretic analysis of these preparations reveals the presence of two gradients, the faster coloured one representing about 30 per cent of the total protein concentration. A similar separation is obtained in the ultracentrifuge, the slow-moving peak corresponding to a chromoprotein of a corrected rate of sedimentation of $1·7–1·8 \times 10^{-13}$. A preliminary examination of the visible spectra of these preparations gives three maxima of absorption, one very pronounced at 415 mμ and two much smaller ones at 540 and 575 mμ, in good agreement with the previous determinations of Theorell[10] and others[1] on myoglobin.

Carp myoglobin sediments therefore at approximately the rate of horse, ox and cat myoglobins[11]. Its electrophoretic mobility, however, is very different from that of horse[9] and whale[12] myoglobins and is similar to that of rabbit myoglobin[13], so far as we can judge from the very different experimental conditions used. Its electrophoretic behaviour thus agrees well with the well-known heterogeneity in amino-acid composition of the myoglobins, and its ultracentrifugal behaviour with their apparent similarity in size and shape. From the point of view of comparative biochemistry, it appears also to be widely distributed among fishes, in view of the frequent occurrence of the lateral bands in these primitive vertebrates[4].

Our thanks are due to Profs. M. Dubuisson and V. Desreux for facilities put at our disposal.

## Structure of the Nucleic Acids

We have formulated a structure for the nucleic acids which is compatible with the main features of the X-ray diagram and with the general principles of molecular structure, and which accounts satisfactorily for some of the chemical properties of the substances. The structure involves three intertwined helical polynucleotide chains. Each chain, which is formed by phosphate di-ester groups and linking β-D-ribofuranose or β-D-deoxyribofuranose residues with 3′, 5′ linkages, has approximately twenty-four nucleotide residues in seven turns of the helix. The helixes have the sense of a right-handed screw. The phosphate groups are closely packed about the axis of the molecule, with the pentose residues surrounding them, and the purine and pyrimidine groups projecting radially, their planes being approximately perpendicular to the molecular axis. The operation that converts one residue to the next residue in the polynucleotide chain is rotation by about 105° and translation by 3·4 A.

A detailed description of the structure is appearing in the February 1953 issue of the *Proceedings of the National Academy of Sciences of the United States of America.*

## Non-specific Precipitation of Proteins by Polyhaptenic Dyes

The proteins bovine γ-globulin and human serum albumin were found to give precipitates with the polyhaptenic dyes, 2-methyl-4,6-di(*p*-azobenzenearsonic acid) phenol (III), and 1,3-dihydroxy-2,4,6-tri(*p*-azobenzenearsonic acid) benzene (VI)[1], from *p*H 3·72 to *p*H 0·2–0·3 above the isoelectric points of the proteins, and in sodium acetate – acetic acid buffer of ionic strength either 0·20 or 0·10. Either 0·5 or 1·0 ml. protein solution was added to 0·5 or 1·0 ml. of each of a series of serially diluted dye solutions of initial concentrations of 0·57 (III) and 0·80 per cent (VI), the serial dilutions being made with buffer of the same *p*H and ionic strength as the protein solution.

In general, the amount of protein precipitated in each experiment increased to a maximum in the second or third—occasionally the fourth or fifth—of the eight tubes in the serial dilution. This suggests that the precipitation is due to the formation of a framework, as in the case of serological precipitation, particularly those in which the precipitating antigen is a simple substance[1].

On the assumptions that at *p*H 5·5–5·7 the dyes combine with the proteins as monomeric molecules, and that the haptenic groups interact with separate combining groups of the proteins, the number of combining groups per γ-globulin is calculated to be 44 for compound III and 36 for compound VI. Similarly, a value of 22 was estimated for albumin with compound III.

Further, it was found that at *p*H values from 5·0 to 5·4 at which neither compounds III nor VI produces a precipitate with albumin, the presence of albumin dramatically decreases the amount of precipitation of these compounds and γ-globulin. Apparently the albumin forms soluble complexes with either or both the dye and the γ-globulin.

These results are of interest in connexion with attempts to manufacture antibodies *in vitro*[2], and also with the observation that the reaction of polyhaptenic substances with purified hapten-homologous antibody is considerably different from that of these substances with antiserum[3].

This work was initiated in the laboratory of Prof. Linus Pauling, California Institute of Technology, whom I wish to thank for his assistance. A complete account of the work will be published elsewhere.

## Influence of Temperature and Iron on Hæmoglobin Synthesis by *Daphnia*

*Daphnia*, in common with other branchiopod Crustacea, synthesizes hæmoglobin in response to a deficiency of dissolved oxygen in the surrounding water[1]. The hæmoglobin is in solution in the blood. In poikilothermal animals, chemical processes in the body normally proceed more rapidly at a high external temperature, and we have found that in *Daphnia* hæmoglobin synthesis is quicker in warm water. We wished, in addition, to know whether, at the lower of two temperatures, *Daphnia* would eventually acquire as much hæmoglobin as at the higher temperature (the low oxygen contents of the waters being maintained at the same level) or whether at the higher temperature a greater amount of hæmoglobin would be synthesized. The second alternative proved to be correct. In one experiment with *D. obtusa*, in water containing approximately 1 ml. dissolved oxygen per litre, the hæmoglobin content of the blood increased, in 28 days, five-fold at 17° C. but seven-fold at 28° C. After that there was no further increase. One cause of the greater synthesis at the higher temperature is probably the low oxygen content of the tissues, due to a high metabolic rate.

There are great differences in the iron content of natural fresh waters in which *Daphnia* lives. It has been found to vary between 50 mgm./l. and no iron detectable by dipyridyl (before or after reducing). The question thus arises as to whether the addition of iron salts to water containing little, or no, detectable iron would increase the quantity of hæmoglobin synthesized by *Daphnia* in response to oxygen deficiency. Our work has shown this to be the case. In one experiment, at 20° C., in water with no detectable iron and a low dissolved oxygen content of 0·9 ml./l., the blood hæmoglobin increased seven-fold in sixteen days (deriving its iron no doubt from algal food) and then remained steady for a further twelve days; whereas in similar water, to which 4 mgm./l. iron was added every other day, the increase in sixteen days was between nine-fold and ten-fold, with subsequent maintenance of this level for twelve days.

It was found that ferrous salts are more effective than ferric salts in augmenting hæmoglobin synthesis. This is curious for the following reason. A hæmochromogen is present in the gut lumen of *Daphnia*[2]. At the low oxygen content of the outside water necessary for hæmoglobin synthesis by *Daphnia*, this hæmochromogen can be seen with a spectroscope to be in the reduced state, the α-absorption band showing clearly. Now, the redox potential for the reduction of various hæmochromogens is known to be well below that at which the ferric ion is reduced to the ferrous state[3]. It is thus probable that in the gut lumen of *Daphnia* iron is in the ferrous state, even if swallowed as a ferric salt. The explanation of the greater effect of ferrous salts in increasing hæmoglobin synthesis seems to be as follows. The ferric salt added to the experimental water is gradually converted to ferric hydroxide and precipitated. The ferrous salt is also converted to ferric hydroxide, but in a more finely-divided state which remains longer in suspension, and is thus available to *Daphnia* for a longer time.

A full account of these results will appear in the *Proceedings of the Royal Society*.

## Role of Choline in the Oxidation of Fatty Acids by the Isolated Liver

THE lipotropic effect of choline has been interpreted most generally by assuming that fatty acids are carried out of the liver in the form of plasma phospholipides. However, the role of these compounds in the transport of fatty acids has been questioned[1]. The results presented here strongly suggest that choline acts by enhancing the oxidation of fatty acids in the liver.

In each experiment, slices or homogenates were prepared simultaneously from the liver of rats previously maintained on different diets, namely, (*A*) a choline-deficient diet (diet 26, containing 5 per cent casein[2] with added guanidoacetic acid 1 per cent), (*B*) a choline-supplemented diet (diet 26, with added choline-hydrochloride 0·4 per cent), or (*C*) a stock diet. In most experiments one or two animals received also 0·1 millimole of choline-hydrochloride, given in two intramuscular injections, 1·5 and 0·5 hr. before the rats were killed. The slices or homogenates were incubated with 1-$^{14}$C sodium stearate (obtained from U.S. Testing Co., Hoboken, N.J., on allocation from the U.S. Atomic Energy Commission) in a medium of Ringer-phosphate without calcium or magnesium[3]. Control flasks containing the same amounts of materials were kept at 100° for 10 min. before the addition of the isotopic stearate and then incubated. The carbon dioxide produced during the incubation was trapped in sodium hydroxide, precipitated as barium carbonate, and its radioactivity determined with a *Q* gas-flow counter. Total lipides, lipide phosphorus, and total nitrogen were determined on separate samples of the liver.

CARBON DIOXIDE PRODUCTION FROM 1-$^{14}$C-STEARATE

| Exper No. (and days on diet) | Preparation | Diet | Liver fat* (mgm./gm.) | Carbon-14 dioxide (counts per min.)† | |
|---|---|---|---|---|---|
| | | | | 1 gm moist tissue | Whole liver of a 100-gm. rat |
| 11 (0) | Slices‡ | Choline-def. | 83 | 1,985 | 8,340 |

| 15 (28) | Homogenate‖ | Choline-def. | 166 | 278 | 1,520 |
| | | Choline-def.†† | 152 | 1,404 | 7,750 |

* Liver fat = total lipides, less total phospholipides (lipide phosphorus × 25)

† Each value is the average of 3–4 determinations on separate flasks, and has been corrected for the radioactivity in the control flasks.

‡ Liver slices (0·5–0·7 gm.) in Ringer-phosphate without calcium or magnesium (pH 7·4), incubated in air for 3 hr. at 37° (Warburg water-bath). Additions: 1-$^{14}$C sodium stearate (1–1·5 $\mu M$, 2–3 × 10$^{5}$ c.p.m.), penicillin and streptomycin (3 mgm. each). Total volume: 6–7 ml.

†† Rats injected with choline-hydrochloride (0·05 m$M$), 1·5 hr. and 0·5 hr. before death.

‖ 0·8 liver homogenized (1 : 5) in Ringer-phosphate without calcium or magnesium (pH 7·4). Additions: 1-$^{14}$C stearate (1 micromole, 2·0 × 10$^{5}$ c.p.m.), adenosine triphosphate (2 × 10$^{-3}$ m$M$), penicillin and streptomycin 3 mgm. each. Total volume: 6·5 ml.; 3 hr. incubation in air.

The results of a few representative experiments are reported in the accompanying table. Liver slices from rats on choline-deficient diet produced less carbon-14 dioxide than those from rats on the stock diet. Supplementation of the deficient diet with choline raised the values of the isotopic carbon dioxide. Differences in the amounts of isotopic acetoacetate paralleled those described for the production of carbon-14 dioxide.

The most marked and consistent increases were observed in the livers of rats injected with choline shortly before death. It may be suggested that a high rate of production of carbon-14 dioxide by the isolated tissue is dependent upon a certain level of choline (or of a choline derivative) at the beginning of the experiment, and that ingestion of a diet containing choline does not maintain at all times such optimum level in the liver cells, possibly because of a rapid destruction of the active factor. This would be consistent with the well-known rapid disappearance of choline introduced in the body. The possibility should perhaps be considered that, in the liver of choline-deficient animals, the isotopic stearate might have been diluted by the large amounts of fat accumulating in the tissue, with a consequent lowering of the specific activity of the stearate at the site of its oxidation. However, the lack of a quantitative inverse relationship between the fat content of the liver and the production of carbon-14 dioxide is not in favour of such a possibility. Furthermore, from the similarity of the results obtained in the experiments with slices and homogenates, it would appear that the action of choline cannot be explained simply by an increase in permeability of the cell membrane, and more probably consists of a stimulation of fatty acid oxidation in the isolated liver. Since *in vitro* addition of choline (in concentrations 0·003–0·015 $M$) was not effective, it is suggested that the active factor is not choline, but some substance formed from choline *in vivo*[4].

This work was carried out under contract *AT*(40–1)–288 with the United States Atomic Energy Commission. Technical assistance was given by H. Pollard. The interest and co-operation of Dr. M. A. Swanson are gratefully acknowledged.

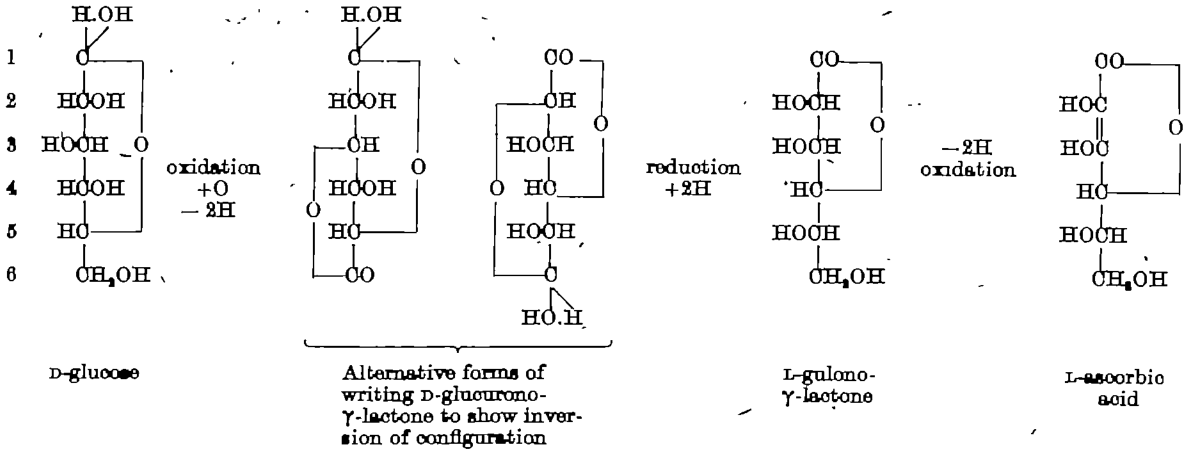
## Synthesis of L-Ascorbic Acid in Plants and Animals

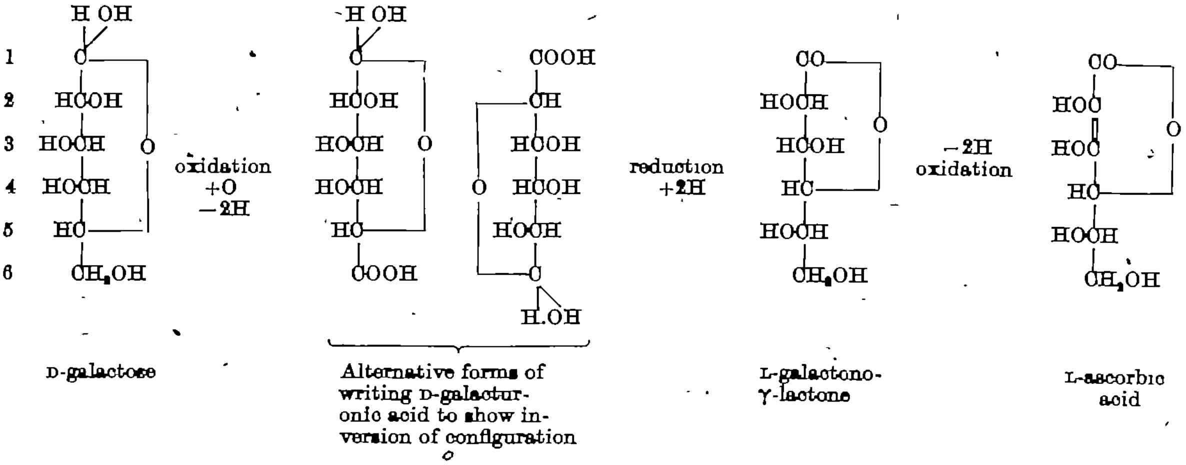
STUDIES in this laboratory have yielded evidence with both plants and animals that the conversion of D-glucose to L-ascorbic acid is by way of D-glucuronic acid and L-gulonic acid (or derivatives), and it seems that D-galactose may also pass to L-ascorbic acid through corresponding intermediates. The overall conversion of sugars (D-glucose, D-fructose and D-mannose) into L-ascorbic acid had, of course, been demonstrated previously, by Ray[1] and others in plants, and by Jackel, Mosbach, Burns and King[2] in animals.

The experimental facts are as follows. The γ-lactones of D-glucuronic acid and L-gulonic acid, when fed to cress seedlings or injected into rats, were found to be transformed into L-ascorbic acid. D-Galacturonic acid methyl ester, and L-galactonic acid γ-lactone behaved similarly. No other sugar acid γ-lactone yielded L-ascorbic acid when tested in the same way, although all the sugar acid γ-lactones, both D- and L-, were examined except those of L-allonic and L-altronic acids. The inactivity of L-idono- and L-talono-γ-lactones was particularly interesting, because these compounds respectively differ from the L-gulono- and L-galactono-γ-lactones solely in the configuration of carbon atom 2.

These facts suggest that two analogous sequences of reactions can take place, as indicated in the accompanying schemes. A fundamental feature of both schemes is the change, at the second step, from the D- to the L-series with inversion of the whole molecule; and it is significant here that Horowitz, Doerschuk and King[3] have just shown that, in the rat, feeding of D-glucose labelled with carbon-14 at position 1 produces L-ascorbic acid labelled only at position 6. It appears that the enzymes catalysing the transformation of the aldonic acid into L-ascorbic acid are specific for an L-configuration of the hydroxyl groups on carbon atoms 2 and 5 (referred to L-ascorbic acid) and for the D-configuration on carbon atom 4.

During the above investigation, we found that D-arabo-ascorbic acid (the configuration of which differs from L-ascorbic acid only at carbon atom 5) was produced from two of the lactones, in the rat from D-mannono-γ-lactone *only* and in cress seedlings from D-altrono-γ-lactone *only*, and here the configuration of the hydroxyl group on carbon atom 3 was specific. We have not found, however, that the corresponding difference between the L-gulonic and L-galactonic acid γ-lactones has any obvious influence on the synthesis of L-ascorbic acid in the plant or





the animal. There is thus no indication which of our postulated reaction sequences is the more important.

Other mechanisms whereby hexoses might be transformed into L-ascorbic acid, involving L-glyceraldehyde, L-sorbose, D-sorbitol and D-gluconic acid, have not been found in cress seedlings or in the rat.

This work will be published in detail elsewhere.

## Light Pulses from the Night Sky associated with Cosmic Rays

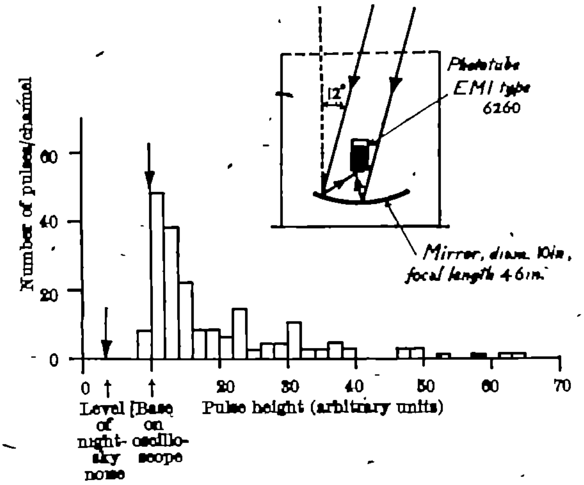
In 1948, Blackett[1] suggested that a contribution approximately $10^{-4}$ of the mean light of the night-sky might be expected from Čerenkov radiation[2] produced in the atmosphere by the cosmic radiation. The purpose of this communication is to report the results of some preliminary experiments we have made using a photomultiplier, which revealed the presence of light-pulses of short duration correlated with cosmic radiation.

A photomultiplier was mounted with its cathode at the focus of a parabolic mirror (see diagram, inset), the field of view of this 'telescope' being approximately ± 12° from the zenith. The output of the phototube was connected to an amplifier with equal differentiation and integration time-constants of 0·032 μsec. The apparatus was mounted in a field adjacent to this establishment at the centre of a square array of sixteen Geiger–Muller counters (each of area 200 $cm.^2$; the sides of the entire array were 180 metres) designed by Cranshaw[3] for studies of extensive air-showers. The results obtained were as follows.

(*a*) On the night of September 25–26, the pulses were first observed visually on the oscilloscope and were seen to be several times the mean height of the noise pulses due to the general night-sky illumination. Photographs of the pulses were taken and a pulse height distribution plotted (see graph). With the bias arbitrarily set at three times the night-sky noise, 97 pulses were recorded in 100 min.

Artificial night-sky noise was then produced by means of a small lamp inside a lid placed over the telescope. In 60 min., no noise build-up pulses were observed at the same bias and gain conditions.

(*b*) Three-fold coincidence pulses corresponding to showers detected by the extensive shower array were used to trigger the time-base of the oscilloscope, and the light pulses (if any) displayed on the *Y*-plates.



In nineteen such showers there was no evidence of any having associated light pulses.

(c) On the night of October 14–15, we decided to trigger the oscilloscope from the light pulses (again selected to be greater than three times night-sky noise) and display the pulses from all the sixteen single counters from the extensive shower array on the Y-plates. Out of fifty time-bases triggered (in 58 min.), eighteen had single Geiger–Müller pulses at the same point on the time-base; two had a coincidence between two Geiger–Müller tubes, one corresponding to three Geiger–Müller tubes and one to four Geiger–Müller tubes. This rate of observing Geiger–Müller pulses on the time-bases associated with light-pulses (when the association is to within 3 μsec.) is approximately a thousand times the accidental coincidence-rate. Moreover, the fact that all the Geiger–Müller pulses occur at the same point on the time-base and correspond in some instances to more than one counter being discharged strengthens the correlation between them and the light.

(d) On October 22, a night of complete cloud, when the cloud-base was known to be between 4,000 and 9,000 ft., pulses at about half the rate were observed under the same conditions of gain and bias.

The conclusions are: (i) a large fraction of the light pulses observed are directly correlated with the cosmic radiations; (ii) none of the light pulses may be attributed to spurious effects, for example, high-tension breakdown, electromagnetic pick-up or noise pile-up; (iii) from the steepness of the front of the electrical pulse, it is deduced that the duration of the light pulses is less than approximately 0·2 μsec.

The negative result of experiment (b), in which we observed no light pulses on the nineteen time-bases triggered from the showers, may be accounted for by the smaller angle of acceptance for the light by the telescope than for showers by the Geiger array.

Some of the light pulses observed may result from relatively soft showers high in the atmosphere from which only a few particles survive at sea-level. There is no evidence in the experiments carried out so far to show that the light is, in fact, Čerenkov radiation rather than light produced by ionization. A series of experiments is planned to investigate the exact nature of the phenomenon.

The above experiments were undertaken following a discussion with Prof. P. M. S. Blackett, to whom we are grateful for his continued interest. We wish to thank Mr. W. J. Whitehouse and Dr. E. Bretscher for their encouragement, and Dr. T. E. Cranshaw for the use of the extensive shower array.

## Determinations of Size of Particles with the Electron Microscope

A method recently reported by Timbrell[1] for the determination of particle-size with the light microscope has been applied with slight modification to size-determinations of textile-bonding agents with the electron microscope. These materials are dispersions of spherical polymer particles having sizes in the range 0–0·2 μ. The normal method of size determination involves measurements on photographic plates obtained at known magnification using a transparent graticule. This method, which is tedious, may be subject to errors due to fatigue of the operator; and the method described has been found much more rapid and reliable.

The photographs of the dispersion are obtained in the usual way with the electron microscope, and the plates are trimmed with a glass cutter so that they can be placed in the holder of an ordinary slide projector. The projected beam is intercepted and deviated on to a screen by a front-aluminized glass mirror which can be oscillated about a vertical axis. Size discrimination can then be made as in Timbrell's method, by the number of overlapping areas present on the screen, each representing a particle with a diameter larger than the amplitude of the oscillation. All the determinations made to date with the instrument have been obtained by counting overlapping areas for various settings of the amplitude control, thus giving the cumulative size-distribution curves.

It has been found advantageous to increase the visual effect of an overlap area by introducing a colour contrast in the following way. A circular sheet of 'Perspex' was dyed in two operations so that one half was red and the other half green. This was then

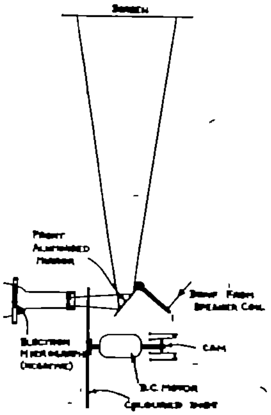

Fig. 1

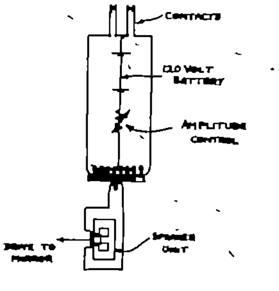

Fig. 2

mounted on the shaft of a small D.C. motor and placed in front of the projector. By rotating the disk in synchronism with the oscillation of the mirror, it could be arranged that the image of a particle at one end of its travel was red and at the other end green. When overlaps occurred they were formed by the additive combination of red and green light, and were yellow in colour and of a high visibility.

The synchronization of the motor and mirror was achieved by means of a rotary switch fastened to the motor spindle, which interrupted the current through the primary winding of a step-down transformer, the secondary winding of which was used to drive a small speaker-unit connected to the mirror. The power for the mirror drive was obtained from a 120-V. dry battery, and with this arrangement the amplitude of oscillation, which was controlled by a small rheostat in series with the battery, was independent of speed of motor over the range determined by fluctuations of the supply voltage. The rotary switch generated a square wave so that the mirror spent the greater part of the time at the ends of its travel. The definition was further improved by blacking out a sector of the 'Perspex' disk corresponding to the region of the oscillation cycle in which the mirror was moved.

The amplitude of oscillation for any setting of the rheostat was easily determined by measuring the movement of grains on the photographic plate, which when related to the scale on the plate gave the amplitude directly in microns. The optical arrangement used is shown in Fig. 1, and the circuit in Fig. 2.

If the rotating disk was omitted, the only unmodulated regions of illumination on the screen would be the overlaps (assuming the projector lamp to be supplied with direct current), and this property might be used as a basis for counting such areas automatically. This development is at present being investigated.

## Coincidence and Overlap Errors in the Automatic Counting and Sizing of Particles

IN the automatic counting and sizing of a population of particles on a glass slide or a photograph[1] errors arise when adjacent particles are closer than the limit of resolution of the counting apparatus or when they overlap along the scanning track: in both cases the two particles are counted as a single particle of larger size. If the centres of the particles are randomly distributed along the scanning track and the number counted is large, the probability that two successive centres will be less than a distance $Z$ apart is

$$1 - \exp(-\alpha Z), \qquad (1)$$

where $\alpha$ is the mean number of particles per unit length of track. If the order in which particles are encountered along the scanning track is random with respect to size and their projections on the plane of the track are circular, the probability that the sum of the radii of two successive countable particles is between $u$ and $u + \mathrm{d}u$ is:

$$Q(u)\mathrm{d}u = 2\,\mathrm{d}u \int_{D_1/2}^{u-D_1/2} P(x)\, P(u-x)\, \mathrm{d}x, \qquad (2)$$

where $P(x)\mathrm{d}x$ is the probability of a particle with radius between $x$ and $x + \mathrm{d}x$, and $D_1$ is the diameter of the smallest particle counted. The condition for resolution of the two particles is $Z > R_0 + u$, where $R_0$ is the limit of resolution of the counting apparatus. The coincidence error is given by the joint probability of (1) and (2), namely,

$$\varepsilon = 2\int_{D_1}^{D_2} \left[ \left\{ (1 - \exp(-\alpha\, \overline{R_0 + u}) \right\} \int_{D_1/2}^{u-D_1/2} P(x)\, P(u-x)\mathrm{d}x \right] \mathrm{d}u, \qquad (3)$$

where $D_2$ is the diameter of the largest particle present. This expression does not allow for coincidences arising from particles that protrude into the scanning track although their centres lie outside it. If necessary, this allowance can be made by adding to $P(x)$ in the analysis the probability of an intercept length $2x$ when the particles are scanned by a line[2], given by the equation:

$$\varphi(2x) = x/(2\bar{r}). \int_{x}^{D_2/2} P(r)\, (r^2 - x^2)^{-1/2}\, .\, \mathrm{d}r.$$

The particle radius $r$ is a variable independent of $x$, and $\bar{r}$ is the mean particle radius.

Result (3) may be applied, for example, to a thermal precipitator sample of an airborne coal-mine dust. $P(x)\mathrm{d}x$, the probability of a particle the projected area of which equals that of a circle of radius between $x$ and $x + \mathrm{d}x$, is approximately $K \exp(-\lambda x)\mathrm{d}x$, where $\int_{D_1/2}^{D_2/2} K \exp(-\lambda x)\mathrm{d}x = 1$, and $D_1$ and $D_2$ lie within the range 0·5–10 microns.

By substitution in (3),

$$\varepsilon = 2\int_{D_1}^{D_2} \left[ \left\{ 1 - \exp(-\alpha\, \overline{R_0 + u}) \right\} \int_{D_1/2}^{u-D_1/2} K^2 \exp(-\lambda u)\mathrm{d}x \right] \mathrm{d}u. \qquad (4)$$

If $\lambda > \alpha$ ($\lambda = 0{\cdot}8$, $\alpha < 0{\cdot}02$ in this case), $D_2$ is much greater than $D_1$ and $\varepsilon > \varepsilon^2/8$, equation (4) simplifies to give:

$$\alpha = \varepsilon/\{2(D_1 + R_0)\}. \qquad (5)$$

The mean number of particle centres per unit length of track, $\alpha$, is also $W\rho$, where $W$ is the track width and $\rho$ the mean number of particles exceeding $D_1$ in diameter per unit area of sample. The number exceeding 0·5 micron in diameter, here written $\rho_0$, is easy to measure, and $\rho = \rho_0 \exp\{-\lambda(2D_1-1)/4\}$. By substituting for $\alpha$ in (5),

$$W = \varepsilon \exp\{\lambda(2D_1 - 1)/4\}/\{2\rho_0(D_1 + R_0)\}.$$

No account has been taken of the irregular shapes of coal-mine dust particles, for which it can be shown that a rough allowance can be made by multiplying $\lambda$

by a factor of 0·8. Optical considerations place a lower limit of 1 micron on $D_1$. Typical values are $\rho_0$ is equal to one particle per 150 square microns, $\lambda$ is 0·8, $R_0$ is 0·5 micron. To confine the coincidence error to 5 per cent of all particles greater than 1 micron, the permissible track width, $W$, is approximately 4·5 microns.

Equation (3) does not make a complete correction for coincidence effects when there are particles present which are smaller than the smallest particles that are to be counted, that is, particles the diameter of which is less than $D_1$. Coincidences in the size-range $D_1/2$–$D_1$ may give a signal above the threshold-level corresponding to $D_1$ and so a spurious count. This effect may be estimated by substituting the appropriate limits of integration in (3). In the case of the coal-mine dust above, these spurious counts would amount to about 0·4 per cent of the total count of particles greater than $D_1$. Similarly, an allowance is required if there are particles greater than $D_2$ present but not counted.

Where it is not necessary to size particles, the signals may be differentiated and a count made of the pulses corresponding to the leading edges of particles. The probability that the radii of two successive particles differ by an amount between $v$ and $v + dv$ is:

$$2\,dv \int_{D_1/2}^{D_2/2 - v} P(x)\,P(x + v)\,dx, \qquad (6)$$

and the condition for their resolution is $Z + v > R_0$. The coincidence error is then given by the joint probability of (1) and (6):

$$\varepsilon = 2\int_{0}^{(D_2 - D_1)/2} \left[ \left\{1 - \exp\left(-\alpha\,\overline{R_0 - v}\right)\right\} \int_{D_1/2}^{D_2/2 - v} P(x)\,P(x + v)\,dx \right] dv. \qquad (7)$$

If (7) is applied to a coal-mine dust sample with the assumptions $\alpha \ll \lambda$, $D_2 \gg D_1$ and $\varepsilon \gg \varepsilon^2/8$, it simplifies to:

$$\alpha = \varepsilon/R_0. \qquad (8)$$

This is the same as the formula obtained by taking (1) as the coincidence error for a random distribution of leading edges with mean interval $1/\alpha$ and the condition $Z > R_0$ for resolution, where $Z$ is now the interval between two successive leading edges. From (8) it is found that, when the coincidence error must be confined to 1 per cent of a count of all particles greater than 1 micron in a coal-mine dust sample, and when an allowance is made for irregular shape of particle, the permissible track width is approximately 5·5 microns.

I wish to thank the Director of the Safety in Mines Research Establishment, and the Ministry of Fuel and Power, for permission to publish this communication.

## Scattering of 56-Mc./s. Radio Waves from the Lower Ionosphere

Incidental to radar studies of the aurora at Saskatoon, Canada (52·1° N., and 106·6° W.), with frequencies of 56 and 106·5 Mc./s., a persistent scatter echo is observed with the lower frequency. This echo arises apparently from the lower ionosphere. As viewed on a conventional range-amplitude display, the scattered signals appear extremely diffuse, but are quite evident on photographs of the display with exposures of a minute or more. A similar type of echo has never been detected at the higher frequency, although both radar units have about the same sensitivity and scan simultaneously the same parts of the sky.

For the 56-Mc./s. equipment, the aerial array-gain relative to a Hertzian dipole is about 16; the direction of maximum radiation is 6° above the horizontal; the peak power of the transmitter pulse, 50 kW.; the duration of the pulse, 16 μsec.; and the receiver sensitivity, $5 \times 10^{-13}$ W. The following statements concerning this echo are based on fairly regular but not continuous operation of the radar units between February 23 and June 6, 1952. Since the primary purpose was to investigate radio echoes from the aurora, the normal operating period covered only the hours of twilight and darkness. However, a sufficient number of runs were made in the daylight hours at least to indicate the diurnal characteristics of the scatter echo.

The echo was strongest during March, decreasing in amplitude during April and May until finally it could only be detected by increasing the power output of the transmitter. It exhibited a minimum value in the late afternoon and increased steadily in amplitude throughout the night. The signal was strong in the morning hours; but the time that it reached a maximum is uncertain. There was no evident relationship between the scatter echoes and the occurrence of either visible aurora or radio echoes from the aurora.

The mean distance of the region from which the echoes arose was invariably about 400 km., extending over a range of about 100 km. for weak signals to about 200 km. for particularly strong ones. The photographic records showed a sharp minimum in the signal amplitude for distances of about 370 km. If this minimum in amplitude corresponds to the first minimum in the radiation pattern of the aerial (about 12° above the horizontal), the scattering region was about 85 km. above the earth's surface. The echoes showed no consistent variation with azimuth of the radar beam, although for periods of several minutes the signals from one direction would be slightly greater than those from other directions.

A similar type of signal has been observed at various times since 1948 by McKinley and Millman (private communication) in connexion with their meteor investigations at a frequency of 33 Mc./s. Their echoes arise apparently in a region directly above their station (Ottawa, Canada) at heights of 80–90 km. If, as seems very likely, the Saskatoon and Ottawa signals have a common origin, it must be one involving scattering rather than reflexion from horizontal stratifications of ionization in the lower ionosphere. It is also likely that these echoes arise in the region responsible for the long-range propagation of very high-frequency signals. If, as has been suggested recently by Booker *et al.*[1], such signals are due to scattering of the radio waves by ionic inhomogeneities, the detection of back-scatter echoes indicates that the scale of the fine structure in the active region is a few metres rather than the hundreds of metres usually attributed to the *E*-region.

Grants and personnel (P. A. F.) from the Defense Research Board of Canada have made this work possible. The radar equipment was made available through the co-operation of the Geophysical Research Directorate, Air Force Cambridge Research Center, Cambridge, Mass.

## A New Method of Light Microscopy

Using annular apertures made in a thin layer of candle soot on a microscope objective lens and corresponding apertures in the condenser, an ordinary microscope can be made very suitable for the study of unstained specimens. There are two different procedures.

To make higher refracting objects appear dark against a light background, it is necessary to find the objective lens surface nearest to the image of the condenser aperture and soot it by short contacts with the flame, until the transparency has diminished by one-half. On a watchmaker's lathe, using a sharp tip of some soft material, a narrow ring-shaped area is freed from soot, the diameter of the ring being greater than half the exit pupil of the objective, that is, at least twice as wide as the phase ring in conventional phase-contrast objectives. When compared with the latter, there are freedom from halo effects, increased resolving power and a pleasing gradation for objects having different refractivity.

Images of greater contrast and with light values similar to those to which we are accustomed in the macroscopic world are achieved if a partly reversed procedure is followed. The sooting is continued until the transparency has decreased to 8–9 per cent, after which the soot is wiped off, except for an area covering the image of the condenser ring aperture. As a result, the background of the microscope image appears in an agreeable sepia tone, often giving the illusion of sky-illuminated objects lying on the sand floor of a shallow sea. Many features which are generally invisible with the normal use of the microscope are rendered visible; for example, influenza virus on red cell ghosts, bacterial flagella, sperm tail pencil, and delicate membranous margins in living thrombocytes (see photographs). Apparently the method can be adapted to ultra-violet microscopy and mirror optics as well.

The theoretical explanation of what occurs in each of the alternative procedures may not be an easy one, since the phase effects in microscopical observation are still incompletely understood[1]. The arrangements described above are the result of some hundreds of trials, in which the conditions were varied one at a time.

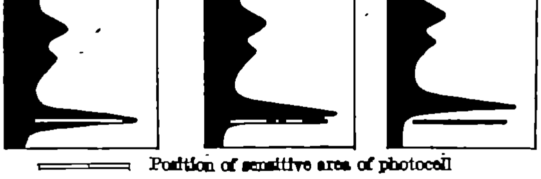
## Photoelectric Control of the Compensator in Electrophoresis

Various types of compensator[1-3] are used in electrophoresis to bring the initial boundaries into view, or to bring a particular boundary into the correct position for isolation of a sample. Manual control of the compensator is quite convenient in these cases. However, it is sometimes necessary to keep a boundary stationary during a long run, either for analytical purposes[4], or in the course of preparative work[5]. The obvious type of automatic control is one based on a photoelectric device; but no such application seems to have been described in the literature.

The main difficulty encountered in applying this principle arose from the very low intensity of the light which reaches the camera screen in the diagonal *Schlieren* optical system[6] of the Tiselius apparatus[1]. This prevented the use of ordinary photoelectric relays. Different ways of increasing the effective light intensity were considered and rejected for various reasons. Instead, it was decided to use a photoconductive cell of the type described by Schwarz[7]. Although the sensitive area is only 0·1 mm. × 10 mm., the sensitivity is very high (10 A./lumen). Moreover, the whole cell is compact (1 cm. diam. × 5 cm.) and can be operated from a small dry battery.

The following arrangement was finally adopted. The cell is situated with its photosensitive area in the focal plane of the camera (see Figs. 1–3), and connected in series with a 4·5-V. dry battery and a 'Cambridge' spot galvanometer, the latter being fitted with a variable shunt. A second Schwarz[7] photocell is held against the scale of the galvanometer, where it is illuminated by the light spot under particular circumstances. It is connected in series with a 13·5-V. dry battery and the coils of a small relay, the contacts of which control the supply of current to the compensator. It is particularly convenient to use the electrolytic type of compensator[5] here. The intermediate galvanometer relay is essential, because the very low light intensity differential between the bright and dark parts of the field ($10^{-7}$ lumens) produces a current of the order of 1–2 μA., quite insufficient to operate a relay directly. The second photocell gives rise to a current of 3 mA., which is ample for the purpose.

The cycle of operations may be described as follows. With the system as shown in Fig. 3 the photocell in the *Schlieren* system produces its maximum current, causing the galvanometer light to fall on the other photocell. The relay is thereby actuated, and prevents the compensator from functioning. The current through the Tiselius apparatus then moves the boundaries until (Fig. 2) the first photocell is partly obscured and the light spot moves away from the second photocell, indirectly bringing the compensator into action. This is usually set to a rate 50–100 per cent greater than that which would, by continuous operation, keep the boundary stationary. Thus the boundary actually moves back while the compensator is in action until the original situation (Fig. 3) is restored, and the cycle recommences. Success is dependent on the stability of the maximum current from the first photocell. A superior arrangement, in which a certain amount of drift is permissible, is when the second photocell is between the positions the light spot occupies when the first photocell is fully illuminated (Fig. 3) or in the dark (Fig. 1). Before the compensator is connected to the photoelectric control the boundary is brought to the appropriate intermediate position (Fig. 2), so that the galvanometer light falls on the second photocell. The system then cycles reliably, the boundary moving a small distance on each side of a mean position. It is necessary to bring the initial boundary to the correct level because, if the system is allowed to start from the extreme position shown in Fig. 1, the spot of light may sometimes swing completely past the second photocell. In order to prevent any failure due to the distortion or obscuring of the peak by condensed moisture it is the practice, particularly under humid conditions, to leave a current of air blowing over the external surfaces of the windows of the electrophoresis bath.



▭ Position of sensitive area of photocell

## A Crystalline Hydrated Magnesium Silicate formed in the Breakdown of a Concrete Sea-wall

During an investigation of a serious breakdown of a concrete sea-wall, a small amount of a finely divided soft white deposit has been found which gives an X-ray diffraction pattern not unlike that of $4CaO.Al_2O_3.13H_2O$. However, the chemical composition of the material, after allowing for 23 per cent impurity of calcium carbonate and 3 per cent of silica, can be expressed ideally as $4MgO.SiO_2.8\cdot5H_2O$. This is thought to be the first reported occurrence of a crystalline hydrated magnesium silicate formed at ordinary temperatures in the breakdown of a cement. Steopoe[1] has given indirect evidence of the formation of such a compound through the action of magnesium hydroxide on silica gel present in cement mortars decomposed by sulphate attack. The material reported on here has probably formed in a manner similar to that discussed by Steopoe. The magnesium hydroxide arises from the breakdown of calcium sulpho-aluminate through the presence of soluble magnesium salts derived from the sea-water[2]. The calcium sulpho-aluminate is, as is well known, a common product of reaction between calcium sulphate solutions and calcium aluminate. Silica gel can be expected to form readily from the poorly crystallized hydrated calcium silicates of the set cement under the decomposition conditions.

The X-ray diffraction pattern of the new material can be indexed to a hexagonal unit cell of spacings $a = 8\cdot95$ A., $c = 8\cdot10$ A. (cf. $a = 8\cdot8$ A., $c = 8\cdot2$ A. for $4CaO.Al_2O_3.13H_2O$ found by Wells, Clarke and McMurdie[3]). The $c$-axis has dropped by 0·16 A. over several years, being originally 8·26 A. No weight is lost on heating from 110° to 160° C., but from here to 1,000° C. the material shows a continuous loss of close on 40 per cent of its air-dry weight. X-ray powder photographs show that the hydrated magnesium silicate, after losing 10·7 per cent structural water (3·1 molecules), is replaced at 340° C. by periclase (MgO) and a hydrated magnesium silicate of lower MgO content than the original material. The structure of the last is stable until about 650° when it, too, is destroyed. At 700° C. the reaction products recrystallize as periclase and forsterite ($2MgO.SiO_2$), together with a little unidentified material. These experiments suggest that the structural formula of the original material can be written as $3Mg(OH)_2.MgSiO_3.5\,5H_2O$.

Further work is proceeding on the properties and synthesis of the new material and its relation to other low-temperature forms of magnesium hydrated silicate, and a more detailed account will be published at a later date.

## 'Parathion' and Ultra-violet Light

Pure 'Parathion' is not at present considered to be an inhibitor of cholinesterase *in vitro*[1-3]. It is probable that those who first reported[4-6] to the contrary were using samples contaminated with one or more of the following: O-S-diethyl *p*-nitrophenyl thiophosphate, diethyl S-*p*-nitrophenyl thiophosphate and diethyl *p*-nitrophenyl phosphate ('Paraoxon'), all of which possess anticholinesterase activity *in vitro*[3].

We have found that when emulsions of 'Parathion' in aqueous salt solutions are exposed to ultra-violet light (wave-length 1850–4000 A.), they develop anticholinesterase activity progressively (Fig. 1,*c*). This activation occurred first at room temperature in emulsions and solutions (Fig. 1,*a* and *b*; Fig. 2) exposed to daylight. It did not occur in the dark (Fig. 1,*d*), or in electric light.

Estimation of the anticholinesterase activity developed has been carried out manometrically by the Warburg method. A homogenate of rat brain, or washed rat erythrocytes, has been used as source of cholinesterase, and 0·03 *M* acetyl-β-methylcholine chloride as substrate. The total volume of the flask contents has been 3·0 ml., and 'Parathion' solutions ($6·9 \times 10^{-5}$ *M*) and emulsions ($3·45 \times 10^{-4}$ *M*) have been sampled at the rate of 1·0 or 0·1 ml. per flask. The cholinesterase and 'Parathion' were incubated for 30 min. before addition of the substrate.

Activation of 'Parathion' in this way occurs in any of the following solvents: 0·85 per cent sodium chloride, *M*/40 sodium bicarbonate, *M*/15 phosphate buffer mixtures over the *p*H range 5·5–7·5, and in an *M*/20 borate buffer mixture, *p*H 8·5 (Fig. 2).

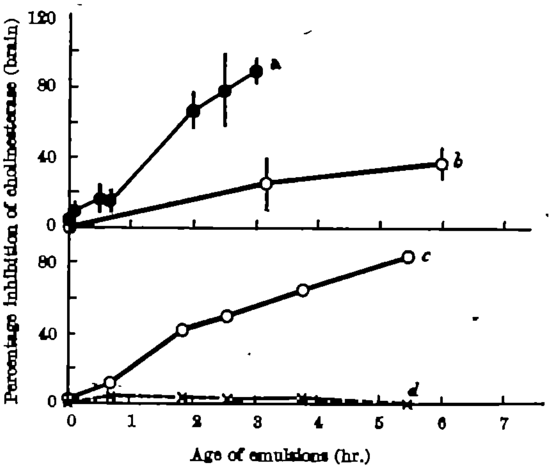

Fig. 1. Influence of light upon the development of anticholinesterase activity by emulsions of 'Parathion' (concentration $3·45 \times 10^{-4}$ *M*) in 0·067 *M* phosphate buffer mixtures, *p*H 6·5. (*a*) and (*b*) Emulsions kept in daylight, sampling 1·0 ml. and 0·1 ml. respectively per Warburg flask. The vertical lines indicate the standard errors of 2–9 observations. Sunlight highly variable (August): room temperature range, 20–26° C. (*c*) Emulsions exposed at a distance of 2 ft. from an ultra-violet lamp. (*d*) Emulsions kept in darkness. Emulsions sampled at the rate of 0·1 ml. per flask. Room temperature, 25° C. ± 1°

The active inhibitor present in irradiated emulsions is destroyed by rat blood (that is, the plasma fraction) at a greater rate than that at which it combines with cholinesterase. For example, a volume of emulsion which caused 75 per cent inhibition of 20 mgm. brain caused no appreciable inhibition of 0·22 ml. whole blood, although these two quantities of enzyme preparations possess approximately equal cholinesterase activities. It is only when this same quantity of brain was completely inhibited that 10 per cent inhibition of blood could be detected.

At least three possibilities exist to account for this development of anticholinesterase activity in 'Parathion' emulsions or solutions exposed to sunlight or artificial ultra-violet radiation under the conditions stated: (1) 'Parathion' itself is being transformed

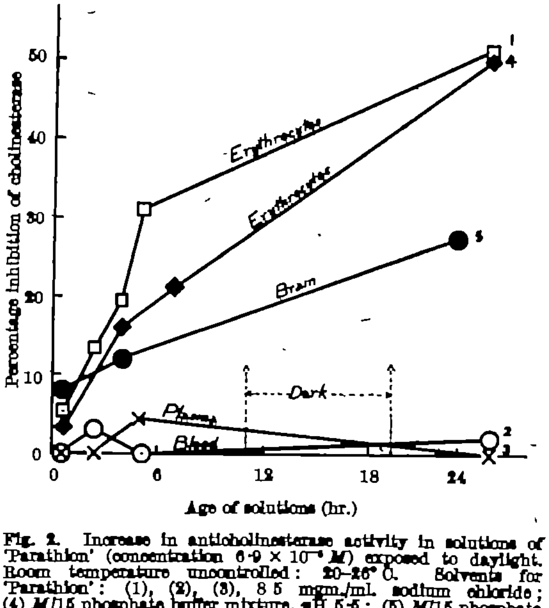

Fig. 2. Increase in anticholinesterase activity in solutions of 'Parathion' (concentration $6·9 \times 10^{-5}$ *M*) exposed to daylight. Room temperature uncontrolled: 20–26° C. Solvents for 'Parathion': (1), (2), (3), 8·5 mgm./ml. sodium chloride; (4) *M*/15 phosphate buffer mixture, *p*H 5·5; (5) *M*/15 phosphate buffer mixture, *p*H 7·5

to an active inhibitor, for example, an active isomer; (2) some impurity is activated to an inhibitor of cholinesterase; (3) some factor which prevents 'Parathion' itself from being inhibitory is being progressively removed from the field of interaction by ultra-violet light.

The first of these possible explanations appears to be the most likely. The transformation of 0·3 per cent of the 'Parathion' present to an anticholinesterase equal in activity to 'Paraoxon' could have accounted for the 50 per cent inhibition found when sampling 0·1 ml. of an emulsion exposed to ultra-violet light for 2½ hr. (see Fig. 1,c).

The small amount of *p*-nitrophenol liberated in the emulsions exposed to ultra-violet light is totally inadequate to account for the inhibitory activity developed.

The mechanism of this transformation is being further investigated in these laboratories.

## Effect of a Copper Supplement to the Rations of Milking Cows

THE prevention of symptoms of swayback in the offspring of ewes grazing on affected pastures in Britain has been shown to be effective when the pregnant ewe receives an additional supply of copper[1]. Sufficient copper for the proper metabolism of nervous tissue in the young animal appears to be provided if a single dose of copper is administered to the mother ewe within an hour or two of the birth of its lamb[2].

The widespread appearance of swayback in lambs on farms in the west of Scotland during the war years, following the application of lime to the grazings of the pregnant ewes, raised the question of the effect of copper on the production of other farm animals. Cows are not known to produce swayback-affected offspring, but it appeared possible that the conditioned deficiency of copper in animals grazing swayback pasture might cause a reduction in the butterfat production of lactating cows.

Cunningham[3] has already shown that dairy cows grazing on the peat lands of New Zealand, where copper-deficiency symptoms appear in the lambs of many sheep flocks, produce a larger amount of butterfat when their ration contains extra copper. Before treatment the butterfat production of the herds was disappointingly low.

The problem of copper deficiency affecting dairy cows has not been examined in Great Britain. As a preliminary, it was decided to determine the effect of copper on the butterfat production of cows in west of Scotland herds during the winter period of stall feeding.

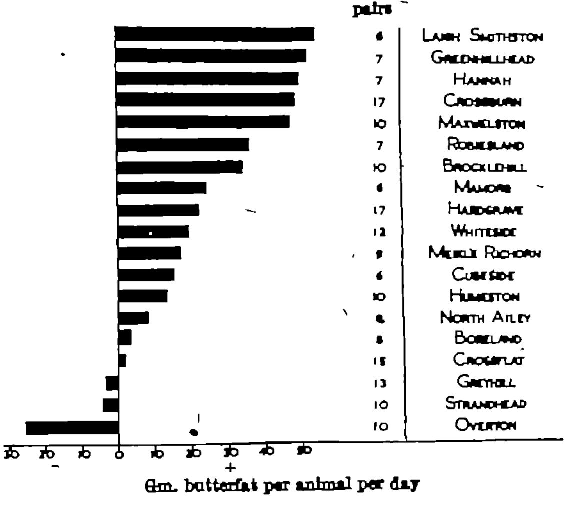
Milk recorders trained by the Scottish Milk Records Association at the West of Scotland Agricultural College determine the yield and the fat content of the milk produced by each lactating animal in the herds of all the members on at least one day during each month of the year. The results obtained by the recorders have been used in this investigation, which was conducted in nineteen different herds in nine counties in the south and west of Scotland.

In each herd two groups of animals were drawn up according to: (1) month of calving, (2) daily yield of milk, and (3) fat yield during the previous lactation. Two tests of the new lactation were regarded as minimal before an animal was put on experiment. Animals nearing the end of their lactation—all on experiment had calved less than eight months previously—were rejected if the yield of fat had dropped to less than 150 gm. of butterfat per day. One group was given supplementary copper, and the other served as control. To the production ration of each animal in the treated group one teaspoonful copper sulphate (10 gm. $CuSO_4.5H_2O$) was added. The inclusion of the full supplement of 10 gm. of the salt in less than a dairy scoopful of the meals (about 3½ lb.) was found to lead on many occasions to refusal of food. In such cases it was found necessary to administer the salt supplement in two doses (5 gm. per feed).

Addition of the supplement in the manner described to the rations of the experimental animals was made within one week of the visit of the recorder. In one herd—Crossburn—the addition of copper sulphate to the meal was delayed as late as the afternoon before the recorder's visit, that is, about 25 hr. before the recorder commenced his measurement of the yield of milk and of fat produced by the cows. Even when the supplement was fed at this late period the response elicited was most marked[4].

After the recorder had entered the results of the tests in the herd milk record book, the experimental results for the animals in the nineteen herds were examined statistically (see histogram). The observations were examined at Rothamsted Experimental Station, with the following result: weighted mean increase (gm.) butterfat per cow per day, 20·1; standard error, 5·22 (18 d.f.).

The treatment has, therefore, a real effect, although apparently not large enough to be detected on most single farms. The standard error is calculated from $SW(y - \bar{y}_w)^2$, where $W$ is the number of pairs at a farm and is appropriate if the weights are inversely proportional to the within farm variances.



Gm. butterfat per animal per day

The results show that a significant increase in butterfat production has been obtained when additional copper is fed in the manner described to herds selected at random in the west of Scotland.

## Incidence of Meiosis in the Life-cycle of *Halidrys siliquosa* Lyngb.

SEAWEEDS belonging to the Fucales are diploid, and the reduction division has been shown to occur during the first nuclear divisions in both oogonia and antheridia[1–3].

During a recent investigation of the Fucales on the Northumbrian coast, we have found eight chromosomes in the vegetative cells of plants of *Halidrys siliquosa* Lyngb. The same number of chromosomes is present at both the first and second divisions in both oogonia and antheridia. This shows that in *Halidrys siliquosa* meiosis does not take place at the same stage of development as reported for other members of the Fucales. A detailed account of the cytology of this species will be published at a later date.

## Embryology of the Emperor Penguin (*Aptenodytes forsteri*)

E. A. WILSON[1] wrote in 1907, "The possibility that we have in the Emperor penguin the nearest approach to a primitive form not only of a penguin but of a bird, makes the future working out of its embryology a matter of the greatest possible importance". With this aim in mind he set out on June 27, 1911, with Bowers and Cherry-Garrard on a terrible journey[2] in the antarctic winter, during which three embryos were obtained from the Cape Crozier rookery on July 20. These specimens were described by Parsons[3], who considered that the smallest one corresponded to a chick embryo of ten days incubation, whereas the two larger specimens corresponded to chick embryos of thirteen days incubation.

It was not until 1949 that Stonehouse[4] collected a series of Emperor penguin embryos from a rookery fifty miles from one of the bases of the Falkland Islands Dependencies Survey. As a result of this expedition we now possess a new series of sixteen embryos collected between June and August and extending from the primitive streak stage to hatching. All the embryos, with one exception, are in an excellent state of preservation. The poorly preserved specimen was frozen before fixation. The embryos have been compared with and classified according to the normal stages of development in the chick[5]. The smallest nine specimens which were younger than those brought back by Wilson have been sectioned serially and confirm the observations made by Parsons[6] on the Gentoo penguin (*Pygoscelis papua*) and the Ring penguin (*Pygoscelis antarctica*). However, comparison of the development of the external form of the Emperor penguin with that of the chick and with that of other penguins already described, namely, Gentoo and Ring penguins by Parsons[6] and Gentoo and Adelie penguins (*Pygoscelis adelia*) by Waterston and Geddes[7], reveals a fact not yet recorded and worthy of note. In the earlier embryos the head region is relatively smaller, the neck and tail regions relatively longer, and the curvatures less well marked in penguin than in chick embryos. These features are more marked in Emperor penguin embryos and result in early penguin embryos resembling early reptilian embryos more closely than do early chick embryos.

| Serial No. | Date of collection | Corresponding stage in chick | Incubation period in chick | Greatest length of curved embryo | Length from beak or maxillary process to tail |

All measurements taken after fixation

It should be pointed out that the embryos collected on June 26 and July 6, 1949, have reached a stage of development similar to that reached by Wilson's largest specimens. This observation seems to confirm the ones made by Stonehouse[4] on measurements of hatched chicks by which he concluded that the chicks of the rookery at Cape Crozier were hatched about three weeks after the ones from the rookery from which the present series was obtained. A detailed description of the embryos is being written for publication in the near future in the Falkland Islands Dependencies Survey Scientific Reports.

# FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

## Monday, February 23

UNIVERSITY OF LONDON (in the Physiology Theatre, University College, Gower Street, London, W.C.1), at 4.45 p.m.—Prof. Jean Roche (Paris): "Comparative Biochemistry of Iodoproteins".*

BRITISH SOCIETY FOR THE HISTORY OF SCIENCE (in the Lecture Room, Science Museum, Exhibition Road, London, S.W.7), at 5.30 p.m.—Mr. J. A. Chaldecott: "The Zograscope, a Forgotten Name in Optics"; Dr. H. Heywood: "A Brief Description of 18th Century Scientific Instruments recently discovered at Longleat, the Home of the Marquess of Bath".

UNIVERSITY OF LONDON (at Birkbeck College, Malet Street, London, W.C.1), at 5.30 p.m.—Prof. P. Fallot (Paris): "The Tectonics of North Africa".* (Further Lectures on February 24 and 27.)

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W.C.2), at 6 p.m.—Mr. G. Anthony Gardner: "The Safety Factor in Construction", 1. (Cantor Lectures.) (Further Lecture, by Prof. F. C. Thompson, on March 2.)

ROYAL GEOGRAPHICAL SOCIETY (at 1 Kensington Gore, London, S.W.7), at 8.15 p.m.—Dr. S. M. Manton, F.R.S.: "Progress of Soviet Planning in Central Asia".

## Tuesday, February 24

UNIVERSITY OF LONDON (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 1.15 p.m.—Dr. G. H. Brown: "Is there a Philosophy of Science?"*

INSTITUTION OF BRITISH AGRICULTURAL ENGINEERS (at the Institution of Electrical Engineers, Savoy Place, Victoria Embankment, London, W.C.2), at 2.15 p.m.—Mr. W. H. Cashmore: "Recent and Present Work at the N.I.A.E.".

CHADWICK PUBLIC LECTURE (at the Royal Society of Tropical Medicine and Hygiene, 26 Portland Place, London, W.1), at 2.30 p.m.—Dr. Georges Decharneux: "Industrial Medicine and Hygiene in Belgium".*

ROYAL SOCIETY OF ARTS, COMMONWEALTH SECTION (at John Adam Street, Adelphi, London, W.C.2), at 5.15 p.m.—Mr. K. R. S. Morris: "Tsetse Fly Control".

BRITISH POSTGRADUATE MEDICAL FEDERATION (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 5.30 p.m.—Dr. P. L. Mollison: "The Life-Span of Red Cells" ("The Scientific Basis of Medicine", 15).*

SOCIETY OF CHEMICAL INDUSTRY, CHEMICAL ENGINEERING GROUP (joint meeting with the PLASTICS AND POLYMER GROUP, at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 6.30 p.m.—Mr. H. K. Earp, Mr. S. Shapiro and Mr. A. H. Wiggs: "Resin Cements in Chemical Engineering"; Mr. V. Evans: "Corrosion-Resisting Properties of some Synthetic Resin Cements".

SOCIETY OF INSTRUMENT TECHNOLOGY (at Manson House, 26 Portland Place, London, W.1), at 6.30 p.m.—Mr. D. T. Germain-Jones: "Geophysical Prospecting for Oil".

## Wednesday, February 25

ROYAL SOCIETY OF MEDICINE, ENDOCRINOLOGY SECTION (joint meeting with the SOCIETY FOR ENDOCRINOLOGY, at 1 Wimpole Street, London, W.1), at 10 a.m.—Symposium on "Thyroid Gland".

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W.C.2), at 2.30 p.m.—Mr. E. H. Browne: "Improving Coal Production" (Cadman Memorial Lecture).

GEOLOGICAL SOCIETY OF LONDON (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Scientific Papers.

ROYAL STATISTICAL SOCIETY (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 5.15 p.m.—Mr. G. F. Peaker: "A Sampling Design used by the Ministry of Education".

ILLUMINATING ENGINEERING SOCIETY (at the Lighting Service Bureau, 2 Savoy Hill, London, W.C.2), at 6 p.m.—Discussion on "The Lighting of Pedestrian Crossings".

## Thursday, February 26

ROYAL SOCIETY (at Burlington House, Piccadilly, London, W.1), at 10.30 a.m.—Discussion on "The Floor of the Atlantic Ocean" (to be opened by Dr. E. C. Bullard, F.R.S.).

ROYAL INSTITUTE OF PHILOSOPHY (in the Assembly Hall, Institute of Education, Malet Street, London, W.C.1), at 5.45 p.m.—Viscount Samuel: "Man's Ideas about the Universe".

ROYAL AERONAUTICAL SOCIETY (at the Institution of Mechanical Engineers, Storey's Gate, St. James's Park, London, S.W.1), at 6 p.m.—Mr. H. J. Pollard: "New Materials and Methods for Aircraft Structure".

SOCIETY OF CHEMICAL INDUSTRY, MICROBIOLOGY GROUP (joint meeting with the FOOD GROUP, at the Institution of Electrical Engineers, Savoy Place, Victoria Embankment, London, W.C.2), at 6.15 p.m.—"Pathogenic Organisms in Food" (Dr. C. Cockburn: "Epidemiology of Food Poisoning"; Dr. R. E. O. Williams: "Staphylococci and other Gram Positive Cocci"; Dr. Joan Taylor: "Enterobacteriaceae").

SOCIETY OF CHEMICAL INDUSTRY, LONDON SECTION (joint meeting with the LONDON SECTION of the ROYAL INSTITUTE OF CHEMISTRY, at the South-East Essex Technical College, Longbridge Road, Dagenham), at 7 p.m.—Dr. K. G. A. Pankhurst: "The Physics and Chemistry of Detergent Solutions".

CHEMICAL SOCIETY (at the Royal Institution, 21 Albemarle Street, London, W.1), at 7.30 p.m.—Prof. A. Tiselius: "Some Applications of the Separation of Large Molecules and Colloidal Particles" (Centenary Lecture).

SOCIETY FOR VISITING SCIENTISTS (at 5 Old Burlington Street, London, W.1), at 7.30 p.m.—Discussion on "The Chemistry and Interrelationship of Endocrine Systems and their Psychological Effects" (Chairman: Dr. A. S. Parkes, F.R.S.: Speakers: Prof. F. G. Young, F.R.S., Prof. Jean Roche, Prof. G. W. Harris).

## Friday, February 27

ASSOCIATION OF APPLIED BIOLOGISTS (in the Mining Lecture Theatre, Imperial College of Science and Technology, Prince Consort Road, London, S.W.7), at 10.30 a.m.—"The Assessment of Plant Pests and Diseases".

ROYAL ASTRONOMICAL SOCIETY (at Burlington House, Piccadilly, London, W.1), at 4.15 p.m.—Geophysical Discussion on "Ocean Swell and Microseisms" (Chairman: Dr. G. E. R. Deacon; Speakers: Dr. M. S. Longuet-Higgins, Mr. J. Darbyshire, Prof. Maurice Ewing).

NORTH-EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (at the Mining Institute, Newcastle-upon-Tyne), at 6.15 p.m.—Dr. J. F. Allan: "Wake Studies of Plane Surfaces".

BRITISH ASSOCIATION OF CHEMISTS (in the West Hall, Royal Society of Medicine, 1 Wimpole Street, London, W.1), at 6.30 p.m.—Dr. Herbert Levinstein: "Our Changing Chemical Industries—an Appraisement" (Hinchley Medal Address).

TELEVISION SOCIETY (at the Cinematograph Exhibitors' Association, 164 Shaftesbury Avenue, London, W.C.2), at 7 p.m.—Mr. D. McMullan: "The Scanning Electron Microscope".

## Saturday, February 28

BRITISH PSYCHOLOGICAL SOCIETY, EDUCATION SECTION (in Room 151, Institute of Education, Malet Street, London, W.C.1), at 2.30 p.m.—Prof. P. E. Vernon: "The Personality of the Teacher" (Chairman's Address).

# APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

ASSISTANT ADVISORY OFFICER IN BACTERIOLOGY (with a degree in science or agriculture with bacteriology)—The Secretary, North of Scotland College of Agriculture, 41½ Union Street, Aberdeen (February 27).

ASSISTANT PHYSICIST (with a good honours degree in physics) to work on the 15 MeV. Linear Accelerator—The Clerk to the Governors, St. Bartholomew's Hospital, London, E.C.1, endorsed 'Physicist' (February 28).

DIRECTORSHIP OF STUDIES IN MEDICINE (combined with a Lectureship (or Assistant Lectureship) in a relevant subject, preferably physiology or anatomy)—The College Secretary, Girton College, Cambridge (February 28).

GENERAL ASSISTANT ENGINEER (Efficiency and Testing) at Divisional headquarters—The Divisional Secretary, British Electricity Authority, London Division, Generation House, Great Portland Street, London, W.1 (February 28).

HEAD OF THE CIVIL AND MECHANICAL ENGINEERING DEPARTMENT—The Clerk to the Governors, Woolwich Polytechnic, Woolwich, London, S.E.18 (February 28).

LECTURER (Grade II or III) IN THE DEPARTMENT OF MECHANICAL ENGINEERING—The Registrar, The University, Bristol 8 (February 28).

MATHEMATICIAN at a Ministry of Supply Research Establishment near Sevenoaks, to work in research team on advanced problems in fluid mechanics or on application of high speed electronic computers to mathematical research—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting A.20/53A (February 28).

PHYSICIST with experience of X-ray diffraction, at a Ministry of Supply establishment at Aldermaston—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting A.21/53A (February 28).

RESEARCH OFFICER (Senior Scientific Officer grade) (with membership diploma of the R.C.V.S. and a university degree, preferably in veterinary science)—The Secretary, Research Institute (Animal Virus Diseases), Pirbright, Surrey (February 28).

SCIENTIST, Grade II (with an honours degree in science or equivalent) in the No. 4 (Burnley) Area—The Divisional Establishment Officer, National Coal Board, North-Western Division, 40 Portland Street, Manchester 1 (February 28).

LECTURER IN MECHANICAL ENGINEERING—The Registrar, Queen Mary College, Mile End Road, London, E.1 (March 2).

DEPUTY WORKS ENGINEER FOR ATOMIC ENERGY factory at Sellafield, for maintenance of nuclear piles and associated chemical plant with particular responsibility for steam, water and electricity supplies, workshops and instrumentation—The Ministry of Supply, Division of Atomic Energy (Production), Risley, Warrington, Lancs, quoting Ref. 423.

LECTURER (with an honours degree in electrical engineering, and practical experience in the field concerned) IN ELECTRICAL ENGINEERING concerned either with the application of automatic control systems to electrical machines or with electrical power system engineering—The Head of the Electrical Engineering Department, City and Guilds College, South Kensington, London, S.W.7.

MECHANICAL AND ELECTRICAL ENGINEERS for design, operation and maintenance of ground mechanical and electrical works services on R.A.F. and Civil Aviation Stations at home and overseas—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting D.290/52A.

MECHANICAL ENGINEER IN THE PUBLIC WORKS DEPARTMENT, Sudan—The Sudan Agent in London, Sudan House, Cleveland Row, London, S.W.1, quoting 'M/Engineer 1824'.

METALLURGIST (Scientific Officer grade) at the Ministry of Supply London headquarters, to assist in research and development on metallic materials for aircraft construction, etc.—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting F.33/53A.

# IMPACT OF TECHNOLOGY ON SOCIETY

THOSE familiar with Mr. Lewis Mumford's earlier works will find little that is new in the six Bamford Lectures which, originally delivered at Columbia University, have now been published under the title "Art and Technics"*. Into this little volume, however, he has distilled the quintessence of that major undertaking to which he set his hand in "Technics and Civilisation" in 1934 and only completed last year in a fourth volume, "The Conduct of Life". In doing so, he has discarded the jargon and neo-dramatization of some of the larger books, and his thought and argument flow in sparkling manner, refreshing and stimulating. His theme, the manner in which man must come to terms with his environment, is expounded with a freshness and vivacity as if he had never handled it before; and, when he deals further shrewd blows against the weaknesses or abuses that he has already attacked, there is no hint of repetition or staleness in his words.

Readers of "The Culture of Cities" will recall, for example, Mr. Mumford's passionate plea in that volume for imaginative thinking about the whole purpose of design, and for a determined effort to think out and discover appropriate forms of expression for the new materials and powers now at our disposal. That forthright condemnation of our practice of clinging to obsolete methods and of attempting to force new material into the forms used for earlier products and other purposes is matched in this volume by two further attacks: in one, his lecture on "From Handicraft to Machine Art", Mr. Mumford castigates purposeless change in the machine; and in the other, when discussing symbols and function in architecture, he condemns the abuse of the doctrine that form follows function. The meaningless annual re-stylings of the less essential parts of a motor-car, he points out, largely nullify advances in technical efficiency which would enable manufacturers to lengthen the life and lower the cost of their models. Instead, he writes: ". . . You know that the canons of conspicuous waste, dear to the business man, and to the newly rich, have gotten the better of the canons of economy and function; and that somebody is picking your pocket of money you might use for better purposes, under the pretext that he is furnishing you with art. The current name for that particular perversion is industrial design".

That was worth saying, for waste of that order goes far beyond the production of styles in motor-cars. It might also be remarked that those in industry who have inclined to take a more conservative attitude, in agreement with the principle of stability which Mr. Mumford invokes, have sometimes been attacked for being unprogressive and withholding the advantages of technical and scientific advance. The position is, in fact, more complex than Mr. Mumford here indicates, and, while there is clearly room for the elimination of technological waste, the great merit of his criticism is the emphasis it places on the need for greater attention to the human factor in technological change. Apart altogether from the economic waste at present often incurred, the impact of technology on society requires fuller consideration from the point of view of the rate of innovation which mankind can endure, without detriment to human personality or the service of human needs as a whole.

---

* Art and Technics. By Lewis Mumford. Pp. v+102. (London: Oxford University Press 1952.) 15s. net.

In Mr. Mumford's own view, the greatest developments to be expected of technics in the future will consist in using machines on a human scale, directly under human control, to fulfil with more exquisite adaptation and with a higher refinement of skill the human needs that are to be served. He does not call for the rejection of the machine, but for its use to better purpose, so that it extends the rational and operative parts of the personality and does not wantonly trespass on areas that do not belong to it. "If you fall in love with a machine," he remarks, "there is something wrong with your love-life. If you worship a machine there is something wrong with your religion." A fuller degree of self-understanding and the restriction of the machine to its proper field would restore to life its freedom and creativeness.

This forthright challenge to the doctrine of 'faster, faster' and the assertion that, once the machine has achieved the power and economy of a good type, it should stand still at least until the creator again places himself above the level of his mechanical creature, is derived from Mr. Mumford's belief that the great problem of our time is to restore modern man's balance and wholeness. He believes that we must give man the capacity to command the machines he has created, instead of letting him become their helpless accomplice and passive victim; and we must bring back into the very heart of our culture a respect for the essential attributes of personality, its creativity and autonomy which Western man lost when he turned to the improvement of the machine. The great triumphs in music and painting of the nineteenth century, for example, depended not merely on the linking of art and technics but above all on the dominance of a belief in the creative human person. The new mechanical order of life made possible by the advance of technics should have released mind and energy for creative processes; but, in fact, it has impoverished our inner life because the machine so largely tends to replace the person and to subordinate his decisions to its mechanical needs.

Nor is this true simply of working hours. The impact on leisure hours has been no less stultifying, as a recent inquiry into the effect of television on social life and habits in Great Britain has indicated. Mr. Mumford's whole purpose in these lectures is to combat this mechanical environment and to restore order, value and purpose on the widest scale to human life. This means finding out how to make our subjective life more disciplined and resolute, endowed with more of the qualities that we have poured into the machine; and it means, also, as already indicated, instead of the pragmatic adaptation of human personality to the machine, a re-adaptation of the machine to the human personality. A human pattern, a human personality, a human tempo and a human goal must transform the activities and processes of technics, curbing them when they become dangerous to man's development and even suspending them until the appropriate political instruments and social institutions have been created.

In his attempt to formulate a working relationship between art and technics, as two essential sides of life, Mr. Mumford next challenges the belief that for the greater part of his existence man is concerned with improving the physical condition of his life, in particular his needs for food, clothing, shelter, security and physical care. The original great contribution of technics, he points out, was not merely to man's physical life, but also to his sanity and general balance. It also gave him a certain respect for the nature of the materials and processes with which he worked. Such respect did not come easily; but, from the beginning, a willingness to accept the hard facts and an understanding of the impersonal nature of things have been a condition of man's success both in dominating Nature and in coming to terms with himself.

Besides this, however, man's success in technics has been associated with a mechanical uniformity and repetitive order. This in itself tends to give man a sense of security, thus turning him towards technics and the object, just as his need for creative expression inclines him to art and the symbol. The problem of our time is that of restoring the appropriate balance between the two needs and tendencies—of establishing the dynamic equilibrium between art and technics, and between spontaneity and necessity, which has always marked the peaks in the development of any civilization. This problem, which is the very opposite of that which faced mankind at the end of the Middle Ages, demands for its solution the restoration of primacy to the human person, and the nurture of those aspects of human nature which have been repressed or displaced by mechanical developments.

Mr. Mumford does not make the mistake of prescribing a simple return to the handicraft processes of earlier centuries, though he considers that in the more advanced Western countries, even until the middle of the nineteenth century, handicraft itself was the mediating factor between pure art and pure technics. Leaving on one side the economic and social consequences of any such large-scale retreat from power production, even if it were practicable, the damage already done to the nature of man by mechanization is too widespread and deep-seated for handicraft alone to offer more than a very limited contribution. Any recent study of the use of leisure testifies to the loss of selectivity and of our powers of assimilation, as is noted by Mr. Mumford. To foster the personal discipline which he considers necessary for the restoration of effective control over the machine is no easy task and may well be a prolonged one.

Despite his skilful diagnosis, Mr. Mumford, like so many before him, is less satisfactory when it comes to prescribing the remedy. He adds little, if anything, to what he suggested in "The Conduct of Life". He sees clearly enough what is to be done; but there is little here to tell us how to do it. He recognizes the value of much that is already being done in industry to give new scope and importance to the workers as human beings. The studies being carried out by the British Institute of Management, the Acton Society Trust and the National Institute of Industrial Psychology are as much in line with the trend of his thought here, as are the earlier investigations of Elton Mayo, to which he refers specifically.

It would appear, however, that Mr. Mumford does not believe that the situation is hopeless, even if he presupposes the rejection of our gratuitous assumption that the existence of a mechanism for manifolding or mass production carries with it an obligation to use it to the fullest capacity. Mankind's mistake has been the reckless multiplication of such mechanisms without forethought as to the ultimate purpose to be served or the effects on man himself. Once this is recognized, claims Mr. Mumford, we achieve freedom.

To recognize and act on this view, however, demands a discipline that cannot itself be based on a new philosophy of freedom. To achieve the integration without which neither art nor technics can prosper is ultimately a matter of will. The recovery of wholeness and balance, and the regaining by man of his creativity and freedom, are essential if mankind is to contain the destructive forces that are now conspiring, almost automatically, to destroy.

Civilization in its present state, Mr. Mumford concludes, is not self-perpetuating. Nevertheless, though he gives no clear lead as to the way back to sanity and control, he is not without hope. Trends towards the renewal of life are indicated, and the ultimate objectives are defined. Nor are these essays on the theme of the impact of technology on society very different in spirit or approach from that of Lord Stamp—they insist that something more than a mere science of social adjustment is required. Like Lord Stamp, Mr. Mumford maintains unhesitatingly that behind all attempts to attune the pace of technological advance to the capacity of human beings for adjustment lies the belief in the value of human persons, and the conviction that failure to respect the human person, and the continued subordination of the individual to organization and to the machine, involves inevitably the downfall and destruction of civilization itself. While Mr. Mumford does not formulate the issue as a conflict of loyalties, like Herbert Read in his address on "Sign and Symbol" at the Present Question Conference last August, he insists quite as strongly that all turns on whether we continue to acquiesce in a civilization that proliferates anxiety in the mind and ugliness in street and factory, or whether we are willing to make the material sacrifice required for man to give expression to his creative nature and restore balance and harmony to life.

# A CLASSIC OF PALÆO-ANTHROPOLOGY

## Les hommes fossiles

Éléments de paléontologie humaine. Par Prof. Marcellin Boule et Prof. Henri V. Vallois. Quatrième édition. Pp. x+584. (Paris: Masson et Cie., 1952.) 4400 francs.

THE second and third editions of this now classic work on fossil man were separated by an interval of twenty-three years. The fact that a fourth edition has now appeared after a further interval of only six years is an indication of the important accessions to the subject which have been made in that short time—accessions which have in some instances strengthened, and in others modified, views previously widely held on human evolution. For example, the remarkably rich finds of the British–Kenya Miocene Expedition in East Africa include remains demonstrating that the Early Miocene anthropoid apes had not yet acquired some of the aberrant specializations of the modern apes, and they have thus now removed one of the main theoretical difficulties which have been raised against the conception of man's derivation from an anthropoid ape ancestry. The discoveries in South Africa by the late Dr. Robert Broom and his colleagues have brought to light a group of extinct hominoids approximating to the apes in the size of the brain but resembling *Homo* in numerous morphological and metrical details of the dentition, in many items of skull structure, and in characters of the pelvis associated with the erect posture. In this new edition these points are now emphasized, and the opinion is expressed that the South African fossils have narrowed to a very considerable extent the morphological hiatus between man and ape which appeared to exist before their discovery, and they also demonstrate that in the course of hominid evolution the expansion of the brain followed (rather than preceded) the adoption of an upright posture and gait. The discovery of further remains of pre-Mousterian man (for example, the Fontéchevade calvaria and the Quinzano occipital bone) confirms the implications of the Swanscombe cranial fragments and the Steinheim skull that the extreme varieties of Neanderthal man were actually preceded by a type of man more closely akin to *Homo sapiens*. On the other hand, the development by Dr. K. Oakley of the technique for estimating the fluorine content of fossil bones has led to the final rejection of great antiquity for the famous Galley Hill skull—a specimen which, because of its 'modern' character and supposed geological age, has led in the past to many speculations regarding the antiquity of *Homo sapiens*.

Marcellin Boule died ten years ago, and the new edition of "Les Hommes Fossiles" would perhaps be more accurately represented as his original book 'edited and revised' by Prof. H. V. Vallois. Prof. Vallois is an eminent authority on palæo-anthropology, and he has accomplished his task well, for he has preserved the individual character of Boule's masterly presentation of the subject of human evolution while at the same time giving adequate representation to those changing points of view which necessarily call for modification from time to time in any rapidly developing subject. There are, however, certain statements and conclusions which still find their place in this edition although it is doubtful if they could to-day withstand a critical analysis. For example, probably little reliance can be placed on the inference as to intellectual functions drawn from the endocranial cast of the fossil skull found at La Chapelle-aux-Saints. The conclusions regarding the alleged simian characters of the foot in the Chancelade skeleton are difficult to accept in the absence of more detailed comparative studies (particularly if the evidence of a footprint of palæolithic man described by Dr. Casteret from a grotto in the Department of Herault is accepted as valid). The facet on the upper canine of the Talgai skull, which was at first taken to indicate an interlocking tooth of simian type, has been demonstrated by Prof. A. N. Burkitt to be nothing more than a facet of contact with the adjacent premolar tooth. The statement that the dingo in Australia was contemporaneous with *Nototherium* and *Diprotodon* is not based on really secure stratigraphical evidence. Finally, it may be suggested that the invention and use of group terms such as "les Préhominiens" and "les Préssapiens" are bound to lead to confusion of thought, since they involve a certain misuse of taxonomic terminology. It has become abundantly clear during recent years that, in discussions on the evolutionary sequence of the Hominidæ, colloquial terms are to be avoided wherever possible, and only the scientific terms proper to taxonomy employed. The terms 'man' and 'human', for example, have come to assume, in popular usage, a very special connotation, and their rigid exclusion in discussions of the evolutionary origin of *Homo sapiens* would no doubt permit a much more objective approach to this problem and also avoid unfortunate misunderstandings.

I have referred above to "Les Hommes Fossiles" as a classic. Under Vallois's editorship it remains a classic—compendious in substance, clear in style, and judicious in its main conclusions. It is also beautifully illustrated. W. E. LE GROS CLARK

# STRUCTURE OF POLLEN

## Plant Morphology and Plant Taxonomy

Angiosperms (an Introduction to Palynology, 1). By G. Erdtman. Pp. xii+539. (Stockholm: Almquist and Wiksell; Waltham, Mass.: Chronica Botanica Co., 1952.) n.p.

THE term 'palynology' was coined in 1944 for the science of pollen grains and other spores, and this recent invention of a name indicates the increasing importance of the subject. Work in this field is proceeding in at least two directions. Pollen grains (and some other kinds of spores) are almost indestructible, so far as their external morphology is concerned, by the ordinary processes of decay as met with under natural conditions. Consequently, they are easily preserved as fossils in peat and other kinds of deposits. During the past two or three decades, the pollen content of peat has been intensively studied in Europe, North America and, to a less extent, in other continents. Spore content of older rocks is also receiving some attention. As a result, the structure of pollen and other spores of existing plants has had to be studied to provide standards for the nomenclature of fossil pollen. Angiosperm taxonomists have long recognized the value of pollen grain characters for classifying genera within certain families such as the Acanthaceæ. Recent researches prove that such characters can be used with advantage much more widely. The careful investigation by improved methods, combined with the examination of the pollen grains of many more species, genera and families, is providing new and extensive data for consideration by taxonomists.

Dr. G. Erdtman has rendered angiosperm taxonomists a great service in providing them with an up-to-date reference text-book to pollen structure. In this work the families of angiosperms are in alphabetical sequence—an arrangement that makes for easy reference and, for the time being probably wisely, avoids any commitments to a phylogenetic or other scheme of classification. There are excellent and numerous illustrations to illuminate the condensed descriptive text. The diversity of size, form, 'markings' and detailed structure of angiosperm pollen grains is extremely striking as one glances through these illustrations. It may be that a new descriptive terminology is unavoidable when a subject is studied extensively and intensively for the first time. One does, however, wonder if the invention of terms has not been carried to unnecessary extremes by some palynologists. In the glossary of this book more than two hundred terms are defined. The great majority of these have been proposed quite recently with direct reference to pollen morphology and are probably of only very specialized use.

The possibilities of pollen morphology throwing light on 'affinities' are evident in Dr. Erdtman's text. After the description of family pollen-grain characters, and diagnoses of special specific examples, valuable comparisons are made with the pollen grains of other families supposed by a previous author or authors to show relationships with the family under consideration. These comparative statements are matters of fact, not matters of speculation. They must in the future receive due attention in any attempt at a general classification of angiosperm families. In addition, there are significant suggestions that some widely accepted taxa are not homogeneous. It would be very valuable to have a classification of angiosperm families, sub-divided or amalgamated as considered necessary, based solely on pollen grain characters. Such a classification would, of course, be a special one serving limited, though important, purposes. With such a classification one could readily utilize pollen characters for improving a general classification and clearly see the taxonomic limits of palynology.

Taxonomists will look forward to further publications by Dr. Erdtman and to a general summary of the theoretical results of his painstaking researches.

W. B. TURRILL

# THE CIVIL SERVICE IN GREAT BRITAIN

## The Fountains in Trafalgar Square

Some Reflections on the Civil Service. By C. K. Munro. Pp. x+202. (London: William Heinemann, Ltd., 1952.) 12*s*. 6*d*. net.

MR. C. K. MUNRO'S reflexions constitute a sensible, and possibly the most successful, exposition of the nature and mind of the Civil Service that we have yet been given. In a very readable book, which should appeal to the man of science though not especially addressed to him, writing under the name he used as a dramatist, Mr. Munro explains lucidly and easily, not simply the work and responsibilities of the Civil Service, and more especially of the administrative class of the Service, but even more of the outlook and mind of the Civil servant and the circumstances which determine his attitude to and his habits of work. Even this can scarcely be called a popular book in the sense of one intended to reach that wider section of the public which most requires to have its misconceptions removed, and to be enlightened as to the close connexion between the activities the Civil Service is required to pursue and the services which that public demands of the State.

A recent B.B.C. inquiry into television has made it only too clear that the chances of reaching that section of the public by means of the printed word is slender. For those who do read his book, Mr. Munro should dispel a good many popular misunderstandings and remove the basis of some ill-informed and unfair jibes. Even more important, by his interpretation of the attitude of the Civil Service and explanation of the reasons behind its practice and procedure in handling such matters as complaints, planning, and the operation of controls, he goes far to promote the understanding and goodwill that are essential for the smooth functioning of government organization and the efficient service of the purposes of the State.

The success of this book is mainly due to the fact that, unlike so many other writers on the Civil Service, Mr. Munro confines himself to the one aim and does not allow himself to be beguiled into examining the problems which are being created for the Civil Service by the demands of a Welfare State. Nevertheless, he shows himself well aware of those problems, and he discusses with humanity as well as imagination such questions as those of controls and planning, the organization of government departments and their relations with Ministers.

Mr. Munro's very success induces the hope that, having explained so clearly the Civil Service as it is, he will now, in another book, discuss the ways in which the Civil Service could find answers to the new problems which are facing us all in the Welfare State and give us his view of the new public service which this new conception of the State requires. That hope is the more warranted because Mr. Munro displays to the full in this book the very qualities that can contribute most to bridging the gap between Civil servants and the community they serve, and to stimulating the circulation between the Civil Service and other professions which is now so desirable.

R. Brightman

# COMPARATIVE ANIMAL PHYSIOLOGY

## Comparative Animal Physiology

By Prof. David W. Bishop, Prof. Frank A. Brown, Jr., Prof. Theodore L. Jahn, Prof. C. Ladd Prosser and Prof. Verner J. Wulff. Prof. C. Ladd Prosser, Editor. Pp. ix+888. (Philadelphia and London: W. B. Saunders Co., 1950.) 63s.

In physiological research, difficulties of technique or of interpretation may sometimes be overcome by extending the investigation to include other methods or different species. It is natural that mammalian physiology should be studied intensively, but in fact the investigation of other forms has contributed greatly to the solution of many fundamental problems, and continues to do so. The advances recently made in the knowledge of nerve impulse transmission show how various methods can profitably be brought to bear on a problem.

In view of the outstanding intrinsic interest and possible wider complications of many aspects of non-mammalian physiology, it is surprising how few are the texts devoted to comparative animal physiology. This book provides a notable contribution in this field, and it should be of value to many classes of readers.

Prof. C. L. Prosser appropriately begins by stating his concept of the functions and aims of comparative physiology: "Comparative physiology treats of organ function in a wide range of groups of organisms. Comparative animal physiology integrates and co-ordinates functional relationships which transcend special groups of animals. It is concerned with the ways in which diverse organisms perform similar functions. Genetically dissimilar organisms may show striking similarities in characteristics and response to the same environmental stimulus. By the same token closely related animals frequently react very differently to their surroundings. While other branches of physiology use such variables as light, temperature, oxygen tension, and hormone balance, comparative physiology uses, in addition, species or animal type as a variable for each function. The generalisations which emerge from this experimental approach are important as biological principles which often aid in solving problems of cellular or special group physiology".

In presenting animal physiology from this point of view, the authors do not deal exhaustively with mammalian or cellular physiology, but these are included in enough detail to present an adequately balanced picture. The book is intended for advanced undergraduate or graduate needs, and to "introduce investigations to particular branches of the subject". In view of this, descriptive physiology of the various species is, of course, a prominent feature of the book, while ecological and evolutionary implications and biological generalizations are introduced at appropriate places, and emphasized at the end of chapters.

The whole book bears evidence of much thought and care, and the declared objectives are kept well in evidence throughout. The scope of this extensive text is very wide, so wide, in fact, as almost to defy a truly critical detailed appraisal by one person. The inclusion of so much material demands a concentrated type of exposition, which in this book is shown to be compatible with admirable clarity and precision. There are many excellent tables of quantitative data on various physiological and biological aspects of many kinds of animals; the variety and scope of these add appreciably to the value of the book. Throughout the text, attention is directed to numerous important questions in need of solution.

The bibliography is stated to be selective rather than comprehensive, and if occasionally an apparently important paper is not included, this fact must be remembered. Also, the student of mammalian physiology must be reminded that this branch is not intended to be stressed, although in fact most of mammalian physiology is very satisfactorily covered. The bibliography contains more than three thousand references.

The text is almost free from typographical error; on p. 121 of my review copy, however, part of the text seems to have been omitted.

The authors are to be congratulated on the ambitious conception of this book, its originality, wide scope and excellent balance. Their work has made easily accessible a mass of information useful to student and specialist alike, and the book should provide an added stimulus to the study of animal physiology on a comparative basis.

W. Burns

## Mind and Life

An Essay in Simplification. By A. G. Tansley. Pp. xi+172. (London: George Allen and Unwin, Ltd., 1952.) 15*s*. net.

THE author of this book is an ecologist who has previously written an exposition of psychology. He now presents this further volume, which he describes in a sub-title as "an essay in simplification". This is a discussion of various aspects of psychology, and its scope is shown by the chapter headings, some of which are: the structure of the mind; the energy of the mind; the functions and limitations of psychological concepts; instinct, heredity and environment; causation, determinism and free will; love and sex; the strength and weakness of psycho-analysis; the family and the community; the individual and the community; psychological reality and spiritual values; etc.

There is nothing new in this book—it is mainly a re-statement of the views of Freud, McDougall, Trotter and others. Its value, therefore, must lie in the clarity of exposition. This is very good, and the author does state clearly and intelligibly the theories which he describes. Mainly he accepts the Freudian point of view, and his descriptions of mental structure, and so on, are excellent. Not everyone would accept his views on free will, which he regards as possible within a limited sphere, since many would insist that every action is determined. He suspects the idea that the mother–child relationship is a sexual one, but admits (p. 103) that "it may, as in the Oedipus situation, run into the specifically sexual channel". This timidity is shown especially in his discussion on religion. Here he takes a leap into the dark and, abandoning any psychological basis, states (p. 106) that "The best evidence for the belief in spirit as the ultimate reality is derived from the phenomena of religious mysticism".

Those unacquainted with modern psychological theories will find the book of interest. It is well printed on non-shiny paper and is attractively bound in apple-green cloth. There is no index.

CLIFFORD ALLEN

## Hydroponics

The Bengal System. By J. Sholto Douglas. Pp. xii+147+17 plates. (Bombay and London: Oxford University Press, 1951.) 10*s*. 6*d*. net.

THE growing of plants in sand, gravel or other inert medium with the aid of nutrient solutions has now become firmly established as a commercial method in many countries. In Great Britain its use has been confined, for obvious reasons, to the cultivation of glasshouse crops; but in other parts of the world, where shortage of water or unsuitable soil makes normal outdoor growing impossible or uneconomic, soilless cultivation holds out promise as a means of production, especially of food crops.

Mr. J. Sholto Douglas, an immensely enthusiastic amateur, became fired with the idea of using simplified techniques for food production in North India and, during some years of work in Bengal, produced results which, if not quite so startling as his enthusiasm might lead one to believe, were at least of great interest. He has embodied in this small book an account of the practical systems he developed, which are workable, so he claims, by Indian labour.

While he confines himself to this practical description of his own experiences, the book is interesting and useful. Unfortunately, he runs outside his brief and attempts in a short space to give an account of the underlying principles of plant nutrition in general and of soilless cultivation methods in particular. Here he is on unsafe ground and perpetrates some major errors of principle and fact. His lists of "suitable" solutions, for example, are entirely uncritical and in some cases absurd, while when he attempts to deal with certain unrelated scientific findings, such as colchicine treatment and the use of plant hormones, he goes entirely off the rails. If the book should see a second edition, it is to be hoped that the author will delete these irrelevant and unnecessary parts.

R. H. STOUGHTON

## Exercises in Experimental Physics

Edited by N. C. B. Allen and Dr. L. H. Martin. Pp. xiii+237. (Melbourne: Melbourne University Press; London: Cambridge University Press, 1951.) 30*s*. net.

THIS book is specifically written to supplement the lecture courses in the second year of the B.Sc. in the University of Melbourne; but, of course, it could be used equally well by students of any university pursuing a similar course.

It is gratifying to know that the students at Melbourne are encouraged to read about the experiments before carrying them out, and to this end sufficient theory is given in the book to enable the experimenter to have an intelligent understanding of what he is about to do; in addition, references are made to suitable texts for further reading—a good feature.

The course is a very comprehensive one, if, as it seems, it is to cover one year of work only, and this latter fact probably explains the apparent lack of balance between subjects. For example, only four pages are devoted to the heat section, and a similar number to sound; presumably, courses for other years restore the correct balance. The work is thoroughly up to date in its approach and execution, and includes a section on the Geiger counter as well as work on radioactivity. The first chapter is devoted to an account of observations and statistical theory, which, it is hoped, students will thoroughly digest, and there is a useful appendix dealing with units.

## Annual Review of Physical Chemistry

G. K. Rollefson (editor), R. E. Powell (associate editor). Vol. 3. Pp. x+416. (Stanford, Calif.: Annual Reviews, Inc., 1952.) 6 dollars.

WITH the publication of this, the third volume of the "Annual Review of Physical Chemistry", the venture begun under the capable editing of G. K. Rollefson and R. E. Powell in 1950 may be said safely to have passed the experimental stage. The general pattern is now clear: the articles can be divided broadly into two classes—the perennials, or annual reports proper, in which each year the progress over the year is given; and the special topics, varying from year to year, in which the reviewer is allowed to develop his subject more fully to cover a longer time period. The perennial review is perhaps the more difficult to do well, but some safeguard is provided by the policy which brings a new author to each subject annually.

Vol. 3 contains an essay on the quantum theory of valence (C. A. Coulson), topical reviews on polymeric electrolytes (P. Doty, G. Ehrlich) and on bond energies and distances (G. Glockler), a masterly summary of the theory of liquid solutions (G. Scatchard), a discussion on some aspects of photosynthesis (M. Calvin *et al.*), and fourteen other articles, in which virtually the whole field of physical chemistry is covered.

H. A. SKINNER

# ROBERT HOOKE, 1635–1703

By Prof. E. N. da C. ANDRADE, F.R.S.

ROBERT HOOKE, one of the most inventive and far-seeing minds in the history of physical science, was born at Freshwater, in the Isle of Wight, on July 18, 1635, and so was some six years senior to Newton. He was a weakly child and, throughout his life, was afflicted by poor health. His diary for the years 1672–80, edited by H. W. Robinson and W. Adams (see *Nature*, 136, 358; 1935), is full of records of suffering and of the divers medicines which he took in the hopes of alleviating his distresses—catarrh, terrible headaches, vomiting, sleeplessness and fearful dreams. Chronic inflammation of the frontal sinuses was probably one of his troubles. If it is abundantly clear that he was often sharp-tempered and irritable, generally under provocation, it must be remembered that a night when he slept well was for him a matter worthy of special record.

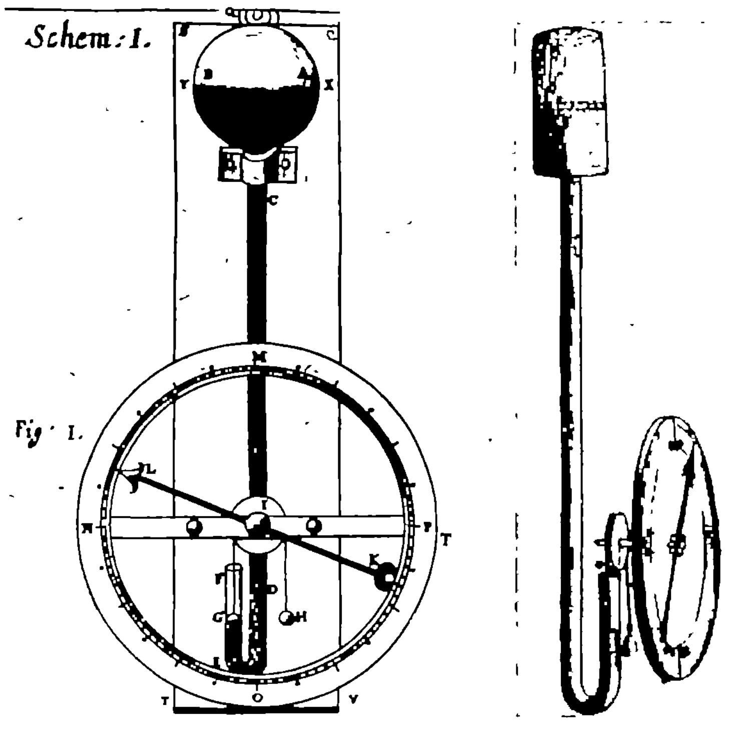

Fig. 1. Hooke's wheel barometer; on the left is the diagram as given in the "Micrographia"; on the right Hooke's original sketch, in the possession of the Royal Society[*]

He went to school at Westminster, one of the best schools in the country, at the time under the famous Dr. Busby, with whom he was in later life on very friendly terms. For example, he designed for his former headmaster the church at Willen in Buckinghamshire, which reminds us that Hooke was a rather more than competent architect, an example of his astonishing versatility. From Westminster he went to Oxford, where he had a chorister's place at Christ Church, which presumably implies that he had a good singing voice[*]. Oxford at that time, with such men as John Wallis, Seth Ward and John Wilkins, was a great centre of the new "Experimental Philosophy", the revolt against the authority of the ancients in matters of science which was soon to find its expression in the formal foundation of the Royal Society. Here Hooke became assistant to Robert Boyle, probably recommended in the first place to that wealthy and gentle young genius by his extraordinary manual skill. He made, for example, for Boyle the pump figured in "New Experiments Physico-Mechanical", 1660, which was the first air pump constructed in England and a great improvement on the earlier Guericke pump. In 1661, while still with Boyle, he published a little book dealing with capillary phenomena, which contains no capital discovery, but many acute observations and suggestions. In the following year he was appointed 'curator' by the newly-founded Royal Society, a poorly paid post with heavy duties. From then until 1682 his name and work were closely connected with the Society: he furnished it with abundant experimental demonstrations, with a variety of papers, some of them embodying original work of first importance, and, in general, did much to invigorate the Society and hold it together. His financial circumstances were much improved after the Great Fire of 1666 by the lucrative work which he carried out as City Surveyor, in which capacity he was chief assistant to Christopher Wren in the matter of rebuilding the City of London. Incidentally, Wren was one of the great men who were on very good terms with Hooke: Evelyn and Sydenham were others.

Hooke acted as secretary to the Royal Society from 1677 until 1682, and in the period 1679–82, when the *Transactions* were in abeyance, produced the *Philosophical Collections*, a record of scientific work at home and abroad. After giving up the secretaryship he still made frequent communications to the Society, until about 1696, when his health broke down completely. He died, after some wretched years, on March 3, 1703.

Hooke's scientific work covers an astonishingly wide range and most of it bears the stamp of a powerful genius. If any single man deserves to be called the originator of the modern scientific instrument, it is Hooke. He invented all the meteorological instruments. His wheel barometer was long the standard instrument and can still be seen in use. He made a properly calibrated thermometer, with the freezing point of water as zero and a standard volume expansion. He invented the first hygrometer with an index, based upon the properties of the beard of the wild oat, and the first good wind gauge, as well as a self-measuring rain gauge. He also devised recording instruments, which worked, if but inter-

---

[*] It had occurred to me that possibly "a chorister's place" could be a surviving name for some kind of a sizarship, but Canon Jenkins, who is a great authority on the subject, assures me that the place does imply that Hooke had a good singing voice.

[*] Figs. 1, 2 and 3 are reproduced by courtesy of the Royal Society from the Wilkins Lecture delivered by Prof. E. N. da C. Andrade on December 15, 1949 (*Proc. Roy. Soc.*, A, 201, 439; 1950).

Fig. 2. From Hooke's paper on "A Method of Making a History of the Weather"

mittently, and planned an excellent scheme for proper meteorological records. In particular, he viewed the study of the weather quite in the modern spirit, as a matter of physical law applied to solar radiation, the rotation of the earth and other factors, and was quite clear that the behaviour of the barometer was an important factor in foretelling storms.

In astronomy he invented telescopic sights and clearly pointed out their advantages, treating the question of resolving-power with great understanding. His instruments were furnished with screw controls and were of excellent design, embodying many pioneering features. He proposed, and published a figure of, the first clock-driven telescope. In connexion with his astronomical instruments he invented the universal, or Hooke's, joint.

In horology there seems to me little doubt that he invented the modern spring-controlled balance wheel, although there is a long history of dispute in this connexion. On the other hand, there seems to me insufficient evidence for ascribing to him the anchor escapement, with which he is usually credited.

He invented the efficient compound microscope and devoted particular attention to methods of illumination for microscopy, which enabled him to obtain the striking results illustrated in the plates to his renowned "Micrographia". With this microscope he made a number of fundamental discoveries in the biological field, such as the structure of a feather and the cellular structure of plants: he introduced the word 'cell' into biology. The impressive figures of the gnat, the flea and the louse show great observation and great precision and he carried out fundamental work on the life-cycle of the gnat. He was the first to propose immersion lenses, pointing out clearly their advantages. The 'Micrographia' contains a great body of work in fields quite outside the microscopic world, to some of which reference is made elsewhere in this account.

Hooke has to his credit a large number of other instruments—the iris diaphragm, the refractometer for liquids, helioscopes, sounding machines and a device for bringing up samples of sea water from depths. It seems that he invented a multiplying and dividing machine. The spirit level which he made was not the first, but quite likely he had not heard of that of Thevenot, which anticipated his. His mind was so fertile, however, that it is not easy even to list the devices which he poured out, usually with only brief notes.

His contributions to scientific observation and thought form an equally impressive collection. In fundamental astronomy his services were completely overshadowed by Newton, but in 1674, before Newton had published anything on the subject, Hooke, with his extraordinary acuteness, had stated clearly that the problem of the planetary motions was one of simple dynamics, and that the closed orbits were due to gravitational forces deflecting the planets from the straight-line courses that they would otherwise pursue. A little later he put forward the inverse square law. He was, however, not sufficient of a mathematician to prove that this would lead to elliptic orbits, as Newton did; nor, of course, if he had been able to do this, had he the preternatural genius and application of Newton to develop the theme as Newton did. His speculations on the structure of the universe show his accustomed perception—"To me indeed the Universe seems to be vastly bigger than 'tis hitherto asserted by any writer". He was a brilliant observer: his astronomical observations alone would have secured his name a place in the history of science.

As a geologist he was a noteworthy pioneer, who clearly realized that fossils were a record of times past, and he treated the evolution of the globe in a modern spirit, in strong contrast to the fantasies prevailing in his time. It will perhaps suffice here to cite Sir Archibald Geikie, who speaks of his work in geology in the highest terms, referring in particular to "his remarkable powers of acute observation and sagacious reflection", terms which can be applied to all his work.

Hooke's work on combustion and respiration, if small in volume, was fundamental: with his usual perspicuity he realized the connexion between them and also the function of oxygen, although he did not further identify the gas than to say that it was copiously contained in saltpetre. He actually tried experiments with his own person on breathing at reduced pressure, enclosing himself in a tun surrounded by water.

Turning to physics, we have the familiar Hooke's law, demonstrated experimentally in a variety of ways; but that he also pointed out that, if the restoring force is proportional to the displacement, the vibrations must be isochronous, is less familiar. He treated crystal structure in a modern manner, building up crystal forms out of spheres. He was clear as to the nature of heat: it was "nothing else but a very *brisk* and *vehement agitation* of the parts of the body", a conception which he amplified. In light he made striking observations on the colours of thin plates. His theory of light contains much that is strikingly novel for the time, but when he treats of colour he does not show his usual clarity. It is not usually known that he carried out fundamental experiments in sound, but he did so, inventing, for example, Savart's wheel some hundred and forty years before Savart.

Any short account of this kind dealing with Hooke's achievements tends to become a list, but this is almost inevitable. He did so much, and all of it was interesting, most of it astonishing for the date. He would take up a subject, work intensely at it for a short time—on occasion for a very short time—make an essential advance and then find his attention absorbed by some other subject. In character he was a complete contrast to Newton: whereas Newton would, as he said, keep the subject (usually one of fundamental significance) constantly before him until the first dawnings opened little by little into the full light, Hooke never concentrated on any one subject for long and the subject might be anything to which his attention had been drawn. Newton felt no need to communicate his discoveries and abhorred controversy of any kind: Hooke seems to have taken a lively pleasure in describing his latest advance and certainly did not shun the arena. Newton's was, of course, the greater mind, but Hooke was a very great man, of immense inventiveness and industry, the greatest experimental skill and rare intuition, who covered a prodigious range. As Lalande, considering his books, says: "Dans ces ouvrages on trouve les idées de la plupart de nos instruments modernes: c'était le Newton de la mécanique".

# HABITAT, VEGETATION AND MAN*

By Prof. W. H. PEARSALL, F.R.S.

University College, London

THOSE of us who have to deal with the out-of-the-way parts of Britain are aware that there are two problems which merit more consideration than they normally receive. These problems are those associated with production and with preservation.

It is still not generally appreciated that a large part of Great Britain, almost a third, is still biologically unproductive, supporting little but a deer or a sheep on thirty or forty acres of surface. One problem arises as to whether it is possible to raise the production of these areas to one more in keeping with our present economic position, for the day is past when we can afford to keep so large a part of our island in what is practically a sterile condition. Along with this problem there is a related one, of preserving for scientific study some of the remnants of the original native flora and fauna. This is one of the roles of the newly created Nature Conservancy—a function which could, no doubt, most easily be fulfilled by re-creating vanished units of vegetation and animal life on the less-valuable areas.

Both of these problems, however, involve a detailed knowledge of the natural trends of soil and vegetation in these islands and particularly in the unproductive areas. It is noteworthy that many of these wastelands, for example, the heaths of south-east England from Yorkshire south, are associated with the signs of occupation by early man, and it becomes pertinent then to ask whether they were always as inhospitable and unproductive as they may be to-day or whether they have changed since they were first occupied by man. Different sorts of evidence suggest that most of these areas were once forest-covered and that since man first occupied them their soils and general productivity must have greatly diminished. An area of particular interest is the Breckland in East Anglia. The pollen-analytical studies of Drs. Godwin and Tallantyre on mud-cores from Hockham Mere show clearly that this area was forest-covered for much of the post-glacial period. However, after the date of human occupation the area became deforested so that grass and herb pollen replaced that of trees. In addition, the appearance at this time of the pollen of plants such as *Plantago* and *Artemisia*, weeds of cultivation, suggests here, as elsewhere in Europe, that forest clearance was associated with human occupation. Similar evidence is available for Danish heaths, while deforestation of the heather moors in Yorkshire appears also to have taken place since the Bronze Age.

---

* Substance of a Friday Evening Discourse delivered at the Royal Institution on December 12.

Apart from the debased condition of existing Breckland soils (which were described by Dr. A. S. Watt) there is, at present, no direct evidence of changes in soil conditions in this case; but results in the similar climate of eastern North America have given abundant evidence of the soil degeneration following deforestation, shown both by the lower nitrogen content which results and also in the greater soil erosion which has left its mark in the more inorganic character of recent lake sediments.

The study of lake sediments promises, indeed, to throw valuable light on post-glacial trends in soil conditions, for in many cases sediments of this type must be samples of the actual soil materials. The difficulty will be to allow for changes which take place in transit, or during and after deposition. Some evidence is already available from the English Lake District which poses the problems and suggests intriguing solutions.

In general, the post-glacial sediments in lakes like Windermere and Esthwaite Water appear to have been uniform in character during at least the first half of the post-glacial period or rather more. Later, and particularly during the past three thousand years, there are various types of change in the character of the sediments. If each of these changes were considered alone, several possible causes for each might be suggested, but if, as seems probable, all are connected one to the other, then all seem to run parallel to the onset and development of deforestation, and it remains for further inquiry to elucidate the connexions and to analyse the basal controlling influences.

Deforestation in the Lake District appears to have started in the second millennium B.C. Apparently it proceeded rapidly after the Norse occupations (say, from A.D. 1100 onwards) and reached a maximum in the sixteenth century. Following this, the lake muds corresponding in time show a minimum of organic matter which is attributed to soil erosion following deforestation. Parallel changes which apparently became intensified at this time include such features as a diminution in the electrical conductivity of the mud, and an increase in its acidity. The latter is particularly well shown in mud cores from the Esthwaite Fen, where it can be closely correlated with the diminishing base-saturation of the mud colloids.

The three features of the more recent mud-layers, decreased conductivity, decreased base-saturation and increased acidity, suggest that the soils from which the muds were derived may have suffered pronounced leaching in the course of time. The existence of rapid soil leaching under present-day climatic conditions was, of course, first demonstrated by Salisbury on various British dune systems and has since been shown elsewhere, especially by Hissink for Dutch 'polders'. The evidence from lake-muds apparently confirms the existence of this tendency in the past; it may also show that leaching proceeded at widely different rates at different times. If the present indications on this point are confirmed, leaching appears to have been extremely slow under the continuous forest-cover of the earlier half of the post-glacial period and to have been greatly accelerated as deforestation became more and more pronounced. There is, however, no evidence which serves to decide whether deforestation and soil deterioration in the Lake District were the results of 'natural' changes or of human action. The climatic deterioration known to have occurred just before the Christian era in north-west Europe may well have been a decisive factor in these changes, and it may be a matter of chance that its action should have coincided somewhat closely with the time of extending human settlements. Certainly one must be reluctant to ascribe the earliest deforestation of so many different parts of Britain to Neolithic man—until more is known of the numbers of individuals in each locality.

Any general conclusion which can be drawn from this type of work seems only to confirm the general impression reached by ecologists, that many types of 'marginal' land can only be really productive under forest. Undoubtedly much of northern Britain at least should never have been deforested, and it seems that the simplest biological method of re-creating lost fertility in such areas may be by afforestation. Further, these areas are now invariably of low nitrogen status and it seems to follow that alternative forms of land-use, if any exist, should properly aim towards products chemically different from the bread and beef of our lowland agriculture. A sound policy should aim first at the redevelopment of a more stable and productive soil status, and only later at high yields.

# THE FIGHT AGAINST FILARIASIS IN THE PACIFIC

By Sir PHILIP MANSON-BAHR, C.M.G.

FILARIASIS remains the dominant scourge of the Pacific, especially in those islands mainly inhabited by Polynesians. These palm-covered coral-reefed atolls constitute what are popularly known as South Sea Islands and are made familiar to many in the film of the "Blue Lagoon" or by the vivid writings of Robert Louis Stevenson. There amidst fantastic and beautiful surroundings the filaria is rampant, finding conditions ideal for its propagation. Malaria, which in other parts of the tropics and indeed throughout Melanesia is the greatest bar to prosperity and progress, is here quite unknown. It is now more than seventy years since the transmission of the filaria (*Wuchereria bancrofti*) through the mosquito was proved by Sir Patrick Manson, and some forty years have elapsed since the Pacific filaria[1] was recognized as possibly a separate entity and its spread by a special distinct species of mosquito peculiar to the Pacific islands proved by me. Nevertheless, comparatively little had been done up to the present to transform these scientific facts into practice.

Filariasis and its maximal expression, elephantiasis, have existed in Polynesia for many centuries, and the disease appears to have been spread from one island to another by migrating Polynesians during the fifteenth century. In the Central Pacific the area dominated by filariasis is enormous: an area delimited by long. 170° E. to 130° W. and lat. 10° N. to 24° S. in a vast oblong some 3,500 miles in length and 2,200 in breadth containing well over a thousand islands and a population of about 370,000 Polynesians.

In 1912 I was able to show that the chief vector of the non-periodic filaria in the Fiji Islands was the prevalent black-and-white striped mosquito which had been described by Theobald as *Stegomyia scutellaris* from specimens sent to him by F. P. Jepson[1]. This species has had a chequered career as regards terminology, being renamed *A. variegatus* and now finally *Aedes scutellaris pseudoscutellaris* by F. W. Edwards. The ecology and bionomics of the species have been thoroughly studied since by O'Connor[3], by Buxton and Hopkins[4], by R. W. Paine[5], and by Byrd, St. Amant and Bromberg[6].

Now the surprising discovery has been made by E. N. Marks[7] that, in what was thought to be a homologous species, two morphologically similar identities exist and that a new species, *Aedes scutellaris polynesiensis*, has to be recognized as valid, distinguished from *Aedes s. pseudoscutellaris* by the shape of the lobe of the coxite of the male. *Polynesiensis* is the most important and widespread species in that area of the Pacific now under consideration. This entomological problem is further complicated by the presence of a third, closely similar and related species of *Aedes* in Fiji, *Aedes scutellaris horrescens*, the female of which is indistinguishable from *pseudoscutellaris*, which was described by F. W. Edwards in 1935[8]. This is a forest-frequenting form and breeds in tree holes of coconut palms, tree ferns and other forest trees. The main distinction lies in the larvæ, which are readily separable as being more hairy.

The recent researches in Fiji by P. Manson-Bahr and W. J. Muggleton carried out in 1950 have now been published[9], supporting the arguments originally proposed in 1912 that the Pacific filaria should be considered as a separate species, for which the name *Wuchereria pacifica* has been proposed. From the work of J. J. C. Buckley[10] on the adult worms collected from Samoa and Fiji, it appears that some morphological differences can be recognized. In *W. pacifica* the head is oval in outline; in *W. bancrofti* it is round. The tail of the female lacks the bulbous swelling seen in *W. bancrofti*, and the length of the adult specimens, both male and female, is considerably smaller. Added to this, the non-periodic habit in the blood of the microfilaria of *W. pacifica* is adapted to the biting habits of its insect intermediaries *A. polynesiensis* and *A. pseudoscutellaris*. The fact that it does not develop normally in *Culex fatigans* or in *Aedes ægypti* reinforces the argument of distinct specificity. In contrast, the nocturnal microfilariæ of *W. bancrofti* are adapted to the night biting habits of *C. fatigans* and *Anopheles punctulatus farauti*, mosquitoes which act as the optimum intermediaries in Melanesia.

The geographical distribution of these two forms of filaria appears to be quite distinct, and *W. pacifica* is to be found in those Pacific Islands east of 170° E. It has been further suggested by me[11] that wherever *W. bancrofti* occurs it is the result of a domiciliary infection acquired during the night hours. Therefore, women and children are infected almost as heavily as the males, whereas in *W. pacifica* it is contracted in the daytime in the bush and plantations away from habitations and therefore this form of filariasis should be regarded as a rural infection. Men are consequently more heavily infected than women owing to their occupations in the open air in gardens and plantations. That the site of the infecting bites may also be important is shown by the frequency of elephantiasis of the arms in the Pacific as compared with British Guiana, where *W. bancrofti* is common and elephantiasis of the legs the rule. Repressive measures have to be based on these premises. In the nocturnal form the infecting mosquitoes must be attacked inside dwellings; in the non-periodic form in the immediate surroundings of dwellings and in the bush. The former (the nocturnal form), as has been shown by Giglioli[12] in British Guiana, is comparatively easy to eradicate.

Little repressive work against filariasis had been undertaken prior to 1942 in Fiji. In that year D. W. Amos[13], a retired business man who was an amateur entomologist, undertook an educational survey of the mosquito pest within the town of Suva. In 1943, appointed senior mosquito inspector, he commenced to train Fijian assistants in anti-mosquito measures and this scheme has since developed into the Mosquito Control Service. By these means the Fijians themselves have been made responsible in their villages and townships for the conduct of the anti-filariasis campaign. At the Central Institute in Suva Amos, and since Amos's death in 1949, Isimeli Rakai, his chief assistant, have trained classes of selected Fijian youths in this work, which comprises the structure and identification of the adult and larval stages of Fijian mosquitoes, and many other allied subjects. Up to 1948, more than 45,000 blood examinations had been made and an overall microfilaria rate of 18 per cent established. A training manual on mosquito control[14] by D. W. Amos was published in 1944 and revised in 1947. A shorter edition in the Fijian language and embellished with original cartoons was produced by Isimeli M. Rakai[15] in 1950.

There is no doubt that the Mosquito Service has done, and is doing, great work for Fiji, and the results of this campaign are already apparent. This was evident during my visit to Fiji in 1950. In the field, the Mosquito Service teams have been most active in clearing up the surroundings of villages, in filling in tree holes, burning coconut shells and debris, cutting down jungle, burying refuse heaps and generally making the village Fijians 'mosquito conscious'.

Now the battle has been joined by American workers in Tahiti and the preliminary results of their work have been published.

The anti-filariasis campaign in the Pacific has also received a great stimulus by the creation of the South Pacific Commission in 1949 and of which the first conference assembled in Suva in May 1950; afterwards a select group met in Tahiti during August 21–September 1, 1950, and a summary of the proceedings has been issued[16]. This was composed of delegates from French Oceania, New Zealand, Australia, Fiji, New Caledonia, Cook Islands, Samoa, Hawaii, University of California and other American interests.

Filariasis work in Tahiti is being conducted at the Institut de Récherches Médicales de l'Oceanie Française, Papeete, Tahiti. In July 1951, an annotated bibliography on filariasis, elephantiasis and related aspects in the South Pacific area was issued[17] by E.

Massal, executive officer, and D. J. Kerrest, research officer, Health Department of the South Pacific Commission.

### Mosquito Control

In addition to the work in Fiji, medical officers in Samoa have been investigating methods of mosquito control in suppressing filariasis. In their paper, Jachowski and Otto[18] endeavoured to determine the maximum zone of infectivity in native villages by dissecting specimens of *Aedes pseudoscutellaris* (probably *A. polynesiensis*) at selected collecting stations situated at various measured distances from the living quarters. In doing so, they examined more than 2,300 specimens of *A. polynesiensis*. They were surprised to find that the highest incidence of filarial infection (in the thorax) was not in the immediate vicinity of the huts inhabited by the Samoans, as might well have been expected; but the 'index of transmission' was very high in the bush and garden trails 175–275 yards from the centre of all the villages investigated. The age and sex distribution of microfilaræmia in Samoans, added to the habits of the villagers, and the well-ascertained biting habits of the mosquito vectors, which coincide with the visits of the gardeners to their plots, all support the conception of the non-domestic transmission of this filariasis. In some details their findings differ somewhat from similar researches by Byrd, St. Amant and Bromberg some few years earlier (1945), when they found the highest rate of mosquito infection at a range of 25 yards from the village centre.

The merits of mosquito control and drug suppression combined and contrasted have been employed on the grandest scale so far in Tahiti, where Beye[19] and his colleagues have now issued their preliminary report upon the suppressive measures they have initiated for the control of filariasis, covering the period November 1948–September 1950. Their schemes were carefully planned and the total area was divided into nine divisions, including the adjacent island of Maiao. They, too, employed collecting stations for adult mosquitoes in order to determine their densities. There were no less than three 'resting' and an equal number of 'biting' stations in each selected area, where recordings were made two to three weeks prior to the establishment of control measures.

Next, the microfilariæ-rate per 20 c.mm. of blood had to be determined for each area, both before and after treatment with 'Hetrazan'. In order to obtain reliable data upon which to base their conclusions, measures varied in different areas, keeping as a control one with a microfilaria-rate of 38·6. In other areas different methods of suppression were instituted, some with 'Hetrazan' prophylaxis, others with sanitation and DDT. The effect of the several methods on the percentage of persons with microfilariæ was estimated at six and twelve months after the measures were commenced, and thus it was ascertained that a noticeable drop occurred in each of the four areas where 'Hetrazan' was administered, whereas wherever anti-mosquito measures were instituted there was a drop in the numbers naturally infected to 0·6 per cent.

### 'Hetrazan' Prophylaxis

Clinical work on 'Hetrazan' in human filariasis was initiated by Santiago-Stevenson and others[20] on twenty-six persons harbouring *W. bancrofti* in Puerto Rico. When it was given by the mouth, in doses of 0·5–2·0 mgm. per kgm. body-weight three times daily, the number of microfilariæ was greatly reduced by the second day and in some 34·6 per cent they disappeared entirely. Afterwards, work was continued in British Guiana[21] and on the Island of S. Croix[22], and again substantial reductions of microfilariæ were obtained which persisted for three to twelve months.

The exact dosage of 'Hetrazan' and the length of the course necessary to banish microfilariæ from the blood has not even yet been finally determined. I found[23] in Fiji that, if the deep venous blood is examined, although no microfilariæ may be present in the peripheral circulation, they can usually be demonstrated. This leads to a consideration of the mode of action of 'Hetrazan'. Hawking, Sewell and Thurston[24] have shown that microfilariæ (*W. bancrofti*) in enclosed cavities, such as the pleura, or in a hydrocele sac, are not affected by 'Hetrazan'; but that, after treatment, they congregate in the liver, where they are attacked and devoured by leucocytes. It appears probable that 'Hetrazan' modifies the microfilariæ in some manner so that the leucocytes are attracted to them as if by some opsonizing effect.

It would seem that a very considerable reduction in numbers results from comparatively small doses of 'Hetrazan', but that larger ones are more lasting. Halawani[25] in Egypt treated ambulant cases (*W. bancrofti*) with 'Hetrazan' in doses of 0·9–2 mgm. per kgm. three times daily. In Indian nocturnal filariasis (*W. bancrofti*), Raman and colleagues[26] gave 0·45–2·2 mgm. per kgm. similarly for twenty-one days with a similar result. In East Africa, Laurie and associates[27] have given 'Hetrazan citrate' in doses as high as 12 mgm. per kgm. every twelve hours for three days to banish microfilariæ from the blood. Nine moderately infected patients received a single dose of 20 mgm. per kgm., and it was found that microfilariæ were absent from the blood two years later; but it is laid down that those patients with greater numbers of microfilariæ are definitely more difficult to sterilize than those with smaller numbers.

The most detailed account so far of the control of filariasis with 'Hetrazan' has been published by McGregor, Hawking and Dean Smith[28] at the Medical Research Council's Field Station in the Gambia. The dosage of 'Hetrazan citrate' was 25 mgm. per kgm. daily for five days. Of 154 infected persons who completed the prescribed course, 64 per cent had their blood free from microfilariæ so long as ten months later. In the remainder who did not respond so satisfactorily the parasitæmia was substantially reduced.

It is not surprising to learn that these large doses were not well tolerated and toxic effects appeared in one quarter. This form of medication soon became unpopular and it was only with great difficulty that the trial was completed.

In non-periodic Pacific filariasis, the microfilariæ are possibly more difficult to exterminate. In addition to the work of Beye and colleagues in Tahiti, Gaillard and Mille[29] gave small doses—2 mgm. per kgm. three times daily for seven days—and microfilariæ were banished in 87 per cent for about four months. It is still open to question whether one large loading dose is more effective in reducing microfilaræmia than a more prolonged course of smaller ones.

It would thus seem probable that the disproportion of the severer manifestations in the two forms of filariasis, nocturnal and non-periodic, discussed in this article reinforces the argument that, in the former (*W. bancrofti*) infections and in the latter (*W. pacifica*), we are dealing with separate entities which necessitate different methods of prophylaxis and possibly of treatment as well. (The statement made by McGregor and colleagues that out of 603 Gambians examined there were only six with signs of filarial disease and that the people regard it as altogether of minor importance must also be borne in mind.)

Owing to the uncertainty of the dosage and length of treatment with 'Hetrazan' in order to banish microfilariæ from the peripheral blood for a sufficient time to render mass application a practical proposition, added to the almost insuperable difficulties which arise in carrying through such a programme in Polynesians, there exists at present a prejudice against this form of causal prophylaxis. The minimal infective microfilarial concentration in the blood (after 'Hetrazan' treatment) for *A. pseudoscutellaris* and *A. polynesiensis* has yet to be determined. According to my observations[23] it is about four microfilariæ per 20 c.mm. of blood.

It appears probable that 'species sanitation' against the main vector, as had been practised in Fiji and Rarotonga, and now in Tahiti, promises to be the most effective measure in the ultimate eradication of Pacific filariasis, and that the actual carrying out of repressive measures should be left to specially trained teams of Polynesians.

# OBITUARIES

## Dr. C. S. Hudson

THE death occurred suddenly on December 27, 1952, of Dr. C. S. Hudson at the age of seventy-one, and carbohydrate chemists all over the world mourn the passing of one of their greatest leaders.

Claude Silbert Hudson was born in Atlanta, Georgia, and spent a happy boyhood in Mobile. He entered Princeton University in 1897 in order to study for the Presbyterian ministry. He became so interested in chemistry during his course for the B.S. degree that eventually he decided to become a scientist. After graduation (1901) he was elected into an endowed fellowship in experimental science at Princeton and began an investigation on the mutarotation of milk sugar, under W. F. Magie, then professor of physics. This first investigation, published in 1902 when he was twenty-one, marks the beginning of his brilliant series of more than two hundred and fifty publications on the carbohydrate group.

Hudson's first leanings were towards the physical side of chemistry, and he spent a profitable year with Nernst at Göttingen (1902–3). On returning to the United States he became a research assistant to A. A. Noyes in Boston, and then he held an instructorship in physics at Princeton (1904–5) and at Illinois University (1905–7); after holding several other posts he was appointed chemist to the Bureau of Chemistry at Washington, where he stayed until 1919. He then became a consultant chemist for four years, afterwards joining Frederick J. Bates at the National Bureau of Standards, where he carried out many notable researches up to 1929. In this year he was invited to the professorship of chemistry in the U.S. Public Health Service, where he remained until his retirement at the age of seventy. During his tenure of this latter post he was enabled to secure the assistance of a succession of brilliant young scientists who, inspired by his able leadership, have achieved world-wide distinction.

Among his many great works on carbohydrates, Hudson's contributions to preparative methods and to the relationship between rotatory power and structure stand out, while his famous 'lactone rule' was perhaps his greatest single personal contribution and was one of the most notable landmarks in carbohydrate chemistry. He was a brilliant experimentalist and his writings bear the stamp of a master mind. He infused his passion for the sugars into his many pupils, who bore him great respect and devotion.

In the late 1920's he engaged in a notable controversy with the late Sir Norman Haworth regarding the ring structure of certain of the sugars, and following his eventual acknowledgment of the correctness of Haworth's views the two began a friendship which both greatly treasured. The results of this friendship were seen in the founding of the "Advances in Carbohydrate Chemistry", to which Hudson as the senior editor particularly devoted the last few years of his life and from the guidance of which he will, indeed, be sadly missed. He was largely instrumental also for founding the "Starch Round Table", which provides an annual forum for discussions on this important foodstuff.

Many honours came to him, particularly from the American Chemical Society. He received the Borden Medal and Award (1941), the Nichols Medal of the

New York Section (1916), the Willard Gibbs Medal of the Chicago Section (1929), the Richards Medal of the North-Eastern Section (1940) and the Hillebrand Prize of the Washington Section in 1931, etc. He was a member of the National Academy of Sciences, and the Chemical Society in London elected him to honorary fellowship. He received the major share of the Sugar Research Foundation Grand Award in 1950.

Hudson loved life and lived it to the full. He was a delightful companion with an inexhaustible fund of 'true' stories, and he engaged the affection of all who knew and admired his wisdom. He is survived by his wife (Erin Gilmer) and by two married daughters. M. STACEY

## Prof. C. J. Hawkes, O.B.E.

CHARLES JOHN HAWKES commenced his professional career in the engine rooms of the Navy, and from there, in 1912, he became joint secretary of the Royal Commission on Fuel and Engines under the chairmanship of Admiral of the Fleet Lord Fisher. Thenceforward, Commander Hawkes was in the forefront of naval research at a crucial period in naval history, and as the first superintendent of the Admiralty Engineering Laboratory he did much to develop the heavy-oil engine for submarines.

His reputation as a leading authority on the heavy-oil engine accompanied him when, in 1920, he was appointed professor of mechanical, marine and civil engineering in the University of Durham. His work at King's College, Newcastle upon Tyne, was paralleled by his zealous participation in the activities of the North East Coast Institution of Engineers and Shipbuilders. Of this important body he eventually became president, gold medallist and honorary fellow, and his papers, including the fourth Andrew Laing Lecture, were outstanding contributions to the Institution's *Transactions*. Prof. Hawkes's work was well known abroad and his knowledge of his subject won the regard of many engineering bodies. He was elected an honorary member of the American Society of Naval Architects and Marine Engineers, and, in 1938, had the unusual experience of making an after-dinner speech by radio on the occasion of the Society's annual dinner in New York. His research was not confined to heavy-oil engines. In Newcastle upon Tyne he inspired and superintended university research and served on the Heat Engines Trial Committee of the Institution of Civil Engineers, of which he was a full member. Insistent always on the importance of practical training as a basis for academic studies, he underlined this belief by distinguished work on the Board of Trade Departmental Committee on Marine Engineers' Certificates, for which service he was awarded the O.B.E.

To the younger generation of engineers and to his university colleagues in Newcastle upon Tyne, Hawkes will be remembered for his buoyant and witty spirit, and for his sincere interest in the good of his students and mechanics. He was always approachable and was as much at home, and greeted with as much affection, in the workshops as in the lecture theatre. His rich store of naval anecdotes, through many of which he recalled his work under Admiral Fisher, are still remembered along Tyneside. Though coming relatively late to university work, he did much on Faculty and Senate to raise standards, and it fell largely to his credit that Armstrong College was well known as a centre of progressive engineering education. Prof. Hawkes helped to carry the College through to its new status of King's College, and it was for his valuable work over a period of twenty-six years that the University of Durham conferred on him the title of emeritus professor, and the honorary degree of doctor of science. His death on January 30 at the age of seventy-two represents a loss to his many friends on Tyneside, and to the related spheres of engineering and education.

W. FISHER CASSIE

## Prof. Nathan Banks

PROF. NATHAN BANKS, emeritus curator of insects in the Museum of Comparative Zoology, Harvard University, died on January 24 at the age of eighty-four. Prof. Banks was born at Roslyn, N.Y., on April 13, 1868. He received a B.S. degree from Cornell University in 1889 and an M.S. from the same University in 1890. He was employed by the Division of Entomology, U.S. Department of Agriculture, during 1890–1916. In 1916 he was appointed curator of insects in the Museum of Comparative Zoology, Harvard University, a post which he held until 1944. Banks was one of the best-known entomologists of his time. He published extensively on Neuroptera and other orders of insects and also on spiders, and he built up and maintained in the Museum of Comparative Zoology at Harvard one of the finest collections of insects in America. He is noted also for his bibliographical work on the literature of insects. We, his associates at the Museum of Comparative Zoology, feel his loss very deeply.

P. J. DARLINGTON, JUN.

## Mr. Rhys Jenkins

WITH the death at Hastings on January 27 of Rhys Jenkins, the engineering world loses its oldest and its foremost historian. Born so long ago as September 29, 1859, in the village of Mountain Ash, Glamorganshire, Jenkins served an apprenticeship in the engineering works of Richard Nevill at Llanelly and then was a draughtsman in well-known works in Leeds, Grantham and Gainsborough; in 1884 he joined the examining staff of the Patent Office, from which he retired as a senior examiner in 1920 after thirty-six years service. He had joined the Institution of Mechanical Engineers in 1880 and had therefore been a member for more than seventy years.

Immersed as he was at the Patent Office in the history of inventions, he devoted his leisure to the systematic study of a great variety of industries, visiting many localities, collating material from manuscripts, local histories, State records and the like, and thus amassed a wealth of information which was critically examined and arranged. His first work of note was his book "Power Locomotion on the Highway" (1896), followed six years later by his "Application of Mechanical Power to Road Vehicles" —a mine of information for researchers. These were followed by a succession of historical surveys published in the technical press and various journals.

With other engineers and students of engineering history, he attended the Watt centenary celebrations at Birmingham in 1919, and on the formation next year of the Newcomen Society for furthering the study of the history of engineering and technology, became one of its most active members and served as president during 1924–25. He enriched its *Transactions* with paper after paper, dealing with such matters as the iron industry, the steam engine, fire engines, the work of Savery, Newcomen, Jonathan Hornblower, Arthur Wolff, and others. At nearly every summer meeting of the Society in its earlier days he was able to review the industries of the district visited. A major work was his "James Watt and the Steam Engine" (1927), written in collaboration with the late Dr. H. W. Dickinson. The esteem with which he was held by his fellow members was shown by the re-publication by the Council in 1936 of his miscellaneous papers which had appeared before 1920.

E. C. Smith

We regret to announce the following deaths:

Father A. Gatterer, *S.J.*, director of the Astrophysical Laboratory, Specola Vaticana, Castel Gandolfo, on February 17, aged sixty-seven.

Prof. Justin Jolly, professor of histophysiology in the Collège de France and *académicien libre* of the Paris Academy of Sciences, on February 1, aged eighty-two.

Prof. N. A. V. Piercy, professor of aeronautical engineering in the University of London (Queen Mary College), on February 1, aged sixty-one.

# NEWS and VIEWS

## Botany at Oxford:

### Prof. T. G. B. Osborn

Prof. T. G. B. Osborn, who has been Sherardian professor of botany in the University of Oxford since 1937, is retiring from that chair. He went to Oxford from the University of Sydney, Australia, where his researches in the ecology of natural and semi-natural vegetation laid a firm foundation for later work. Under his guidance the Department of Botany remained happy during a period when botany in Oxford was expanding in the cramped surroundings of the old building. It was owing to his initiative that the Department moved to the new laboratory in the Museum, and there close co-operation with the Botanic Gardens, first begun by him, is still maintained. Indeed the great improvements in the Gardens which have occurred in recent years owe much to his expert supervision and advice. Prof. Osborn has been active in University business and, especially during the War, in advisory work for the Agricultural Research Council and other public bodies. These calls upon his time and especially those associated with the design of the new laboratory were so great that his own researches inevitably suffered. The solid achievement of causing the new laboratory to be built will be found, perhaps, to be a greater contribution to botany than any series of laboratory experiments. Oxford will regret the departure of a professor who has advised and guided his colleagues with tact and forbearance.

### Prof. C. D. Darlington, F.R.S.

Prof. C. D. Darlington, who is to succeed Prof. T. G. B. Osborn, was born in 1903 and educated at St. Paul's School and Wye College. On graduating he joined the staff of the John Innes Horticultural Institution, of which William Bateson was then director. A year or so earlier Bateson had returned from a visit to the United States, where he had seen evidence which convinced him that the proper study of genetics required also study of the chromosomes. He then appointed W. C. F. Newton to his staff as a cytologist, and when Darlington went to the Institution he also joined in this new line of work. Newton's early death in 1927 put an end to their collaboration and left Darlington to continue, at first virtually alone. Soon aided, however, by a growing body of research students he then began that remarkable series of advances which turned cytology from a descriptive into an analytical study, with its own principles, and taking its place as an essential part of the greater structure of genetical science. The new cytology was expounded in the now famous "Recent Advances in Cytology", and it reached its zenith with the smaller though no less important book "The Evolution of Genetic Systems", which discussed and presented the chromosome mechanism, in all its great variety of forms, as the product of evolution by natural selection.

During this period Darlington had been appointed first head of the Cytology Department and later, when Sir Daniel Hall retired in 1939, director of the 'John Innes'. He saw the Institution through the difficult period of the War, during which the old buildings at Merton suffered serious damage, and then through its removal to a new and very much larger home at Bayfordbury. He was elected to the Royal Society in 1941 and received a Royal Medal in 1946. At the same time his interests extended to cover genetics as an even wider discipline, well exemplified by his writings on cytoplasmic heredity, viruses and cancer which he presented as part of the broader picture in which heredity, development and infection were all joined together for the first time. Prof. Darlington takes a wide knowledge and understanding of plants, horticultural as well as botanical, to his new appointment at Oxford, which will provide opportunity for presenting, in a broader field, genetical science as the firm base from which so much in modern biology can be seen to spring.

## Society for Visiting Scientists

Prof. A. V. Hill and Sir Harold Spencer Jones, president and past-president respectively of the Society for Visiting Scientists, have issued an appeal for funds to enable the Society not only to extend but even to maintain its activities. In 1944, when many Allied scientists were working in Britain, the Society was established in London, on the initiative of the British Council and in consultation with the Royal Society, as a centre where overseas and British scientists could meet. The Society has expanded rapidly; it has become widely known abroad, and considerable goodwill towards science in Britain has been built up and fostered through its 1,730 overseas members—a number which is constantly increasing. It enjoys the esteem and encouragement of organized international science, as represented by Unesco and the International Scientific Unions, as well as of Government science in Britain and of many learned societies. It is on friendly and co-operative terms with the scientific liaison officers of the Commonwealth countries and with the science representatives of other countries. At the Society's House, there is at the disposal of scientific institutions and of individual scientists a body of information about science and scientists not easily available elsewhere, and this is drawn on by many at home and overseas. The

Overseas Science Students Association, formed in 1952 to welcome postgraduate science students from other countries and to bring them into closer contact with each other and with the scientific life of Britain, has its home in the premises of the Society for Visiting Scientists. The Society's financial resources were hitherto derived mainly from an annual grant of £4,000 from the British Council. The recent reduction in the Government's grant to the British Council as a whole has forced the Council to halve its annual grant to the Society. To enable the Society to function efficiently, at least £6,000 per annum is required; it is therefore necessary to raise an annual sum of £4,000. It is hoped that much of this sum will be contributed by corporations and individuals through deeds of covenant, though other subscriptions will, of course, be welcomed. Inquiries should be sent to the Honorary Treasurer, Society for Visiting Scientists, 5 Old Burlington Street, London, W.1.

### Flamsteed's Observatory

Treasury approval has been given to a scheme, proposed initially by the Astronomer Royal, under which the historic buildings of the Royal Observatory at Greenwich will be taken over, as they are vacated by the removal of the Observatory to Herstmonceux, by the National Maritime Museum. These include, the original building, designed by Sir Christopher Wren, and built in 1675, containing the Octagon Room (the observatory of the first Astronomer Royal, the Rev. John Flamsteed), and the various additions made during the eighteenth century. The historic instruments, which have played so large a part in the progress of fundamental astronomy, will remain at Greenwich. They include Halley's transit instrument—the first transit instrument to be used in England; the zenith sector, with which Bradley discovered the aberration of light and the nutation of the earth's axis; and the Airy transit circle, installed in 1851, which by international agreement defines the zero of longitude. It is the intention of the director of the National Maritime Museum to move a portion of the exhibits relating to navigation from the main museum to the Observatory, which will become an Annexe of Astronomy and Navigation. This is peculiarly appropriate, as the Royal Observatory at Greenwich was established by Charles II in the interests of navigation. The Wren building, which suffered damage during the War, has been repaired by the Ministry of Works and restored as nearly as possible to its original appearance. It is expected that the Octagon Room will be opened to the public about the beginning of May. The Shepherd 24-hr. electric clock, outside the main gate, which is an object of interest to visitors, will remain in position. The custom of dropping the time-ball at 13.00 hr. each day has been resumed: the time-ball was installed in 1833 and provided the first public time-signal in Great Britain.

### Agriculture in the United States

During the years 1945–50 Mr. A. N. Duckham, then agricultural attaché to the British Embassy in Washington, travelled all over the United States, gaining an insight into the methods of farming in each of the forty-eight States he visited. An interesting account of his experiences is given in an illustrated booklet entitled "American Agriculture: its Background and its Lessons" (pp. 78+4 pl.; London: H.M.S.O., 1952; 2*s*. 6*d*. net). The chief objects of this report are to provide the necessary technical and commercial background for a proper understanding of farming methods in the United States, and to point out features of their agriculture which may hold positive (or negative) lessons of potential value to the British farmer. The subject is dealt with from four main aspects—geographical and social background; rural organization and agricultural services; production techniques; and farm organization and labour economy—while maps and statistics giving crop acreages and yields, number of livestock and machines, etc., are included in an appendix. Throughout the report it is abundantly clear how differences in soils and climate, natural resources, land-tenure systems and social background have influenced the development of agriculture in the two countries of Great Britain and the United States, and that in general no direct comparison can be made between their farming practices. Nevertheless, Mr. Duckham appears to regard the human element as the chief cause for present-day differences, the British farmer taking a special pride in good husbandry, whereas his American counterpart attaches more weight to efficient organization and labour economy. Each, he maintains, has something to learn from the other, and, if this were achieved, rural standards on both sides of the Atlantic would be raised.

### Rabbit Problem in Gotland Island

In Bulletin No. 9 of the Royal School of Forestry. Stockholm (Stockholm: Kungl. Skogshögskolan, 1952; 5 kr.), G. Notini and S. Forselius discuss the methods which have been undertaken to exterminate the wild rabbits on Gotland Island. The wild rabbit was introduced into Sweden with the object of providing a new game animal of commercial value. Vigorous stock was selected and care was taken to ensure the proper environmental conditions, based on European accumulated experience in parts where the stock had become more or less stabilized, excess numbers being kept down by small predatory animals and also disease. As has occurred in other parts of the world where mammals, birds and plants have been introduced outside their own habitat, the rabbits in Gotland increased rapidly in numbers. None of their ordinary checks was present, the only one being the occasional severe winters experienced in the island. The ordinary methods of man—shooting, poisoning, snaring, etc.—but not poison, have proved ineffective; poison is regarded as too dangerous. The rabbit problem has therefore been transferred from the Game Department to the domain of rural economics. The rabbit to-day in Gotland constitutes such a menace to sylviculture and agriculture that it is ranked with the small rodents. Work is now being undertaken on the introduction of the virus disease *Myxomatosis cuniculi* into the Gotland rabbit population. These trials are on similar lines to those already in operation in Australia, where considerable success has already been reported (see *Nature*, 170, 7; 1952), and it will be interesting to see how the results in the two different hemispheres will eventually compare.

### Problems in the Calculation of Interplanetary Orbits

In a paper on "Interplanetary Orbits" (*J. Brit. Interplanetary Soc.*, 11, No. 5, September 1952), J. G. Porter points out two fundamental errors in dealing with interplanetary travel (the discussion being limited almost entirely to the earth–moon system) which should be noted by all serious students of astronautics. First, although computers use seven-figure tables, probably only five figures are trustworthy, because the co-ordinates of the sun and planets are doubtful beyond five decimal places in astronomical units, and in consequence of this considerable errors in miles or kilometres are inevitable in many of the calculations. The second possible source of error arises from the fact that the movements of the bodies in our solar system may not be amenable to accurate treatment by the old classical mechanics. Porter gives a number of instances where important factors have been more or less ignored in the computations. For example, some have asserted that it would be economical to send a space ship to the neutral point between the earth and the moon, this point being about 24,000 miles from the moon, and then to allow it to fall relatively slowly towards the moon. But, as Porter points out, the attraction of the sun is nearly double that of the earth or the moon at the neutral point, and this would control the ship, which would then describe an orbit about the sun. Even if the supposed possibilities regarding the neutral point are completely excluded from consideration, difficulties of a serious nature would arise in other ways.

If it is decided to travel to the moon in an elliptical orbit, the speed of approach to the moon will be so high that a large amount of fuel must be used in braking (in the paper some figures are given on this matter) and, instead of travelling in an elliptical orbit for nearly five days to reach the moon, it would be as efficient to travel in a parabolic orbit which would require a little more than two days. Another difficulty arises if a ship is perturbed by some other body because, though there may be a small increase in the acceleration, nevertheless when this has ceased the velocity increase remains and the effect on the distances can be very great. All this demands that the initial conditions of velocity, distance, and angle of projection of the ship should be accurately determined; but even with the greatest accuracy, occasions will arise when pre-computed orbits will require modification. How such modifications could be computed during flight may present serious problems to future interplanetary navigators.

## Temperature of the Chromosphere

A PAPER by Shotaro Miyamoto on the "Kinetic Theory of the Chromosphere" (*Pub. Astro. Soc. Japan*, 3, No. 2 (1951), and also *Contrib. Inst. Astrophys., Kyoto Univ.*, No. 17) examines all the available data regarding the temperature of about 30,000° C. of the corona, and points out the difficulties of accepting this high temperature. Redman derived it from the contour observation of the chromosphere emission lines at the eclipse of October 1, 1940 (his results appearing in *Mon. Not. Roy. Astro. Soc.*, 102, 140; 1942); but Miyamoto gives a number of reasons for disagreeing with these results. He does not, however, attempt to complete the low-temperature hypothesis, but refers to the paper by Woolley and Allen on "Ultra-Violet Emission from the Chromosphere" (*Mon. Not. Roy. Astro. Soc.*, 110, 358; 1950), which appeared after he had written his paper. Miyamoto claims that they are in general agreement with his low-temperature hypothesis, and, while admitting the anomalous excitation of the chromosphere as an observational fact, he does not accept this as necessarily implying a high kinetic temperature.

## *Journal of the Madras Institute of Technology*

THE Madras Institute of Technology, which is situated at Chromepet, fourteen miles from Madras, was founded in July 1949, and now the first number of its *Journal* has appeared (1, No. 1; August 1952. Rs. 4, 8*s*. or 1 dollar per issue; Rs. 8, 16*s*. or 2 dollars a year), edited by the professor of applied mathematics in the Institute, Dr. A. Narasinga Rao. The Institute was started with a gift of Rs. 500,000 from Sri C. Rajam, a grant of Rs. 500,000 from the Madras State Government and a number of smaller gifts from various organizations and persons. It deals with education and research (pure, applied and sponsored) in the physical sciences, engineering and technology, and until now it appears to have concentrated mainly on the educational side—and rightly so; but the time is fast approaching when the research activities will play an equally important, if not the major, part in the life of the Institute, and it is therefore fitting that the *Journal* should be started, wherein the fruits of new knowledge can be published. The Institute offers courses extending over three years, during the first year of which the students follow for the most part a general course in the basic sciences (mathematics, physics and chemistry) and basic engineering subjects. After that they specialize in one of the four faculties, which are as follows (numbers of second- and third-year students in each faculty being shown in brackets): aeronautical engineering (10, 24), automobile engineering (24, 23), electronics (28, 18), and instrument technology (8, 7). After a short description and faculty notes on the activities of the Institute, the main part of the first number of the *Journal* is devoted to articles as follows: "Aeronautical Science To-day", by Dr. W. Repenthin, head of the Faculty of Engineering of the Institute; "Numerical Calculations in Electrical Engineering and Electronics: Part 1, Calculation of Determinants", by Prof. R. Filipowsky, head of the Electronics Faculty of the Institute; "Oxidation of Hydrocarbons", by Dr. S. V. Anantakrishnan, visiting professor of chemistry in the Institute; "Note on a Method of Transient Analysis", by K. K. Clarke, of the Electrical Engineering Department, University of Ceylon; "On the Kalidasa Effect", by Dr. A. Narasinga Rao; "Introduction to the Giorgi System of Units", by Dr. R. Wallauschek, head of the Faculty of Instrument Technology in the Institute; "Patent: its Law and Practice", by Prof. V. Subramanian, visiting professor of the Institute; and "On a Method of measuring very Small Time Intervals", by A. Suszkin, laboratory research engineer in the Institute. A number of short notes completes the issue.

## *Fusarium* Contamination of Grain

THE prevalence and taxonomy of *Fusarium* species in cereal seed in Canada is considered in detail in a recent paper by W. L. Gordon, of the Dominion Laboratory of Plant Pathology, Winnipeg (*Canad. J. Bot.*, 30, No. 2, 209; 1952). In all, of about four thousand seed samples of wheat, barley and oats which have been examined (a hundred kernels per sample), the statistics show considerably heavier infections in Eastern than in Western samples. A total of sixteen species and varieties of *Fusarium*, classified in nine sections of the genus, was isolated. (The classification used is that of Wollenweber and Reinking, but some sections have been extensively revised in conformity with the views of Snyder and

Hansen.) Detailed diagnoses, line illustrations of conidia and chlamydospores, and some good photographs in colour of monoconidial cultures of the wild type of each species, variety or form are given.

### Chromatography of Phycocyanin

E. C. Wassink and H. W. J. Rageth have reported on a paper chromatographic analysis of the blue solution obtained by the acid hydrolysis of the photosynthetically active chromoprotein, phycocyanin, of the blue-green algæ *Oscillatoria* (*Proc. Koninkl. Nederlandse Akad. van Wetensch.*, Ser. C., LV, 4, 462; 1952). The analysis yielded sixteen amino-compounds of which thirteen were known amino-acids and three were unknown substances, one of these last being present in relatively large amount. Arginine was absent; but otherwise the assay of the *Oscillatoria* phycocyanin did not reveal important differences from the bulk proteins of the green algæ *Chlorella vulgaris* (with chloroplast proteins) or from horse hæmoglobin.

### Blundell's School Science Society

The seventh issue of the Blundell's School Science Society magazine again shows the remarkably fine work being done at boarding schools in Britain in the training of young scientists. One article, for example, describes some studies of the biology of ivy-leaved duckweed (*Lemna trisulca*) by a senior boy, M. J. Corrigan. Among the questions he investigated were methods of encouraging growth, the effect of temperature and the role of auxin on growth, the growth of the plant under different wave-lengths and intensities of light, as well as the reasons which cause *Lemna trisulca* to sink to the bottom of a canal in winter and to cause its fronds to float just below the water-surface at other times. Corrigan's article is supported by two others by boys who, like him, have been awarded school prizes for their original work. The magazine also describes the many meetings held by the Science Society during 1951–52 and the records compiled by individual members and sub-committees of the Society in and around Tiverton. In addition there is an admirable account by two boys of a recent visit to an old but recently resuscitated iron-works at Dunsford.

### Fourteenth International Congress of Zoology, Copenhagen

The Fourteenth International Congress of Zoology will be held in Copenhagen during August 5–12. It has been decided to have a fairly large number of sections, so that comparatively specialized fields can be discussed, and a provisional list of sections (with the name of each organizer) has been arranged as follows: nomenclature (Dr. H. Lemche), invertebrate palæozoology (Prof. Chr. Poulsen), vertebrate palæozoology (Dr. E. Nielsen), quaternary zoology (Dr. M. Degerbøl), zoogeography (Prof. R. Spärck), speciation (Dr. F. Salomonsen), genetics of populations (Dr. H. Lemche), cytology (Dr. H. Holter), sub-microscopical structure of animals (Prof. H. V. Brøndsted), animal regeneration (Prof. H. V. Brøndsted), morphogenesis (Prof. H. V. Brøndsted), animal psychology and ethology (Dr. H. Poulsen), comparative physiology (Prof. P. Brandt Rehberg), parasitology (Prof. M. Christiansen), nematology (Dr. P. Bovien), terrestrial ecology (Dr. Ellinor Bro Larsen), marine ecology (Dr. G. Thorson), entomology (Dr. S. L. Tuxen), vertebrate systematics (Dr. M. Degerbøl) and invertebrate systematics (Dr. P. L. Kramp). Four general meetings have been planned at which lectures lasting about an hour will be given on topics of general interest, followed by discussion. At the section meetings a specialist will be invited to give a lecture lasting about forty minutes, which will cover a central problem of the section concerned; added to this, members may read short papers, not more than twenty minutes in duration, and also give brief demonstrations of animals, slides, films, etc. The official languages of the Congress will be English, French and German. All who wish to contribute to the proceedings or reserve hotel accommodation should communicate with the secretariat before April 15; the last date for membership registration is June 1. All communications should be addressed to the secretariat of the Congress at Krystalgade 27, Copenhagen *K*.

Immediately before the Congress a colloquium, organized by Mr. Francis Hemming, will be held by the International Commission on Zoological Nomenclature, officially representing the International Union of Biological Sciences. During the Congress a colloquium will be held on "Zoogeographical Problems of the Deep-Sea Fauna", organized by Prof. R. Spärck.

### Rumford Bicentenary Celebrations in the United States

The bicentenary of the birth of Benjamin Thompson, Count Rumford, on March 26, 1753, will be celebrated in the United States at Boston, during March 26–28, by the American Academy of Arts and Sciences. The social functions in the celebrations will be a dinner on March 26, at which Sanborn C. Brown, of the Massachusetts Institute of Technology, will give an account of his researches into the life of Rumford, and on March 27 a ceremony will be held at which Rumford Medals of the Academy will be presented to Profs. E. Fermi, W. E. Lamb, jun., and L. Onsager. In addition, during the morning and afternoon of March 27 and the morning of March 28, respectively, the following three symposia will be held, at which the speakers will be as shown: recent developments in thermodynamics (Prof. P. W. Bridgman, Harvard; Sir Alfred Egerton, London; Prof. L. Onsager, Yale; and Prof. F. E. Simon, Oxford); recent developments in atomic spectroscopy (Dr. M. Deutsch, Massachusetts Institute; Prof. W. E. Lamb, jun., Stanford; Dr. E. M. Purcell, Harvard; and Prof. I. I. Rabi, Columbia); and recent developments in nuclear physics (Prof. E. Fermi, Chicago; Prof. J. R. Oppenheimer, Institute for Advanced Research, Princeton; Prof. M. Siegbahn, Nobel Institute, Stockholm; and Prof. V. F. Weisskopf, Massachusetts Institute).

### The Night Sky in March

New moon occurs on March 15d. 11h. 05m., U.T., and full moon on March 30d. 12h. 55m. The following conjunctions with the moon take place: March 4d. 23h., Saturn 8° N.; March 17d. 20h., Venus 2° N.; March 17d. 20h., Mars 5° S.; March 19d. 06h., Jupiter 6° S. In addition to these conjunctions with the moon, Venus is in conjunction with Mars on March 17d. 23h., Venus being 7° N. Mercury sets at 19h. 20m. at the beginning of the month, but draws closer to the sun and is in inferior conjunction on March 18, after which it becomes a morning star, being, however, too close to the sun for observation during the remainder of the month. Venus, an evening star, sets at 21h. 55m., 21h. 45m. and

20h. 50m. at the beginning, middle and end of the month, respectively, and is conspicuous in the western sky for some time after sunset. The visible portion of the illuminated disk varies between 0·332 and 0·070 and the stellar magnitude averages about – 4·2, the greatest brilliancy (magnitude – 4·3) being attained on March 8. Mars is visible in the early part of the night, and sets at 20h. 55m. approximately throughout the month. About the middle of the month it is a little north of ο Piscium, and later it moves into the constellation of Aries. Jupiter sets at 23h. 35m., 23h. 20m. and 22h. 15m. on March 1, 15 and 31, respectively, and lies a little south of δ Arietis during the greater part of the month. Saturn rises at 21h. 50m., 20h. 50m. and 19h. 35m. at the beginning, middle and end of the month, respectively, its stellar magnitude being 0·6, and lies a little north-east of Spica. Occultations of stars brighter than magnitude 6 are as follows, observations being made at Greenwich: March 19d. 21h. 15·9m., 16 Taur. (*D*); March 19d. 21h. 23·5m., 17 Taur. (*D*); March 19d. 21h. 34·6m., *q* Taur. (*D*); March 19d. 21h. 42·9m., 20 Taur. (*D*); March 19d. 22h. 03·1m., 21 Taur. (*D*); March 19d. 22h. 34·0m., η Taur. (*D*); March 22d. 23h. 50·6m., ε Gemi. (*D*); March 23d. 0h. 48·0m., ε Gemi. (*R*); March 26d. 0h. 53·4m., π Canc. (*D*). *R* and *D* refer to reappearance and disappearance, respectively. Vernal equinox occurs on March 20d. 22h.

## Announcements

MR. DONALD W. HUDSON, chairman of the National Pharmaceutical Union and a member of the Council of the Pharmaceutical Society, has been appointed an Officier de l'Ordre de la Santé Publique in recognition of his services as chairman of the Franco-British Pharmaceutical Commission.

MR. H. TREFOR JONES, deputy provincial director, Yorks and Lancs Province of the National Agricultural Advisory Service, has been appointed provincial director of the Province in succession to the late Mr. D. H. Findlay.

MR. J. RANNIE, welding engineer to John Brown and Co., Ltd., of Clydebank, has been awarded the William J. Larke Medal for 1952 of the Institute of Welding for his paper "Shipyard Changes with special reference to Steelwork Construction in Oil Tankers".

DR. C. M. WHITTAKER, an honorary fellow of the Textile Institute and former director of Courtaulds, Ltd., will deliver the Mather Lecture for 1953 of the Institute, following the annual general meeting at the University of Bristol on April 29. Dr. Whittaker will speak on "Common Sense on Colour in Textiles".

THE Institute of Metals has awarded the 1952 W. H. A. Robertson Medal and a premium of fifty guineas to Mr. J. F. Waight, an engineer of the West Midlands Gas Board, for his paper on "Gas Equipment for the Thermal Treatment of Non-Ferrous Metals and Alloys" (*J. Inst. Metals*, 80, 269; 1952). This Medal, which was given by W. H. A. Robertson and Co., Ltd., is awarded annually for the encouragement of the writing and publication in the Institute's *Journal* of papers on engineering aspects of non-ferrous metallurgy.

TRINITY COLLEGE, Cambridge, is offering as in former years a number of research studentships and Dominion and Colonial exhibitions, which will be tenable from next October. The research studentships, which will not exceed £375 a year for a maximum of three years, are open to graduates of universities other than Cambridge (non-graduates of exceptional ability will be considered) who are not more than twenty-six years of age (although time spent in national service may be deducted) and who have not already spent more than two years on advanced study or research. The exhibitions are for students from the British Dominions and Colonies who intend to read for an honours degree, and are worth £40 a year. Applications, to be sent through the head of the candidate's university, must reach the Senior Tutor, Trinity College, Cambridge, not later than May 1.

THE Massachusetts Institute of Technology is offering a number of graduate and advanced research fellowships for study and research in the field of electronics. Graduate student fellowships are for work leading to advanced degrees in physics or electrical engineering and are worth 1,500–2,400 dollars a year; advanced research fellowships, which are worth upwards of 3,000 dollars a year, are for those possessing a Ph.D. degree or its equivalent who wish to pursue advanced studies and research in the field of electronics at the Institute. Applications for these two classes of fellowships should be made to the Director, Research Laboratory of Electronics, Massachusetts Institute of Technology, Cambridge, Mass., at least four months prior to the intended date of entrance. A limited number of positions are also available for students to work as research assistants in the Research Laboratory of Electronics while at the same time pursuing a graduate programme of studies on a part-time basis; further information regarding this scheme can be obtained from the Director of the Laboratory.

A FULL-DAY conference will be held by the Northern Branch of Aslib on March 12 in the Council Chamber of the Town Hall, Stoke on Trent, under the chairmanship of Colonel G. A. Wade, chairman and managing director of the Wade Group of Potteries. Four lectures will be given as follows: the Iron Library, by W. B. Ingram (Britannia Iron and Steel Works, Ltd., Bedford); the British Ceramic Research Association Information Department, by A. E. Dodd (British Ceramic Research Association); historic pottery, by G. I. V. Bemrose (curator, Stoke on Trent Public Museum); and Aslib, what it is and what it does, by Leslie Wilson (director of Aslib). The fee for the conference is 3*s*. 6*d*. Visits have been arranged to various firms and institutions on March 13. Further information can be obtained from Dr. J. C. Withers, "Penmere", 11 Highfield Park, Heaton Mersey, Stockport.

A REPORT of the proceedings of the British Commonwealth Scientific Conference, held in Australia, February–March 1952 (see *Nature*, 169, 856; 1952), has now been published. Besides the opening address of the Prime Minister of Australia and Sir Ben Lockspeiser's reply, and the preliminary statement by the chairman, Dr. I. Clunies Ross, it includes the recommendations and resolutions of the Conference and the text of a statement on the national organization of research adopted by the Conference in full session. Appended are a list of committees and their composition and a summary of action taken on resolutions of the British Commonwealth Scientific Official Conference, 1946.

# PROTECTION FROM THE EFFECTS OF RADIATION

RADIATION protection was the subject for discussion at a joint meeting of the Industrial Radiology Group of the Institute of Physics and the Hospital Physicists Association, which was held at the Royal Institution, London, during January 16–17. From the papers given by the various speakers one could piece together the past history of this subject and the present quickening interest in it.

Dr. L. H. S. Clark described the service which had been established nearly twenty years ago at the Lambeth Hospital to ensure adequate protection of the staff of the radiological departments. Film badges of fast dental film were found satisfactory as means for measuring the doses of X-rays received by the individual in the course of his work. This was no isolated instance of the growing awareness of the need for protection against the damaging effects of ionizing radiation. Tribute was paid to the splendid work of the British X-ray and Radium Protection Committee which, from its inception under the chairmanship of the late Sir Humphry Rolleston and often without financial support, did heroic pioneer work.

Although many individual hospitals or groups of hospitals were taking steps to protect their staff, this was not universally so, and in 1942, as a result of the efforts of the late Dr. A. E. Barclay, it was deemed necessary to have an external monitoring service for those institutions in the Emergency Medical Service where no internal service was maintained. Mr. E. E. Smith described how the National Physical Laboratory was asked to undertake this office and how it solved the problem. Although the degree of blackening of film is dependent on the quality of the radiation applied, nevertheless it was chosen at that time because the available ionization chambers were fragile and liable to misuse. Moreover, with a service conducted by correspondence, the methods had to be as simple as possible. From small beginnings with the receipt of a few hundred films a month, the service supplied by the National Physical Laboratory has steadily progressed. Workers in factories and research laboratories were soon added to the list of customers, and an inspection service was set up to advise those bodies whose workers consistently recorded high doses. Now, about five thousand films a month are processed by five technicians, and happily the proportion of recorded doses above tolerance is steadily diminishing.

These early theoretical and practical aspects were by no means confined to Great Britain. An International Protection Commission had met on several occasions and reported its recommendations; it still continues to do so, the last meeting being in 1950. Dr. J. F. Loutit recalled some medical and biological evidence of the damaging actions of ionizing radiations which the Commission has taken into account in formulating its latest recommendations on permissible doses. It has rightly been chiefly swayed by the medical evidence where man rather than the experimental animal has suffered and even died from excessive exposure. Mr. W. Binks, himself a prominent member of the Commission, also stressed the delayed action of these effects, but appealed for a balanced approach to the problem. Respect, but not fear, on one hand, or foolhardiness, on the other, is to be encouraged, and then this hazard like others can be controlled. He quoted the figures of permissible doses of the various types of radiation so far considered. As regards penetrating radiation, he issued a note of warning that many of the published tables of transmission through lead and concrete are out of date in that narrow beams only are considered. Nowadays broad beams are more frequently in operation, and the transmissions here are vastly greater. Mr. Binks appealed for still more effort in investigating the fundamental biological action of radiation and the early incorporation of new knowledge into codes of practice. He hoped that these wishes would be implemented by a new national protection organization established jointly by the Medical Research Council and Ministry of Health.

The most modern methods of measurement of dose by means of films were reviewed by Dr. G. Spiegler. It is necessary to measure, on one hand, the hard gamma-ray radiation of radioactive isotopes and, on the other, the relatively soft emissions of diagnostic X-ray machines or the scattered rays from radioactive sources. Thus the monitoring film contains an exposed portion to record the combined soft and hard radiation and a portion or portions protected by aluminium, brass, lead, cadmium or other appropriate filter to measure the harder components. By contrast, with very hard rays of energy greater than 2 MeV., there is a reversal of the usual picture and less blackening of the unfiltered area.

Whereas X-ray film is still the main standby for the measurement of dose, ionization chambers also play their part. Dr. E. Dyson described some of those in use at the Atomic Energy Research Establishment, Harwell. Large ion-chambers are used for area monitoring; but by themselves they would be inadequate because of the variation in scattering under altering conditions. The personal dosemeter is a necessary addition. For specific purposes this can be either a condenser-type chamber which is charged and after use read by various electrometers, or a quartz-fibre electrometer which the wearer can himself read and assess the rate of accumulation of dose. With radiation of 100 keV. and more, the variation of the reading with hardness of the rays is of the order of ± 10 per cent. These electrometers are somewhat sensitive to hard beta-rays.

As modern research and development makes available X-rays of greater and greater energy and radioactive sources of greater activity, industry is finding increasing use for them, particularly in engineering for testing purposes. Dr. C. Sykes noted that, while each source is obtained for a specific purpose, the applications multiply. The increasing time and scope of use of these sources make the originally devised protective arrangements inadequate. If the job is brought to the source, protection should not be difficult; but when the source is taken to the job, it is not simple to give adequate protection without disturbing the normal routine of the workshop. This increasing use, particularly of radioactive isotopes, by firms with no previous experience of the subject and therefore no competent medical officer or physicist, exposes the need for a set of rules clear even for factory managements.

Dr. H. Harris (Babcock and Wilcox, Ltd.) and Dr. J. S. Blair (Stewart and Lloyds, Ltd.) carried the discussion further from the point of view of industry.

In their experience the literature on protection is not readily available; but a competent engineer can solve his problems by common sense and by insisting on a rigid discipline among the operating staff.

The legal responsibility for the health and welfare of workers in factories, but not in research laboratories, lies with the Ministry of Labour. Mr. K. Goodall (H.M. inspectorate of factories) described how this Ministry watches for new hazards and advises on old ones. In the case of sealed sources of radioactive isotopes, the position is at present satisfactory in that the Ministry is informed from Harwell or Amersham of the delivery of all such consignments to new customers. Present records show surprisingly few accidents, and Dr. Ethel Browning's hæmatological data contain few abnormalities. With the existing policy of persuasion, results are as satisfactory as would be expected if regulations were in force; the greatest danger, said Mr. Goodall, still remains not the closed sources of radioactivity but the open sources met with in the luminizing industry.

In industry, according to the evidence presented, the care or discipline exercised has resulted in the workers receiving doses well below tolerance (an average of about 10 mr./week in one case). By contrast, in the Ordnance Inspectorate of the Royal Navy, as it appeared from Commander P. Chandler's remarks at the meeting, policy is determined by the delivery of the goods and not by the hazard to the staff. This attitude may be necessary in the Armed Forces in time of war, but was alarming to the medical section of the audience.

---

# ROYAL ASTRONOMICAL SOCIETY

## PRESENTATION OF GOLD MEDAL

At the meeting of the Royal Astronomical Society on February 8, 1952, at Burlington House, London, the Gold Medal of the Society was presented to Dr. John Jackson by Prof. H. Dingle, the president of the Society, who gave an address which has since been published in full (*Mon. Not. Roy. Astro. Soc.*, 112, 3; 1952).

Not very long after Dr. Jackson had finished his career at Cambridge he went, in 1914, as chief assistant to the Royal Observatory, Greenwich, where about twenty years of work on double stars with the 28-in. refractor awaited analysis, and this task was undertaken by Jackson in collaboration with Furner. There were also available F. G. W. Struve's results, published in 1837, which included 3,112 close pairs, and many more were added by the late Otto Struve, who continued his father's work. Jackson showed that 649 of F. G. W. Struve's stars had changed their configuration since his day; of these, 449 showed true orbital motion, 161 were optical doubles the components of which differed in proper motion, and in 39 the nature of the motion was uncertain. Among Otto Struve's stars he found that 135 were binaries, 15 optical doubles and 5 had doubtful motion. The results of the analysis were published in a number of papers in *Monthly Notices of the Royal Astronomical Society* from 1920 onwards, and the hypothetical parallaxes deduced agreed well with the trigonometric and spectroscopic parallaxes which were then available. The next step was the determination of the cross-components of the velocities of the stars from their known proper motions, from which the apex and speed of the solar motion were determined, and these showed good agreement with those found by other methods. The absolute magnitudes of the stars were also determined from their apparent magnitudes, and this provided further evidence for the separation of the stars of the later spectral type into giants and dwarfs, which had been investigated by Hertzsprung and Russell some years previously and gave strong support to Russell's theory of stellar evolution.

During 1924–30 Jackson carried out valuable work on time measurement. Two Shortt free-pendulum clocks, the running of which was in charge of W. Bowyer, acting under Jackson's direction, were installed at the Royal Observatory in 1924 and 1926, and four papers on their behaviour up to the end of 1930 appeared in the *Monthly Notices*. An analysis of the errors showed that these could be reduced to three terms, one due to nutation causing non-uniformity of sidereal time, another arising from temperature fluctuations, and the third—the 'secular term'—the origin of which was not immediately obvious but which was later attributed to a gradual increase in the length of the invar rod of the free pendulum. Other possible causes, however, were conceivable, and subsequent observations cast doubts on the supposition that the gradual growth of the invar rod was the main cause of the secular term. The conclusion was that the most that could be hoped from these clocks in detecting fluctuations in the earth's rotation was that they might determine whether erratic changes of 1·0″ a year in the moon's longitude could be due to irregularities in the earth's rotation period. One very valuable result of the whole investigation was the discovery of the nutation effect, showing the necessity for distinguishing between apparent and mean sidereal time.

In 1930 Jackson published an analysis of observations made with the Greenwich Cookson zenith telescope; this indicated that the value of the constant of nutation was 9·2066″ ± 0·0055″, which was smaller than the value used in the ephemerides. The latter, based on Newcomb's determination from a very long series of observations, agreed very well with a more recent determination by Przybyllok, and a discordance between this and the theoretical value, considerably larger than the probable error, requires some explanation. Jackson regarded it as "one of the outstanding discordances of the constants of the solar system"; but, as Prof. Dingle remarked in his address, it is unlikely that the last word has yet been said concerning the theoretical value.

In 1925 Jackson began to collaborate with Knox-Shaw and Robinson, of the Radcliffe Observatory, Oxford, on the reduction of Hornsby's meridian observations. The observations selected for reduction were those made between 1774 and 1798, and included about 43,000 observations of stars, 5,200 of the sun, 4,600 of planets, and 1,200 of the moon. From the results it was possible to apply systematic corrections to Boss's "Catalogue" and also to Newcomb's tables of the sun's longitude, and to other elements of the sun's apparent orbit about the earth—the equinox, the obliquity, the eccentricity and the longitude of perigee. The main publication appeared in 1932 and was followed with a paper in the *Monthly Notices* on the observations of Mercury; these observations were specially important in checking the motion of the planet's perihelion.

In 1933 Dr. Jackson succeeded Sir Harold Spencer Jones as His Majesty's Astronomer at the Cape of Good Hope, and until his retirement in 1950 his work there followed the main lines laid down by his predecessor. The programme consisted of three parts: the parallax work, the determination of positions and proper motions of stars in the Cape astrographical zones, and the compilation of a "Photographic Zone Catalogue" for the region $-30^\circ$ to $-90^\circ$ in declination. Spencer Jones's programme, inaugurated in 1926, was the measurement of the parallaxes of all possible stars of proper motion exceeding $40''$ a century south of declination $-10^\circ$. Although a number of determinations had been made when Jackson assumed office, the greater part of the programme remained to be executed, and results were published from time to time in the *Monthly Notices* and in three successive volumes of the *Cape Annals*, which were edited by Jackson. In his annual report for 1949 Jackson announced that 1,623 parallaxes had been determined since the work started and that it was then almost completed. The results of the second part of the programme were published in 1936 under the titles "Proper Motions of Stars in the Zone Catalogue of 20,843 Stars, 1900, Zones $-40^\circ$ to $-52^\circ$, derived from the Photographs taken at the Royal Observatory, Cape of Good Hope", and in 1939 in "Catalogue of 20,554 Faint Stars in the Cape Astrographic Zone $-40^\circ$ to $-52^\circ$, for the Equinox of 1900·0, giving Positions, Precessions, Proper Motions and Photographic Magnitudes, derived from Photographs taken at the Royal Observatory, Cape of Good Hope". Many important statistical results were derived from this study of more than forty thousand southern stars, and the information obtained has an important significance for the future. Good progress has also been made on the third part of the programme, the compilation of a "Photographic Zone Catalogue" for the region $-30^\circ$ to $-60^\circ$ in declination, with the wide-angle cameras, in which programme magnitudes and colours have also been included.

Prof. Dingle referred also in his address to a number of other tasks which Dr. Jackson has undertaken at the Cape; but it is sufficient in this résumé to quote Prof. Dingle's words that "The Gold Medal of our Society is bestowed for outstanding excellence of astronomical work, and for nothing else".

# BRITISH DEPENDENCIES IN THE CARIBBEAN AND NORTH ATLANTIC

PROF. W. M. MACMILLAN'S "Warning from the West Indies" was published in 1936: the 'warning' of the book's title, he wrote later, was "originally an appeal, and looked to the future". How far his warnings and those of others have been heeded may be judged by a recently issued Colonial Office publication* which surveys the history of the British territories in the Caribbean and North Atlantic during the past thirteen years. It is the fourth in a series of official reports designed to take a longer view of trends and developments than is possible in the various annual Colonial reports. The previous reports have covered the post-war period in the Far East (Cmd. 7709, 1949), East and Central Africa (Cmd. 7987, 1950), and the British islands in the southern hemisphere (Cmd. 8230, 1951). The present report extends its range backwards to 1939 and even earlier, and it does so wisely, for the situation to-day in these areas is so dependent on the circumstances of the inter-war and war years that it is impossible to understand it without reference to this background.

This point is clearly made in the first chapter of the report, "The Seeds of the Present", which summarizes the position in the period preceding the appointment of the West Indies Royal Commission of 1938–39 and the results of that Commission, and reviews the events of the war-years that followed. The Commission decided that the region was in urgent need of social services which it could not afford from its own resources or from any unassisted development of these resources that was likely in the near future. Considerations such as these in the Colonial Empire generally lay behind the establishment of the Colonial Development and Welfare Fund in 1940: in the West Indies a Development and Welfare Organization was set up with the late Sir Frank Stockdale as its first comptroller and, despite war-time shortages, much re-organization and rehabilitation were carried through. Although, as the report puts it, "the impact of the war was manifold and serious", the end of the War left the West Indies with their basic economy largely intact and with good prospects for the planning of the future.

The chapters that follow and the useful statistical appendixes present a synoptic view of the situation to-day. The survey of political and constitutional development indicates the diversity of political structure and the complexity of local government, as well as the variety of ways in which advance is being made in the different territories from representative to responsible government. It also explains both the difficulties and the prospects of federation, towards which there is a distinct movement in most of the islands and about which a further conference is to be held in London in April.

The economic outlook just before the Second World War was, to quote the Royal Commission, "not at all reassuring", on account of the depression in the main primary-producing occupations of the region and because of the problems resulting from the high natural rate of increase of population. To-day the report states that "the uncertainty of the inter-war years has gone", partly through the development of new markets and of systems of guaranteed prices, and partly because of action taken under the Development and Welfare Acts to strengthen the region's economy, particularly its agriculture. At the same time, some of the economic problems have been intensified: developments in preventive medicine, in particular, by increasing the rate of growth of population, are already increasing the demand for education and for employment. The necessity for "the more intensive use of the land with increased production of food" is as great to-day as when the Royal Commission expressed this need, and it is satisfactory to learn that since 1939 there has emerged a new approach to the question of the most efficient use of the land, for foodstuffs as well as for export crops such as sugar, cocoa and bananas. There has been progress, too, in animal husbandry, forestry, the processing and other industries, and mining (British Guiana is the world's second largest producer of bauxite, which is also now being mined in Jamaica with the financial assistance of the Economic Co-operation Administration of the United

* Colonial Office. "British Dependencies in the Caribbean and North Atlantic, 1939–1952." (Cmd. 8575.) Pp. xi+98. (London: H.M.S.O., 1952.) 3s. 6d. net.

States). Despite these and other developments, unemployment and under-employment remain serious problems, though good progress has been made in the fields of labour supervision and industrial relations.

The general emphasis of the Royal Commission's recommendations was on welfare rather than on development, and it is not surprising to find much more advance in the social services than in economic productivity. The links between the two have been discussed in Britain in recent years, and for the Caribbean were considered by Prof. T. S. Simey (one of the war-time advisers to the Comptroller for Development and Welfare) in his "Welfare and Planning in the West Indies" (1946). Although the report notes that "in recent years it has been increasingly recognised that the maintenance of improved social services calls for intensive and sustained efforts to promote economic development", it very rightly emphasizes the considerable progress made in education, medical services, and social welfare generally.

In the modern world no area can be understood in isolation from its neighbours, least of all these British islands for which, as the report states, "a co-operative policy has been a firm feature of the conduct of affairs". International relations with the United Nations, the United States, Guatemala and Venezuela are discussed, and special attention is given to the significance of the Four-Power Caribbean Commission, which is to concentrate in future less on overall research (much of which has been done) than on those activities that have direct bearing on immediate economic development—agriculture, forestry, fisheries, industrial development and housing, in that order. Reference is also made to the considerable numbers of West Indians working and studying overseas, and to their importance in the two-way process of West Indians knowing the world and being known to the world.

The Colonial Office has produced in this report a very readable, well-balanced and most valuable account of these territories and their peoples. A realistic assessment has been made of the prospects of political, economic and social development, and some at least of the probable limitations on such progress are stressed. The main interest in the period under review has lain not in the discovery of new problems but in the progress made in dealing with them, and in the increasing recognition of the importance of joint action as a means of meeting the economic and other problems of the region. "Increased productivity, as a basis for improved or even maintained standards of living, remains the fundamental need," the report concludes, "and this must be the main objective of Governments and peoples alike in the years to come." Up to a point, this survey has covered the area's problems in a comprehensive and understanding manner: yet nowhere is there any real or sustained analysis of the problems posed by the rapid growth of population in nearly all these dependencies. To-day they have some 3,200,000 people; within a generation it seems there may be five or even six million. If this is so, is not increase of population the major problem of these British territories? Are the individual governments and the Colonial Office really alive to the urgency of this aspect of the future of the Caribbean territories? They probably are, but this report will scarcely give the informed reader that impression.

R. W. STEEL

# HUMIDITY OF THE UPPER TROPOSPHERE AND LOWER STRATOSPHERE

THE troposphere is the lower part of the atmosphere, and the stratosphere the upper part. Temperature in the troposphere on the whole falls with height at the rate of about 3° F. per 1,000 ft.; but in the lower part of the stratosphere it changes little with height. The troposphere and stratosphere are separated by the tropopause, a shallow layer within which the vertical temperature gradient changes rapidly. Over southern England the mean height of the tropopause is about 37,000 ft. in summer and 35,000 ft. in winter, but large variations, sometimes exceeding 10,000 ft., occur on either side of the mean. The tropopause is low over depressions and high over anticyclones.

Within the troposphere there is much mixing of air by convection currents, and this convectional stirring produces the large fall of temperature with height. The temperature distribution in the lower stratosphere is believed to be determined by radiative equilibrium in which water vapour, as the most important constituent of the atmosphere absorbing and emitting long-wave radiation, plays a predominant part. Knowledge of the water vapour content of the upper troposphere and lower stratosphere is therefore important for study of the radiative exchange of heat in the atmosphere. It is also important in connexion with both large-scale and small-scale atmospheric circulations because, provided there is no condensation of water vapour, the ratio of mass of water vapour to mass of air (the humidity mixing ratio) remains constant as the air moves. Another application is to the formation of condensation trails which are important in military aviation.

The temperature at tropopause-level is very low, rarely exceeding − 50° F. (− 45·6° C.) and being often below − 80° F. (− 62·2° C.). This makes humidity measurements difficult, because instruments such as hair hygrometers are extremely sluggish at such low temperatures. The problem of measuring humidity at this level was solved in 1942–43 with the invention by Prof. G. M. B. Dobson and Dr. A. W. Brewer of a frost-point hygrometer operating on the same principle as Regnault's dew-point hygrometer. The instrument can be carried in an aircraft; with it the first observations of humidity in the lower stratosphere have been made, and a detailed analysis of the observations taken with the instrument in the course of 130 flights between 1943 and 1950 over southern England has been published in Geophysical Memoirs No. 88 of the Meteorological Office*.

The most striking feature is the extreme dryness of the lower stratosphere. This was quite unexpected. The mean relative humidity with respect to ice at the tropopause is 41·5 per cent, but at a height of about 6,000 ft. above (more precisely at 50 mb. lower pressure) the mean is only 5 per cent. The frost point in the lower stratosphere is rarely outside the range − 80° F. to − 120° F. (− 62·2° C. to − 84·4° C.). The corresponding saturation vapour pressures are $7 \cdot 8 \times 10^{-3}$ mb. and $2 \cdot 6 \times 10^{-4}$ mb.

---

* Air Ministry: Meteorological Office. Geophysical Memoirs No. 88: Humidity of the Upper Troposphere and Lower Stratosphere over Southern England. (M.O. 530c.) By J. K. Bannon, R. Frith and H. C. Shellard. Pp. 36. (London: H.M.S.O., 1952.) 2s. 6d. net.

At the tropopause there is generally an increase in the magnitude of the rate of fall (lapse-rate) of frost point with height; but this increase usually holds over a shallow layer only, and higher up the lapse-rate returns to the value it had in the upper troposphere. The increase in lapse-rate of frost point at the tropopause is most marked when there is an increase of air temperature with height there. Such an arrangement is characteristic of the tropopause above depressions and is believed to occur because the tropopause moves downwards over a depression. The subsidence of the air of the lower stratosphere necessarily tends to produce an inversion of temperature and a reduction of frost point. When the tropopause is marked in the vertical temperature curve by a reduced lapse-rate and not an inversion, the lapse-rate of frost point shows no tendency to increase there. This is characteristic of anticyclones and occurs because above them the tropopause is lifted up.

The humidity observations are analysed also for variation with season and air mass and the changes which occur on passing through a frontal surface.

The height attainable by the aircraft used for making the observations was not sufficient to enable them to climb into the stratosphere when the tropopause was above about 41,000 ft., and the results have some bias towards low tropopause. It is to be hoped that measurements of humidity to greater heights in the stratosphere will become possible in the future on a routine basis. The Americans Barrett and Herndon have flown an automatic frost-point hygrometer to 100,000 ft. below a very large plastic balloon; but their apparatus (Compendium of Meteorology, American Meteorological Society, p. 1220; 1951) weighed 46 lb. Routine flights with balloon-carried apparatus must await the development of a lighter instrument.

## SOCIAL SECURITY AND UNEMPLOYMENT IN LANCASHIRE

UNDER the title "Social Security and Unemployment in Lancashire", Political and Economic Planning has issued a useful broadsheet (No. 349; December 1, 1952) analysing the effects of unemployment on the working of the more comprehensive social security measures now in existence. The information was sought particularly from the cotton towns, and, although the survey is too limited to throw light on the adequacy of benefit and assistance payments, it confirmed the conclusion reached in an earlier broadsheet that actual patterns of expenditure by poorer families differ widely from that accepted as the basis of social security payments. Families appear to draw extensively on savings, and, failing these, economize on food and fuel to maintain certain types of expenditure, including even entertainment, as long as possible. The survey has shown that relatively few of the unemployed in Lancashire have applied for national assistance. This is partly due to ignorance or misunderstanding about the regulations, especially those concerning house ownership and the amount of savings which are to be disregarded in assessing need. Something less than half of those who would qualify for assistance seem ready to ask for it.

While on the whole the machinery of the scheme appears to have been put into motion quickly and smoothly, and regulations too have been administered in the spirit of the new Acts, the survey has shown that many people do not qualify for benefit, or qualify only for less than the standard amount. Most of the former are married women, and P E P makes the point that, when married women have to stay at home from time to time for such reasons as looking after their children or an invalid dependant, there is a strong case for relaxing the contribution conditions so as to enable more married women to draw benefit, either by crediting them with insurance contributions or by permitting them to continue contributions as if they were still in employment. Workers with secondary, part-time occupations are also in an anomalous position, and P E P suggests that the Ministry of National Insurance should review the regulations concerning subsidiary earnings in the light of recent experiences in Lancashire.

The evidence collected in Lancashire must obviously be interpreted with great caution for other areas; and P E P directs attention to the difficulty in making precise judgments about the working of the social services in Lancashire, because of the gaps in information which exist and the different methods by which the various official statistics are collected and presented. If for good reasons unemployment and national insurance statistics cannot be made comparable, it suggests that sample inquiries in circumstances such as those in Lancashire during recent months would provide evidence of material value to administrators and others concerned with the social services as well as to research workers.

## BREEDING BEHAVIOUR OF THE SWIFT

THE breeding biology of the swift (*Apus apus*) has been studied by David and Elizabeth Lack (*British Birds*, **44**, No. 6; June 1952). The first observations were made in 1946 on birds nesting in holes in thatched roofs in villages near Oxford; attempts were made later to induce the birds to breed in nest boxes. For many years swifts had nested in the ventilators in the tower in the Museum of Oxford and, in 1948, platforms were erected inside the tower and ventilators were replaced by nest boxes to which glass backs were fitted. The observers could now sit in semi-darkness a few inches from the birds, watching against the light from their entrance holes without causing them any disturbance. The paper describes the behaviour recorded.

Most adult swifts show little fear in their boxes, presumably owing to lack of natural enemies at the nest. There is, however, great individual variation. Some were extremely tame from the start and were not at all disturbed when, in weighing experiments, the eggs or young under them were removed and later replaced. Others at first left the box if a hand were inserted, but became tame through repeated handling. Some fiercely attacked an inserted hand with their claws, and displayed if noises were heard outside the box or objects seen near the glass.

The observations showed that each year about twenty pairs laid eggs, and several non-breeding pairs, possibly in their first year, occupied other boxes. The adults arrived in spring and departed in summer over about three weeks, the two members of each pair usually arriving and departing separately. Each pair normally rested in their boxes throughout the summer.

Adults were seen to visit the boxes at any hour of the day but especially around 7.30 a.m. and 6 p.m., sometimes sheltering in the boxes in rain. In fine weather single individuals or small parties might fly up to and brush against the boxes and were treated as strangers by the pairs. When another swift entered the box it was often treated with incipient threat display. If it were the bird's own mate, the display quickly gave place to mutual preening; if it were a stranger, a fight sometimes followed. Little preliminary display took place before coitus, which occurred in the boxes.

Nest building was observed to start on the day that the pair was formed and continued until the end of incubation, the material being stuck down with saliva. Non-breeders were observed to build throughout the summer. If a clutch of eggs were lost for any reason a repeat clutch sometimes followed. Part or the whole of the clutch was sometimes ejected, the ejected eggs being sometimes fertile. The reason for ejection is still obscure.

Parent birds took an equal share in incubation, the time of each sitting varying from 2 to 345 minutes; the eggs were sometimes left uncovered during the day for periods of up to 6¼ hours. Although considerable investigation was undertaken, the influence of weather on the incubation rhythm was found to be obscure. The parents brood the young by day almost continuously in the first week and for about half the time in the second week, but very little thereafter.

Feeding habits showed that the parent brings a mass of insects stuck together with saliva, this being normally passed in a single food ball to one nestling; with very small nestlings the food ball was divided. The parent swifts readily adopted a strange nestling added to or in place of their own. The parents moved some of the fæces but many others were left in the boxes, the older nestlings sometimes defæcating from the hole.

In a description of the fledging habits, Mr. and Mrs. Lack record that at Oxford most young swifts left the nests between the third week of July and the third week of August, the latest being on September 7. The young left equally in good and bad weather and departed in a steady stream, most of them leaving over a period of three to four weeks.

The young swift left the nest fully able to take care of itself and was assumed to migrate on the day that it left the nest. Nearly all the departures were in the morning, and no fledgling returned to its box. It was also reported that, in 1951 at least, most of the parent swifts stayed for several days after the departure of their young.

# MAGNETIC MEASUREMENTS IN DEEP-SEA INVESTIGATIONS

## Construction of Non-magnetic Containers

FOR its biological investigations the ship *Galathea* of the Danish Deep-Sea Expedition round the world during 1950–52 was equipped with a longer wire and a more powerful winch than previous deep-sea expeditions. Due to this and the fact that the construction of magnetometers of high precision has been specially developed in Denmark through the work of the late D. la Cour, it was thought natural to take up on the *Galathea* expedition also the problem of measuring the variation in the oceans with depth below sea-level of the magnetic field of the earth. The problem of the origin of terrestrial magnetism being still an open question, such measurements may elucidate this problem, which has become of special interest through the recent investigations of Blackett, Bullard and Elsasser. In this and the following note is described the work with this object.

To contain the magnetometers and protect them against the pressure of the water, which at the greatest measured ocean depths was about 1,000 atm., special water-tight containers had to be constructed of a non-magnetic and sufficiently strong material. None of the existing alloys known to us fulfilled both requirements except the aluminium alloy 'Hiduminium *RR*77'. Unfortunately, this alloy cannot be cast but only forged, a procedure which could not be used due to the limited economic resources and time at our disposal. However, Messrs. Paul Bergsøe and Son produced a new alloy satisfying all our requirements. This alloy is a completely iron-free β-manganese bronze with a high content of aluminium. Its characteristics are: magnetic permeability, less than 1·01; elastic limit, 28 kgm. per mm.$^2$; 0·01 per cent limit, 29 kgm. per mm.$^2$; 0·2 per cent limit, 38 kgm. per mm.$^2$; tensile strength, 70–80 kgm. per mm.$^2$ at an elongation of 10–20 per cent; Young's modulus, $E$ = 6,100 kgm. per mm.$^2$; density, 8·1. (A detailed account of this alloy is to be published shortly in Great Britain.) Messrs. Burmeister and Wain constructed two containers of this material, which for mechanical reasons were made in the form of spheres. The first container, shown in Fig. 1, is a single sphere, internal diameter 50 cm., wall thickness 10 cm., weight 1,100 kgm. The second container, shown in Fig. 2, consists of two single spheres like the former, connected by a tube 100 cm. long. Its total height is 270 cm. and total weight 1,700 kgm.

From experience with diesel engines, the containers were made water-tight without any packings, simply by direct contact between the polished surfaces of the single half-spheres, which were made as plane as technically possible.

The double sphere has been lowered four times to a maximum water depth of 6,900 m. It was found to be completely water-tight on all four occasions. The single sphere has been lowered twenty-nine times to various depths down to a maximum of 10,000 m. in the Philippine Trench. At the beginning some water leaked into the single sphere. This was found to be due partly to casting stresses, which gradually disappeared, and partly to the surfaces of its two halves being not perfectly plane, thus needing extra grinding and checking by means of a normal plane. In this way we reduced the leakage to the insignificant amount of 40 cm.$^3$ at a depth of 5,000 m. Lack of time did not allow us to make further experiments to remove this residual water.

Finally, the elastic properties of the containers were tested. For this purpose the horizontal internal diameter of 500 mm. was measured before and after the descent of the single sphere to 10,000 m. in the Philippine Trench. A reduction of diameter of at most 0·04 mm. was found. The corresponding figure for the double sphere at a depth of 6,900 m. was 0·01 mm. Also the elastic reduction of the spheres while lowered was measured. At a depth of 6,900 m. we found that for the double sphere the vertical internal diameter of 500 mm. had been reduced by

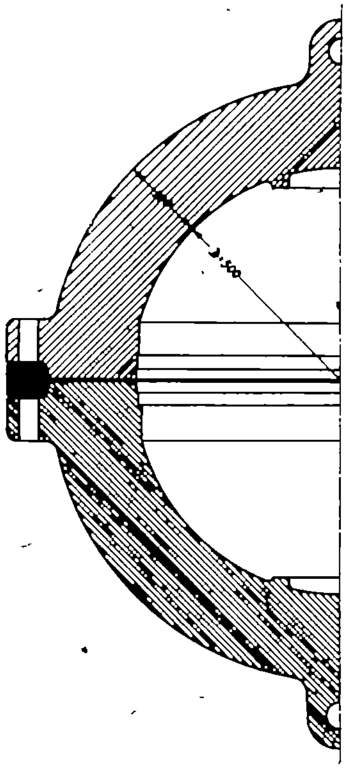

Fig. 1

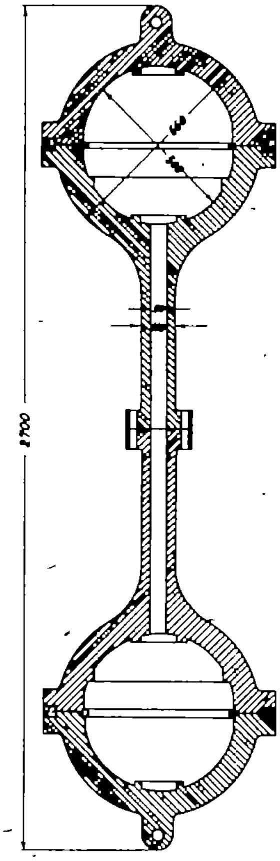

Fig. 2

at most 1·2 mm., that is, by an amount not exceeding 0·24 per cent.

Thus our results show that it is possible to construct containers allowing ordinary magnetic and other physical instruments to be lowered to even the greatest ocean depths. Apart from magnetic work, these spheres may also be used for gravimetric, seismic, cosmic ray and other work. We shall be very pleased to put our spheres at the disposal of others for such investigations.

## Magnetic Investigations on the *Galathea* Expedition

Three self-recording, relative magnetometers have been constructed: (*a*) and (*b*) measuring the horizontal component $H$, and (*c*) measuring the vertical component $Z$. The principle of (*a*) and (*c*) is that the deflexion of a magnetic needle of the la Cour monad type from a vertical and a horizontal position, respectively, is measured optically on a moving photographic film. The principle of (*b*) is that the earth's field induces an alternating current in a coil rotating about a vertical axis. This current is recorded on a magnetic recorder after having been amplified by an electronic amplifier, the amplification of which is inversely proportional to the frequency with which the coil rotates. Instruments (*a*) and (*c*) are housed successively in the single sphere, (*b*) in a double sphere, described in the preceding communication. The lower sphere of the double sphere contains the coil driven by an axle through the tube, with a motor in the upper sphere, which contains also the batteries for the motor, the amplifier and its batteries, and the recorder. To obtain sufficiently high measuring accuracy in all three instruments, most of the field to be measured is compensated by suitable magnets, so that only a small fraction is actually measured. Furthermore, in (*a*) and (*b*) these compensating magnets have the form of compass needles to give the direction of the magnetic meridian.

Within a total time of about 270 hr. which could be spent on magnetic work at sea during the expedition, our instruments were lowered twenty times to various depths of water down to 5,000 m. The first part of our programme was to make trial experiments with the instruments and adjust them to the working conditions at sea, to work out the method of observation such as manœuvring the ship, checking the tables of Vestine *et al.*[1] which form the basis for the adjustment of the instruments, investigating the perturbing effect of the ocean bottom, and so on. The second part of the programme was to use the results of the first part to take measurements at a depth of water of 5,000–6,000 m. in the central part of the Pacific Ocean, which offers great areas with flat bottom. However, due to lack of funds to meet the rising prices, the working time of the expedition had to be cut down. Thus lack of time prevented us from carrying out the second part of our programme.

The main problem in reaching the desired measuring accuracy, namely, about 10 γ, was found to be the fact that due to the weight of the spheres the wire unwound itself, thus rotating the spheres about the vertical with speeds too fast for the instruments. (To investigate both the rotation and oscillations of the spheres a special instrument was constructed recording the motion of the spheres.) This problem was solved by means of a special ball-bearing swivel inserted between the sphere and the wire, a 3-m. long aluminium rudder on the sphere, and finally by manœuvring the ship in such a way that at each depth at which magnetic measurements were taken the sphere moved horizontally at about 1 knot, which speed was found to be sufficient for the rudder to keep the spheres in a definite azimuth.

The following results were obtained. A method has been worked out whereby in any event an average value for $H$ with an accuracy of about 5 γ can be measured within an hour down to at least 3,000–4,000 m. Furthermore, at a given depth at which magnetic measurements were taken the observed variation of the field with the position of the sphere showed that a rugged ocean bottom gave considerable perturbations as long as the instruments were not at least 2,000–3,000 m. above the bottom. Finally, we found that at most stations the tables of Vestine *et al.*[1] agreed surprisingly well with the field we observed. However, at a few of our stations in the Pacific we observed anomalies where the field deviated by about 500 γ in $H$ and about 1,000 γ in $Z$ from the values given in the tables.

Although on the stations given by the plan of the expedition it was not possible to eliminate with certainty the perturbing effect of the bottom, all our measurements indicate that both $H$ and $Z$ increase numerically with increasing depths below sea-level. These findings are in agreement with what has recently been found in mines by Runcorn *et al.*[2]. Lack of time prevented us from obtaining on this expedition a physically reliable measurement of the vertical gradient of the field independent of the perturbing effects of the bottom, but we hope to be able to utilize our experiences and results on future deep-sea expeditions, and we ask anybody planning such expeditions to get into touch with us to consider the possible continuation of this work.

A detailed account of the present work will be published in the *Journal of Geophysical Research*.

# A NEW METHOD FOR THE PAPER CHROMATOGRAPHY OF OLIGOSACCHARIDES

By R. J. BAYLY and DR. E. J. BOURNE
Chemistry Department, University, Birmingham 15

ALTHOUGH the application of paper chromatography to the separation and identification of bioses and higher saccharides was reported in 1948 by Partridge[1], and has since been used with advantage in numerous studies, the effectiveness of the method is still limited considerably by the low $R_F$ values of these substances. In theory, the absolute distances separating components can be suitably increased by prolonging the irrigation time to several days; but, unless excessive care is taken, such a procedure often results in irregularities of the solvent front, and in any event is frequently too lengthy to be of use. Alternatively, the rate of movement of the oligosaccharides down the paper can be increased, as described by Hough, Jones and Wadman[2], and by Jeanes, Wise and Dimler[3]. The former workers ran the chromatograms at 37°, a procedure which is not altogether suitable for general use. Jeanes *et al.* increased the water content of the solvent and also introduced the multi-development technique; for example, with a solvent containing equal parts of fusel oil, pyridine and water, two to four developments, each of 22 hr., gave discrete spots of amylosaccharides ranging from maltose to the decaose. We now report a new method, based on a different principle, by which considerable increases in $R_F$ values (about eight-fold for disaccharides) may be effected; it involves the conversion of the oligosaccharides, on the chromatogram, into the corresponding N-benzyl glycosylamines, thus reducing their preference for the cellulose–water phase. Conditions suitable for the resolution of dextrins containing up to about ten sugar units have been determined; but there is no reason why, when the necessity arises, this range should not be extended by further modifications of the type described by Jones[2], Jeanes[3] and their co-workers.

After studies of the various factors involved, the following method was selected as being most suitable for general purposes: a spot of the sugar solution (2 μl.) is allowed to dry on the paper (Whatman No. 1), a spot (3 μl.) of a 10 per cent solution (w/v) of benzylamine in methanol is superimposed, and the paper is heated at 85° for 5 min., before being irrigated in the usual way with the upper phase of an *n*-butanol–ethanol–water–ammonia (40 : 10 : 49 : 1) mixture. After being dried, the paper is sprayed with a 0·25 per cent solution of ninhydrin in ethanol. The spots begin to appear within an hour, are fully developed after about 12 hr., and begin to fade after three days. The excess of benzylamine forms a band at the solvent front.

It is important that the sugar and benzylamine spots should be applied in the order given above; for best results only one spot of the sugar solution should be applied, otherwise succeeding spots tend to concentrate the sugar in a ring and the benzylamine is then less effective. Moderate amounts of impurities, such as mineral matter, organic acids, etc., do not interfere with the condensation. In view of the excessive amounts of benzylamine used, the initial spots of different test mixtures should not be closer than 3 cm. Although the N-benzyl glycosylamines stain with aniline hydrogen phthalate almost as well as the corresponding free sugars, the ninhydrin spray is more sensitive, and, moreover, does not detect the free sugar (c. 20 per cent) which remains after the reaction with benzylamine. About 5 μgm. of maltose or panose can be detected comfortably in an 18-hr. run; there does not appear to be any tendency for a major constituent in a sugar mixture to mask a minor one, provided that their $R_F$ values differ sufficiently to permit the formation of discrete spots. It is desirable that the initial sugar solution should be free from impurities which, after development with an ammoniacal solvent, will stain with ninhydrin (for example, amino-acids, high concentrations of carboxylic acids); but if such impurities cannot be avoided, then their behaviour on a chromatogram must be known. A distinction between amino-acids and fairly strong spots of N-benzyl glycosylamines can be obtained by heating the sprayed paper for 2–3 min. at 85° after drying; under these conditions the glycosylamine derivatives, in contrast to the amino-acids, stain brown before turning to purple. Such heating causes no marked reduction in the time taken for N-benzyl glycosylamine spots to reach their maximum intensity. As evidence that the sugars do, in fact, move as N-benzyl glycosylamines, the spot obtained in the case of glucose has been shown to correspond to that of authentic N-benzyl glucosylamine[4] run in the same solvent ($R_F$ c. 0·7).

Typical mixtures which can be resolved by the general method in 18 hr. are: (*a*) maltose and *iso*maltose; (*b*) *iso*maltotriose and panose; (*c*) maltopentaose and maltohexaose (see also Fig. 1). The method is satisfactory for galactose, mannose, rhamnose and xylose (and presumably for oligosaccharides derived therefrom), but not for fructose. The N-benzyl glycosylamines of arabinose and ribose appear to be rather unstable under the conditions of the general method, but suitable modifications doubtless could be devised to meet these cases, if required.

For mixtures of disaccharides which give benzylamine derivatives with almost identical $R_F$ values, it is usually better to employ an irrigating solvent containing less water than in the general method; for example, a distinction between *iso*maltose and gentiobiose can be observed readily in 28 hr. using the organic phase of a butanol–ethanol–water–ammonia (45 : 5 : 49 : 1) mixture (see Fig. 2).

With mixtures containing the higher oligosaccharides, improved results are obtained if the general method is modified in two ways: (*a*) by using a solvent of higher water content, namely, a mixture of butanol, ethanol, water and ammonia (40 : 12 : 20 : 1), and (*b*) by using a more efficient method of equilibration (see below). Under these conditions, the benzylamine derivatives of the higher homologues of maltose and laminaribiose have, respectively, the following approximate $R_F$ values: tetraose, 0·36, 0·45; hexaose, 0·19, 0·32; octaose, 0·07, 0·21. Since laminarioctaose moves 8 cm. from the starting line in a 19-hr. run, it is clear that the method is capable of dealing with even higher saccharides, particularly if the running time is extended, or the water content of the solvent is increased still further. Within the range of saccharides examined, there seems to be little or no decrease in staining power, per reducing group, with increasing chain-length.

Thorough equilibration of the tank before the commencement of the run has a markedly beneficial effect on the $R_F$ values of the slower-moving oligosaccharides. The usual method of equilibration, involving the use of trays of the solvent mixture in the bottom of the tank, takes at least 24 hr. and, during this time, glycosylamines are sometimes produced by interaction between ammonia vapour from the solvent and the N-benzyl glycosylamine spots. Since ammonia is essential in order to prevent hydrolysis of the N-benzyl glycosylamines, the following rapid method of equilibration was used. A blank sheet of filter paper was dipped into the irrigating solvent and suspended from a second trough in the tank. The solvent was introduced immediately into this trough, and the tank was sealed for 45 min., before the solvent was introduced through an orifice into the trough supporting the actual chromatogram. The degree of equilibration thus attained was better than that effected in 24 hr. in the usual way. Although this simple technique was designed primarily for use with the higher oligosaccharides, we find it beneficial also in the general method.

Fig. 1. Chromatogram run for 18 hr. according to the general method. Besides glucose, spots are apparent corresponding to the oligosaccharides containing up to six glucose units in the 1 : 4-α series, and up to five in the 1 : 6-α and 1 : 3-β series

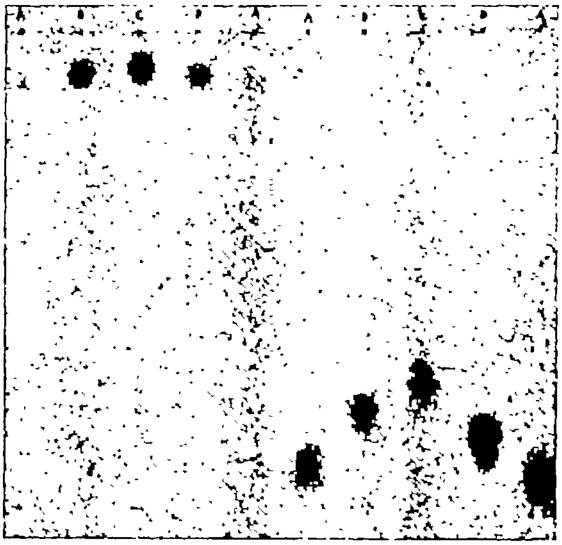

Fig. 2. *A*, maltose; *B*, *iso*maltose; *C*, gentiobiose; *D*, lactose. *Right:* Sugars treated with benzylamine and chromatogram sprayed with ninhydrin. *Left:* Identical sugar solutions run in the same solvent in the normal way and chromatogram sprayed with aniline hydrogen phthalate

Following earlier theoretical considerations[5], Bate-Smith and Westall[6] deduced that $\Delta \log \left(\frac{1}{R_F} - 1\right)$ should be constant within a homologous series; they obtained good experimental confirmation with various phenolic compounds. Jeanes *et al.*[7] demonstrated later that the relationship, and also its approximation for low values of $R_F$, namely, $\Delta \log 1/R_F$, were true for a series of amylosaccharides. The benzylamine method enables these relationships to be tested over a wide range of $R_F$ values. Preliminary studies with partially hydrolysed amylose and laminarin have shown good agreement, glucose excepted, with the relationship of Bate-Smith and Westall[6]; but, rather unexpectedly, with partially hydrolysed dextran, Jeanes's approximation holds better. A fuller examination of these and other homologous series of oligosaccharides, covering all types of glucosidic linkages, would enable a possible structure(s) for any oligosaccharide containing mixed glucosidic linkages to be assigned more accurately than in the past from the position of its spot relative to suitable markers. One advantage which would be gained thereby is that, if a trisaccharide of this type were detected in the hydrolysis products of a polysaccharide, then the two different linkages of the triose would be proved to be adjacent in the polysaccharide itself.

In partial hydrolysates of the dextran synthesized by *Betacoccus arabinosaceous* (Birmingham strain) we have observed, *inter alia*, spots corresponding to a 1 : 3-biose and (more faintly) to a triose ; the position of the latter spot indicated that the triose contained a 1 : 6- and a 1 : 3-link. These observations suggested that the linkages at the branch points of this particular dextran molecule were of the 1 : 3-type, and not of the 1 : 4-type, as has been believed hitherto[7]. A full chemical analysis has confirmed that this is so[8].

Again, a partial hydrolysate of the polyglucosan of *Aspergillus niger* (strain 152), which was known already to contain 1 : 4- and 1 : 3-links in almost equal amounts[9], showed only one triose spot, the position of which indicated that it contained one of each of these linkages. Thus, it was highly probable that, in the polyglucosan, the 1 : 4- and 1 : 3-glucosidic bonds were arranged alternately; confirmatory evidence of this has now been obtained by other methods[10].

The above observations are reported in the belief that they represent a real advance in the chromatography of oligosaccharides ; and, to the extent that paper chromatography is a useful preliminary to the isolation of crystalline reference compounds, that they will aid the determination of polysaccharide structures.

We are indebted to Prof. M. Stacey for his interest and advice, and to Dr. E. T. Dewar who kindly supplied the laminarin employed. [Sept. 29.

# PATTERN DISCRIMINATION AND THE VISUAL CORTEX

By D. A. SHOLL

Department of Anatomy, University College, London

AND

A. M. UTTLEY

Telecommunications Research Establishment, Great Malvern, Worcs.

DURING recent years attempts have been made to explain the organization of the cerebral cortex in terms of electronic computing machines. Comparisons have been made with two-way switches, regenerative storage systems and cathode ray tube scanning-systems ; yet none of these analogies has met with general acceptance, nor have they led to testable hypotheses.

We have made an attempt to examine some of the problems associated with pattern discrimination and the organization of the visual cortex by means of two approaches, each of which is fundamentally statistical. On one hand, some of the elements of the visual cortex have been described in a statistical manner (D. A. S.) while, on the other hand, the organization of a machine operating on a probability basis has been explored (A. M. U.). It is suggested that a valuable analogy exists between the two methods of study. Some relations between them are beginning to emerge, and already there has been a surprising measure of agreement between hypotheses suggested by the theory of the machine and the experimental observations of cortical structure.

There is reason to believe that many of the complexities of the cerebral cortex are due to an organization that is fundamentally of a statistical nature and the parameters of which can only be described in terms of probabilities. One of the obstacles to the formulation of adequate hypotheses for many branches of biology has been the language and mathematics which have been used in attempts to frame these hypotheses ; consequently, some of the concepts that we introduce will be strange to biologists. Nevertheless, we feel that the effort to master this approach will be amply repaid.

First of all, the finer branches of the axons running from the thalamus to the primary sensory areas of the cerebral cortex end in an apparently random manner among the surrounding cells and their dendrites. Quantitative study of the lengths of the dendritic processes and their branches shows that there is no simple law relating these lengths to the position of the cell or the size of the perikaryon.

With this background, one of us (A. M. U.), working in the field of computer design, has proposed definitions of the word 'pattern' in terms of set theory, and of 'measure of pattern difference'. These definitions have led to the design of an efficient machine with random connexions between its units and the inputs, and with the ability to measure differences between a representation and a constantly changing statistical description of past representations.

By a 'representation' is meant a set of physical quantities internal to a machine, which are determined by an external physical configuration and may be called attributes of it ; each attribute will have a measure, which may be continuous or discrete. By a 'pattern' is meant a subset of such measures. A machine for comparing a present representation with a past ensemble of representations, member by member, requires a storage capacity that must grow with the ensemble, and each comparison leads only to a binary statement of identity or difference. If, on the other hand, a statistical method of describing the ensemble of representations is used, whereby the ensemble is specified by the relative frequencies with which the different sets of attributes have occurred in the past (or the probabilities that the members of the 'given' ensemble possess certain sets of attributes), and if the comparison is made only with this system, then a constant storage capacity is all that is required. For example, if there are $n$ input quantities (attributes) and each has $s$ possible discrete measures, the number of different possible representations can be shown to be $(1 + s)^n$ ; this is the fixed number of descriptive probabilities that must be stored, regardless of the number and type of past representations.

The simplest possible machine of this nature must employ the simplest possible measure for which $s$ is unity. In this case, either a proposition of the form 'the configuration $A$ possesses the property $j$' is made, or no proposition is made at all. This measure will be called unitary, in contrast with binary measure in which an additional proposition of the form 'the configuration $A$ does not possess the property $j$' is made. The input, therefore, must possess two states; if it is active, a proposition is made, and if it is inactive, no proposition is made.

An example of the kind of mechanism that could provide an input of this unitary nature would be a threshold-operated detector which could be in one of only two states. The detector would be in an active state if, say, a chemical concentration or a packet of radiant energy exceeded a certain value; otherwise the detector would be inactive. There must be no varying degree of activity in any one input channel to the machine. In consequence, for detectors of a different nature, it would be necessary to interpose a coding system between them and a machine of the type which has been described.

Using this unitary measure, a complete non-redundant statistical description of an ensemble of representations consists of the joint probabilities of occurrence of all possible sets of attributes. It is therefore necessary to have units capable of counting and storing these probabilities; and the units must be connected to the inputs in all possible ways. This can be achieved precisely by random connexions between the input points and the units of the machine; it can be shown that if the chance of any unit being connected to any particular input is ½, each unit will be replicated about the same number of times. Other laws describing the probabilities of connexions will lead to other population distributions.

In order to define a measure of pattern difference between a present representation and a past ensemble in respect of a set of attributes, the following axiom is laid down: if the set can be separated into two subsets with *a priori* independence, the pattern difference in respect of the total set is the sum of the pattern differences in respect of the two subsets. From this it can be shown that the only possible measure of pattern difference is the negative logarithm of the *a priori* probability of the set; if the set does not occur in the present representation, there is no measure of pattern difference. Probabilities must therefore be computed in the units on a negative logarithmic scale.

For a past ensemble occurring as a sequence in time, each unit must have two properties: it must possess some quantity which grows approximately logarithmically with time, and the act of counting must consist in the destruction of some of this quantity. Different mathematical laws of growth and destruction lead precisely to different weighting functions of past events. The act of counting must occur only if all the connected inputs are in the active state caused by occurrence of the corresponding attributes.

The machine can be extended to measure a difference in respect of a pattern, even if some of its attributes have not occurred; it can be shown that the measure must be the negative logarithm of the conditional probability of the set of attributes.

Conditional probabilities can be computed in the following manner. Consider attributes $j$, $k$ and $l$; there will be units storing $-\log p(jkl)$ and $-\log p(jk)$, the negative logarithms of the probabilities, in the past, of the sets $(jkl)$ and $(jk)$. If $(jk)$ occurs, then the conditional probability of the set $(jkl)$ is $p(jkl)/p(jk)$; so that on a negative logarithmic scale the $(jkl)$ unit should contain $-\log p(jkl) - (-\log p(jk))$. This can be achieved if the momentary decrease in the $(jk)$ unit, from $-\log p(jk)$ to zero, is communicated to the $(jkl)$ unit. This effect has been called supercontrol; it leads to precise laws defining the connective function between units; these laws are different from those required between inputs and units for counting purposes. An electromechanical model of the basic unit has been built embodying the principles described and which possesses all the necessary properties of counting, storing and interconnexion.

Returning to the problem of random connexions, the simple statement that the probability of connexion is ½ cannot lead to a knowledge of the position of units in relation to a set of inputs; this will be determined by the manner in which the probability of connexion depends on the position of the input relative to the unit. It can be said that there is a connective probability field surrounding a unit; from the form of this field it is possible to calculate the distribution of units which are directly connected to inputs for the purpose of computing unconditional probabilities. Supercontrol employing interconnexions between units leads to the concept of an indirect connective probability field. For the two forms of control to be effective, the direct and indirect fields must be of approximately the same form; it can be shown that this is met if they fall off exponentially with distance from the unit.

It is possible to define the probability of connexion between an incoming axon and cortical dendrites according to our limited knowledge of the physiology of the connective process and the morphology of the cell. It has been shown experimentally (D. A. S.) that this direct connective probability field does, in fact, fall off exponentially with distance from the perikaryon. This is equally true of the basal dendrites of the pyramidal cells.

To calculate the actual numbers of connected units a second factor is required, the packing density of the perikarya; this has also been determined. It has therefore been possible to predict the population distribution of cells connected to different numbers of afferent fibres.

Finally, we wish to stress the fundamental importance of the decisions: (*a*) to base the theory on the statistical description of an ensemble; (*b*) to adopt a continuous measure of pattern difference; and (*c*) to employ a unitary measure of attributes. The binary measure of pattern difference leads to binary machines employing the gating principle; such a pattern machine can handle two-valued logic, but it can compare only single items, not ensembles. The result of the comparison is of the form '$A$ differs from $B$' or '$A$ does not differ from $B$'. The continuous measure leads to statistical machines employing the analogue principle; such pattern machines can compare two ensembles, or a single item with an ensemble. The result of the comparison is continuous and has the form 'Item $A$ differs from ensemble $C$ by more than does item $B$'.

A full account of the mathematical concepts involved and a detailed description of the application of the theory to specific problems will appear elsewhere.

We wish to thank Prof. J. Z. Young for his encouragement and valuable criticism of this work. Acknowledgment is made by one of us (A. M. U.) to the Chief Scientist of the Ministry of Supply for permission to publish this paper. [Nov. 20.

## Investigation of the Cœlacanth

It was my privilege to carry out detailed investigations on the first Cœlacanth, and to have discovered what appears to be the area where those fishes still live.

The recent Comoran Cœlacanth, while mutilated more than was at first realized, nevertheless retains most of the soft parts, including the abdominal viscera. This extends enormously the scope of the investigational work that may be carried out on the specimen. There will be still more that can be done only on parts, exudates, and secretions from an untreated fresh specimen, which it is hoped to seek before very long.

It is in keeping with the importance and scope of the investigations on all parts of this fish that they should be assigned to leading experts in the field in which they fall. I have advised the South African Council for Scientific and Industrial Research, and have requested the Council's approval of and co-operation in this matter.

Application to be included in this scheme should be sent either to the South African Council for Scientific and Industrial Research, P.O. Box 395, Pretoria, or to me personally at Rhodes University, Grahamstown. While every possible facility will be granted to selected visiting specialists, it should be noted that there is no possibility of financial aid from this end.

The ownership of the next specimen or specimens is of less importance than their proper preservation for scientific purposes. As certain organs and body fluids require special treatment and preservation, it is intended to compile a set of special instructions to be issued to those in areas where it is possible that a fresh Cœlacanth may be obtained. It will be appreciated if those interested will kindly furnish detailed special instructions composed in language as simple as possible, giving full directions and not only the names, but also the actual composition of any materials to be employed.

Since there is a hope that more Cœlacanths may be found at the Comoro Islands, it is desirable that all such materials should be available there.

## Plastic Properties of Coking Coals

The processes which take place when a coking coal is turned into coke by heating in the absence of air are very complex and only partly understood, though they have been studied for many years[1,2]. We have made a renewed approach to the problem, and have evolved for guidance an elementary theory applicable in the temperature-range within which coking coals show plastic properties. Supporting experimental evidence is described below.

It is widely accepted[1] that a coking coal at temperatures of the order of 300° C. and higher shows plastic properties, the word 'plastic' being used here in a general sense; and there is evidence that it behaves as a liquid having a normal viscosity–temperature relationship[3]. At temperatures approaching 400° C., this liquid is subject to thermal decomposition and changes into a gas and an infusible solid. We assume this change to take place according to the laws governing first-order chemical reactions, so that if at time $T = 0$ there exists a mass $m_0$ of coal in the liquid state, at a later time $T = \tau$ there will remain a mass:

$$m_\tau = m_0 \exp - k\tau,$$

where $k$ is the velocity constant of the decomposition reaction at the temperature of the decomposition; and at any later time $T = \tau + t$, there will be:

$$m_{\tau+t} = m_0 \exp - k(\tau+t) = m_\tau \exp - kt. \qquad (1)$$

The time $T = 0$ can never be experimentally realized, as some decomposition must take place in the period of heating to the required temperature, which for reasons of fundamental and experimental limitation cannot be made infinitely short. The time $T = \tau$ is taken to be the time when the predetermined temperature has been reached.

As the solid product of decomposition accumulates, the viscosity of the liquid/solid mixture will rise. We assume a relationship of the form:

$$\bar{\eta} = \eta(1 + \lambda c),$$

where $\lambda$ is a constant later shown to be equal to, or not far from, unity, $\eta$ is the viscosity of the mixture before the concentration of solid matter is increased by $c$, after which it becomes $\bar{\eta}$. (A fixed value of $\lambda$ cannot be assumed, *a priori*, to apply over a long period of time, but it can be shown that it approaches constancy over periods which are not infinitesimal. Idealized extreme cases of solid suspensions and analogous systems have been studied by G. I. Taylor[4] and A. Einstein[5].) It follows that

$$\eta_{\tau+t} = \eta_\tau \left(1 + \lambda \frac{m_\tau - m_{\tau+t}}{m_{\tau+t}}\right); \qquad (2)$$

and substituting from equation (1), we have:

$$\eta_{\tau+t} = \eta_\tau (1 + \lambda \exp kt - \lambda),$$

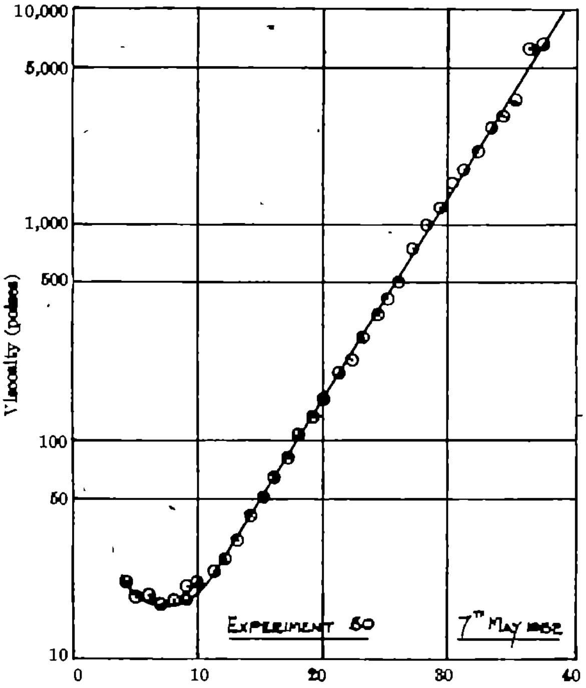
so that:

$$\frac{d}{dt}(\log \eta_{\tau+t}) = \frac{\lambda k \exp kt}{1 + \lambda \exp kt - \lambda} = \frac{\lambda k}{(1-\lambda)\exp(-kt) + \lambda}. \qquad (3)$$

This equation makes the following statements concerning the slope of the graph of $\log \eta$ against $t$: (i) for $t \to 0$, the slope tends to $\lambda k$; (ii) for $t \to \infty$, the slope tends to $k$. Thus, as $t$ increases, the slope changes from $\lambda k$ to $k$.

The predictions of the theory were checked by measuring the viscosity of four different coals at various temperatures using an apparatus developed by Gieseler[6] and other workers[7]. A stirrer is embedded in compressed powdered coal in a crucible. A torque is applied to the stirrer which makes it rotate when the coal softens on heating. The viscosity of the coal is inversely proportional to the rate of revolution of the stirrer. In the past, the apparatus has been used for observing the viscosity changes with rising temperature, but there is no difficulty in adapting it to work at constant temperature.

The graph shows the result of a typical experiment. A linear relationship between $\log \eta$ and $t$ is clearly shown. The precision of the experiment is such that a slight curvature would not be detected. Exact linearity would imply $\lambda = 1$ (see equation 3), so that the slopes give the reaction velocity directly. The graphs obtained permit the statement that $\lambda$ is a



Results of a typical experiment on 'Manvers coal' at 414 ± ½° C.; the slope is 0·094 min.$^{-1}$

constant in the range $0{\cdot}8 < \lambda < 1{\cdot}2$. The value of $\lambda$ does not affect the calculation below.

Experiments have been carried out at a number of temperatures, for each coal, so that the values of $\lambda k$ can be used to find the activation energy of the carbonization process, using Arrhenius's equation:

$$\log k = \frac{-E}{RT} + \text{constant},$$

where $E$ is the activation energy, $R$ the gas constant, and $T$ the absolute temperature. Graphs of log $k$ against $1/T$ gave straight lines for each of the coals examined.

The table gives details of the four coals used, together with the activation energies found. It is interesting to note that although these coals differ widely in their coking properties, assessed by conventional criteria, all the activation energies are near 50 kcal./mole, which has been quoted as the energy required to break the carbon–carbon bond in the thermal decomposition of mineral oils[9].

## Selenium Hexafluoride: Dielectric Strength and some Chemical Properties

THE physical and chemical properties of selenium hexafluoride have received little investigation[1,2]. We have prepared selenium hexafluoride by reaction of the elements at 300° C. in a copper tube, and found that, provided steps are taken to return selenium tetrafluoride (boiling point, 106° C.) to the reaction zone, a yield of more than 90 per cent selenium hexafluoride is readily obtained. The gas was condensed in a trap cooled to − 160° C. and afterwards sublimed into an aspirator. The greater part of the small amount of selenium tetrafluoride collected remained in the trap after the selenium hexafluoride had sublimed. The product was scrubbed with 10 per cent sodium hydroxide solution, condensed in liquid air, and transferred to an evacuated steel cylinder cooled in 'Drikold'.

The vapour density of a sample of the purified gas, dried by sublimation *in vacuo* from a trap cooled to − 80° C., was determined by direct weighing and the molecular weight found to be 192·6 ± 1 (theoretical value, 192·96).

Hokhberg and Sandberg[3] have reported the dielectric strength of selenium hexafluoride to be nearly twice that of sulphur hexafluoride, giving the ratio 4·63 : 2·49 : 1 for the relative dielectric strengths of selenium hexafluoride, sulphur hexafluoride and air. Their measurements were carried out using two Rogovsky electrodes of 32 mm. diameter spaced at 2–8 mm. The maximum value of pressure × gap was 220 mm. mercury × cm., and the results were extrapolated to a value of 1 cm. at 1 atmosphere pressure. They make no mention of the method of preparation or of the purity of the gases tested.

The breakdown potential between two half-inch diameter brass spheres has been measured in selenium hexafluoride prepared as above, in sulphur hexafluoride containing not more than 41 p.p.m. of

RELATIVE BREAKDOWN VOLTAGES IN SELENIUM HEXAFLUORIDE, SULPHUR HEXAFLUORIDE AND AIR

| Pressure × gap mm. Hg. × cm. | Relative breakdown voltage | | |
|---|---|---|---|
| | $SeF_6$ | $SF_6$ | Air |
| 50 | 1·80 | 1·75 | 1 |
| 100 | 2·10 | 2·00 | 1 |
| 150 | 2·40 | 2·20 | 1 |
| 200 | 2·50 | 2·30 | 1 |
| 250 | 2·65 | 2·40 | 1 |
| 300 | 2·70 | 2·40 | 1 |
| 350 | 2·75 | 2·40 | 1 |

disulphur decafluoride and 12 p.p.m. of sulphur tetrafluoride, and in dry air. The relative breakdown voltages obtained using gaps of 0·05–8·6 mm. and pressures of ½, 1, 1½ and 2 atmospheres are shown in the accompanying table. Extrapolation of the results to a gap of 1 cm. at 1 atmosphere pressure indicates that the relative dielectric strengths of selenium hexafluoride to air and of sulphur hexafluoride to air are not greater than 2·9 : 1 and 2·4 : 1 respectively.

We have found selenium hexafluoride to be slightly soluble in alcohol and acetone, insoluble in 5 per cent aqueous sodium hydroxide solution, but soluble in 10 per cent alcoholic sodium hydroxide solution. It reacts slowly with mercury, forming mercurous fluoride, and reacts readily with a solution of sodium iodide in acetone:

$$SeF_6 + 6NaI \rightarrow Se + 6NaF + 3I_2.$$

No change in volume occurs after heating selenium hexafluoride to 500° C. for 10 min. in 'Pyrex' glass. At 700° C., reaction with the glass occurs.

We wish to acknowledge our indebtedness to Mr. G. H. F. Seiflow and Mr. J. Adams, who carried out the electrical measurements.

## Thermal Degradation of Polystyrene

THE degradation of polymers may be elucidated by various approaches; one of the more accessible routes is a study of the volatile degradation products.

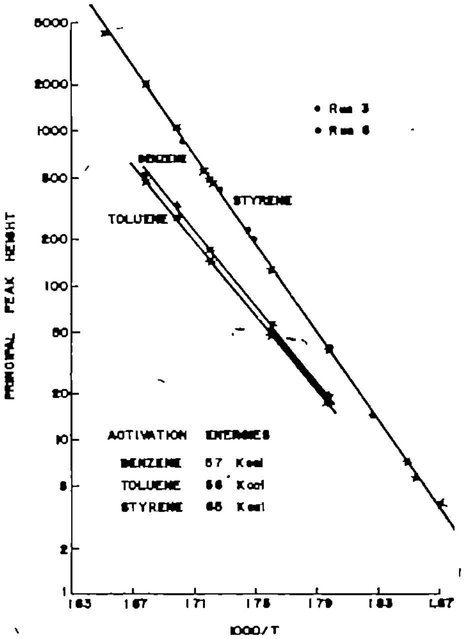
Grassie and Melville[1] measured the pressure of volatilized monomer (having determined the identity of the gas by other means) from heated polymethyl methacrylate in a continuously pumped system with a constriction limiting the pumping speed to a constant value. The measured pressure was directly proportional to the rate of production of monomer. This method has been modified by using a mass spectrometer instead of a Pirani gauge. The advantages of the mass spectrometer as the pressure gauge are: (*a*) it can analyse the gas produced; (*b*) it can measure each product independently; (*c*) it has great sensitivity.

Twenty-five milligrams of thermally polymerized styrene prepared by Dr. F. R. Mayo of this laboratory was deposited as a film over 150 cm.$^2$ of quartz by evaporation of the benzene solvent. This would leave a layer $1 \cdot 6 \times 10^{-4}$ cm. thick if uniformly distributed. The quartz tube (20 cm. long, 4 cm. diameter) containing the sample was sealed directly to the sample inlet tube of a General Electric analytical mass spectrometer. The sample inlet tube was the constriction limiting the flow through the ion source. It had a calculated conductance of approximately 0·012 litre sec.$^{-1}$ for styrene. The conductance of the pumping system beyond the ion source was of the order of 1,000 times greater. The maximum pressure in the spectrometer tube when rate measurements were made was $2 \times 10^{-7}$ mm.; hence the pressure of monomer in the sample tube was about $2 \times 10^{-4}$ mm.

The sample was given a preliminary degassing to remove solvent by pumping while heating at 80° C. for 4 hr. and at 30° overnight. The spectrometer, with the sample at 30°, had a very high background, with benzene predominating. The temperature of the sample was then increased at such a rate that the pressure in the spectrometer tube did not exceed $1 \times 10^{-6}$ mm. At the end of five hours the sample was at 110°, and benzene, methyl*cyclo*hexane, toluene, ethyl benzene and acetic acid comprised 95 per cent of the material evaporating from the sample. Within nine hours a temperature of 145° was reached, and acetic acid predominated in the volatilized materials. After sixteen hours at 145°, the rate of production of volatile materials dropped, permitting the sample to be heated to 210° before large amounts of acetic acid limited the rate of heating. A temperature of 220° was reached in three additional hours. Small amounts of styrene were then observed, along with other materials, the acetic acid having decreased. The temperature was increased by small steps which brought out more acetic acid at the beginning of the next three or four increments; benzene and toluene were also produced. A temperature of 310° was finally reached. At this temperature the polymer was decomposing, chiefly to styrene, benzene and toluene, but the rates of evolution decreased with time at any one temperature. The sample was then left at 230° for about seventy hours; at the end of this period there was no measurable evolution of gas. All the results noted up to this point were ascribed to adsorbed or dissolved impurities, or odd configurations present in small amounts. The total amount of material volatilized is estimated as less than 1 per cent of the sample. The persistence of the solvent, benzene, under conditions where 'molecular distillation' would remove it in an extremely short time, indicates another rate-limiting process. This indicated a phenomenon to be considered in other investigations of this kind. The presence of acetic acid and methyl*cyclo*hexane is unexplained. The early evolution of styrene (at 220°) may have been due to desorption of unreacted monomer or scission of loosely bound monomer.

Subsequent heating of the sample from 230° to the temperature-range 260°–330° C. at intervals extending over a period of ten days showed the rates of evolution of styrene, benzene and toluene to be functions of temperature only. This is believed to be decomposition of the polymer. A plot of principal peak heights for these three materials against the reciprocal of the temperature is reproduced herewith.

From the graph, the activation energies for the production of the various substances have been derived. It is seen that benzene and toluene have



the same activation energies (57 and 56 kcal.), within experimental error, and may be produced by similar mechanisms. The styrene has a distinctly greater activation energy (65 kcal.) and must be accounted for in another way.

The rate of production of styrene may be calculated if the signal height for a given rate of flow can be established[2]. This was determined, and it was found that a rate of 1·0 × $10^{-4}$ μlit./sec. gave a peak height of 960 units. Hence at 330°, 7·0 × $10^{-3}$ per cent of the sample will decompose per minute to styrene. Extrapolations of Madorsky's results[3] for higher temperatures would indicate a maximum rate of 4·0 × $10^{-2}$ per cent per min. at 330°. It should be pointed out that the results described here were obtained with less than 1 per cent of the total sample degraded, and the results were obtained in the temperature-range 260°–330°. Madorsky, working in the range 335°–365°, degraded a large fraction of the sample; hence, our results are not expected to be comparable. His value of 58 kcal. for the initial activation energy was deduced from measurements of loss of weight of the sample, as was the value of 44·7 found by Jellinek[4]. In the cases cited, the weights of volatilized materials were summed, instead of measuring the rate of volatilization of each substance.

In addition to styrene, benzene and toluene, small amounts of other substances were observed, the dimer of styrene being next in abundance. Higher temperatures would be required to get reliable values for the activation energies of these other materials. The very high molecular weight materials reported by Madorsky were not observed under these conditions of degradation and measurement.

The simpler case of polymethylmethacrylate was studied in the temperature-range 170°–210°, and an activation energy of 29·5 ± 1·0 kcal. was found for the production of the monomer, essentially in agreement with 31·0 kcal. found by Grassie and Melville[1]. The problem of removing solvent and other impurities were more acute in the case of methylmethacrylate; however, when they were removed, the monomer alone was produced.

The investigation is being extended to other systems, and detailed results and interpretations will be described elsewhere.

## Interaction of Manganous Ions with Enolase

MANY enzymes require the presence of metal ions for activity[1]. Kinetic studies on such systems indicate the existence of an equilibrium between the enzyme protein, the activating metal ion and a complex between metal ion and enzyme. By assuming the complex to be the only species catalytically active, a hypothetical dissociation constant can be determined from activity measurements. Considerations of this kind have led Smith[2] to formulate a theory of peptidase action according to which the metal ion acts as a binding group bringing enzyme and substrate together. Already in 1942, the same type of mechanism was suggested by Warburg and Christian[3] for the activation of enolase by magnesium, manganous and zinc ions. Since, however, no direct measurements of the interaction of activating metal ions with well-characterized enzyme preparations have been published, the present study was undertaken.

Enolase was purified by the method of Warburg and Christian[3]. These authors only investigated the activation by magnesium ions in detail, but the present work was extended to include the other activating ions. Fig. 1 shows the activity[3] of the enzyme as a function of the concentration of manganous ions measured in a 0·04-*M* phosphate buffer, *p*H 6·8. Employing the conventions of Warburg and Christian[3], the hypothetical dissociation constant of the enolase–manganous ion complex was calculated to be 2·5 × $10^{-5}$ mole/l. under the conditions used.

The interaction of manganous ions with enolase was also studied by the equilibrium dialysis technique[4]. Fig. 2 gives the average number of manganous ions bound per molecule of enzyme in 0·025 *M* phosphate buffer, at *p*H 6·8 and + 4°, as a function of the concentration of free manganous ions. The experimental points are too few to permit a detailed mathematical analysis, but they indicate that, in the range of concentration studied, the manganous ions

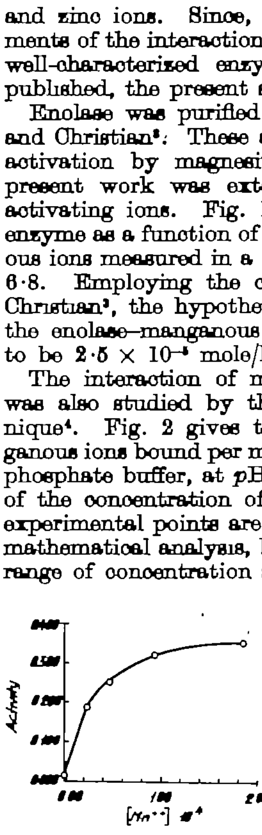

Fig. 1

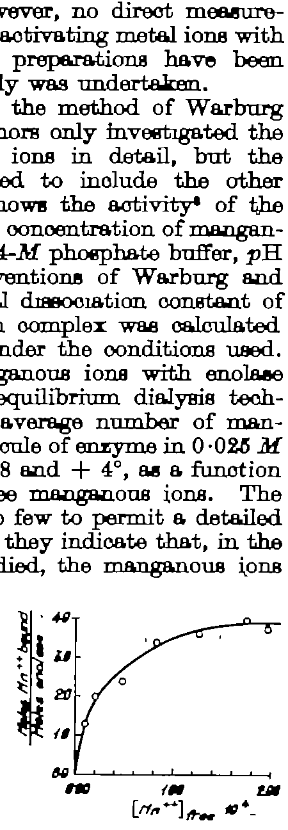

Fig. 2

Fig. 1. Influence of the concentration of manganous ions on the activity (arbitrary units) of enolase in 0·04 *M* phosphate buffer, *p*H 6·8

Fig. 2. Effect of the concentration of free manganous ions on the number bound by enolase in 0·025 *M* phosphate buffer, *p*H 6·8, at + 4°

interact with four groups of the enolase molecule, the overall dissociation constant being about $2 \times 10^{-4}$ mole/l., a value of the same order of magnitude as that calculated from the activity measurements.

If it is assumed that the four binding groups are identical and do not interact, the logarithm of the first association constant can be calculated and is 5·3. Thus, the interaction of manganous ions with enolase is stronger than that demonstrated with any amino-acid or simple peptide[4–7]. It is of interest to note that the enolase molecule contains eight sulphur atoms[3], since Cohn *et al.*[8] have recently suggested that cystine may furnish the complex-forming group in metal-activated enzymes.

The work described in the present communication is being extended and a detailed report will be published elsewhere.

I wish to thank Prof. Arne Tiselius for his interest in this investigation.

*Note added in proof*. Experiments on the activation of enolase by zinc ions, carried out since the above communication was submitted for publication, demonstrated a fall in activity at high metal ion concentrations. This led to a re-investigation of the activation by manganous ions, which showed that the data are more correctly interpreted by assuming two types of interaction between manganous ions and enolase, one giving an active complex and the other resulting in inhibition. If this inhibitory effect is taken into account, the hypothetical dissociation constant of the active complex is found to be $4 \cdot 4 \times 10^{-5}$ mole/l. (as compared with $2 \cdot 5 \times 10^{-4}$ mole/l. above), while that of the inactive complex is $2 \times 10^{-3}$ mole/l.

## A Biophysical Test for Aldohexoses

I HAVE observed that some sugars inhibit the flocculation of bottom-fermentation brewer's yeast in tap water, whereas others do not.

| Sugars which inhibit flocculation | Sugars not inhibiting flocculation |
|---|---|
| Glucose | Fructose |
| Mannose | Galactose |
| Maltose | Lactose |
| Sucrose (after interaction for some time) | Xylose |
| | Arabinose |
| | Dextran, etc. |

The flocculation is thus inhibited by aldohexoses. This fact can be used for a quick test for glucose in the presence of fructose. About 30 mgm. of freeze-dried brewer's yeast were suspended in 5 ml. of tap water. When held at rest, the yeast flocculates, and is precipitated within one minute. On addition of an equal volume of the solution under examination, the presence of the above aldohexoses is indicated by the fact that the yeast suspension remains stable for a longer time (some hours). The influence is distinct up to a sugar concentration of 0·1 per cent.

The pH of the solution should be kept in the range 4–7, and the temperature above 25° C. As a condition for flocculation is the presence of calcium or magnesium salts in the medium, anions giving undissociated salts with these metals, such as oxalate, fluoride, phosphate and carbonate, should be avoided.

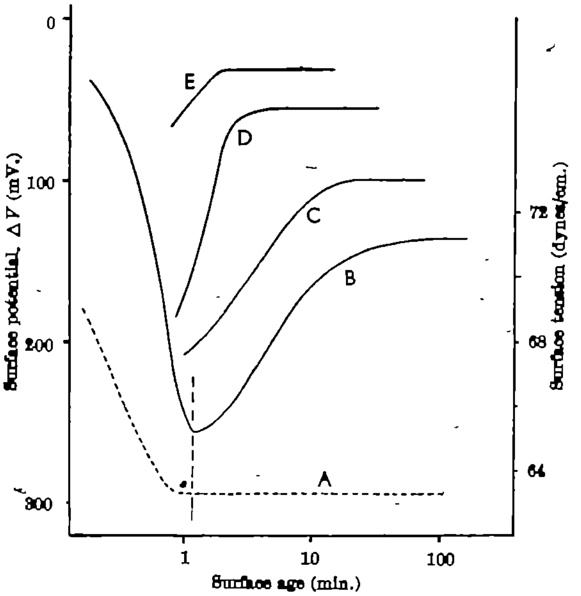
## Dynamic Potentials of Freshly Formed Liquid Surfaces

As a basis for the study of the adsorption of a surface-active solute to a fresh liquid surface, it is necessary to establish with accuracy the changes in the physical properties of the surface which occur immediately after its formation, and throughout the adsorption process. Two important properties, which undergo considerable change as adsorption proceeds, are the surface tension and the surface potential. We have recently observed that the surface potential of aqueous solutions of many long-chain compounds, at the instant when adsorption is complete, differs widely from the ultimate equilibrium value. The changes in potential following establishment of concentration equilibrium between surface and bulk solution are comparable in magnitude with those occurring during adsorption, and erroneous deductions may result from the assumption that dynamic surface tensions and potentials change in a similar manner with age of surface.

Measurements of the rate of change of surface tension in aqueous solutions of straight and branched-chain alcohols[1] have shown that the surface tension of such solutions is determined primarily by surface concentration of solute, and is little influenced by molecular orientation in the surface. Changes in dynamic surface tension therefore provide a satisfactory means of following the development of an adsorbed film; when concentration equilibrium is established, no further appreciable change in tension occurs.

Curves *A* and *B* in the graph compare the change in surface tension and potential respectively for a 0·00045 per cent aqueous solution of decyl alcohol at 15°. Whereas tension is constant after one minute, the potential shows a considerable rise after adsorption is complete. In interpreting these effects, we consider that adsorbing molecules of solute arrive at the surface in a disorientated state, and that the continual arrival of solute molecules maintains this disorientation throughout the adsorption process. Unlike tension, the surface potential is influenced greatly by surface orientation as well as by surface concentration; the potential of the surface when adsorption is complete is therefore characteristic of the disorientated film. The general use of the well-known expression $\Delta V = 4\pi n\mu$ in surface potential studies implies that the decrease in the air–water contact potential ($\Delta V$) is brought about by the solute only. However, it seems probable that the potential changes which follow adsorption are greater than can be attributed entirely to variations in the effective dipole moment $\mu$; it is therefore considered that water as well as solute molecules are disorientated by adsorption to fresh surfaces.

When the disturbing effect of adsorption is no longer operative, the film can become rearranged to



a stable configuration. An important observation in these experiments is that the time required for the orientation process is in all cases of a different order from that required for the initial adsorption. Curves *C*, *D* and *E* (and the accompanying table) show that the effect persists down to the shortest chain-lengths, and illustrate the increase in time of orientation with length of carbon chain.

| Curve | Alcohol | Concentration (%) | Adsorption time | Orientation time |
|---|---|---|---|---|
| *B* | *n*-Decyl | 0·00045 | 70 sec. | 30 min. |
| *C* | *n*-Hexyl | 0·020 | 0·065 sec. | 15 ,, |
| *D* | *n*-Butyl | 0·154 | < 0·005 ,, | 3 ,, |
| *E* | Ethyl | 0·385 | < 0·005 ,, | 1–2 ,, |

The term 'surface potential' has therefore no meaning without reference to the age and condition of the surface. For any given surface excess, there are clearly two limiting values, the 'disorientation' and 'orientation' potentials characteristic of the two limiting surface conditions; the measured potential may lie on or between these limits, depending on the particular solute used and its concentration.

The following example illustrates the significance of these observations. A new technique for the measurement of dynamic surface tensions has been described by Posner and Alexander[2], in which the authors measured the changes in potential along jets of *iso*-amyl and *sec*-octyl alcohol solutions and translated these potential values into dynamic tensions using calibration curves derived from equilibrium values of these two quantities measured under static conditions in a trough. The dynamic tensions so deduced showed considerable divergence from the values determined by Addison[3] from jet dimensions. Since the latter values have been employed in certain theoretical studies of the adsorption process[4], it is important to investigate this divergence. The results in the accompanying graph indicate that solute becoming adsorbed to the surface of a jet must be in a state of disorientation; it has been found that, when the potential values of Posner and Alexander are translated into dynamic tensions using the appropriate tension – disorientation potential calibration curves, the results obtained by the two techniques are in almost ideal agreement.

A full account of this work is being submitted for publication in the *Journal of the Chemical Society*.

## Identification of Radiosensitive Volume with Nucleic Acid Volume

On the basis of inactivation data for nearly two dozen plant, animal and bacterial viruses, Lea[1] pointed out that the radiosensitive or target diameter was within a factor of 2 of the physical diameter of nearly all the viruses studied, the agreement becoming poorer with increase in diameter. From this agreement Lea concluded that the small viruses must be composed almost exclusively of radiosensitive material which he identified with nucleoprotein. The very large viruses were stated to be more like ordinary cells in that they seemed to have an appreciable amount of relatively insensitive 'cytoplasmic' material. Other workers (for example, refs. 2 and 3) have given experimental reasons for believing that the nucleoprotein material is the radiosensitive portion of a cell.

The first purpose of this communication is to point out that Lea's interpretation of his results may be incorrect. The source of the error is the fact that a difference of a factor of 2 in diameter means a difference of a factor of 8 in volume. On this reasoning it is improbable, except for the very smallest viruses, that the entire virus can be considered to be radiosensitive. The question then arises as to what might be identified with the target, if, indeed, any single structure can be so identified.

My second purpose is to show that a more straightforward use of the radiation data gives quantitative support to the idea that the radiosensitive portion of a virus is its nucleic acid (not its nucleoprotein).

Both radiation data and nucleic acid data have been found for ten viruses. Radiation data for the four plant viruses and two of the three animal viruses in this group have been given in ref. 1 along with the size of virus. Radiation data for the three bacterial viruses are given in ref. 2. The inactivation data for influenza are given in ref. 4. Nucleic acid data for the bacterial viruses are given in refs. 5, 6 and 7; for the remaining viruses in ref. 8. Virus densities are given in ref. 10, except for tobacco necrosis, tobacco ringspot, and vaccinia viruses; the latter were assumed to have densities of 1·3 gm./ml. The nucleic acid density was taken[9] as 1·63 gm./ml. The results of the calculations of radiosensitive volumes and nucleic acid volumes are given in the accompanying table.

It is evident that there is a good agreement between target volume and nucleic acid volume except for the largest two viruses (influenza and vaccinia); these are well known to have complex internal structures which could easily make inapplic-

| Virus | Target volume $(10^6\ m\mu^3)$ | Nucleic acid volume $(10^6\ m\mu^3)$ |
|---|---|---|
| Tobacco mosaic | 2·4 | 2·5 |
| Tobacco necrosis | 1·3 | 1·2 |
| Tobacco ringspot | 1·9 | 1·2 |
| Tomato bushy stunt | 2·0 | 1·8 |
| Coliphage *T2* | 56 | 86 |
| Coliphage *T6* | 56 | 86 |
| Coliphage *T7* | 27 | 26 |
| Influenza | 55 | 21 |
| Shope papilloma | 2·1 | 4·2 |
| Vaccinia | 13 | 194 |

able the single-target, single-hit theory used in the calculations. It should be emphasized that the uncertainties in the data are sufficiently large for the agreement between target volume and nucleic acid volume to be well within probable error. Similarly, of course, it cannot be excluded that the volumes could be different by, perhaps, a factor of 2.

It was not possible to use the data on nucleic acid contents of four other bacterial viruses given in ref. 9, because some of the resultant nucleic acid volumes are greater than the entire volumes of the viruses.

This investigation was supported by the Atomic Energy Commission under Contract No. AT(30-1)-913.

## Luminosity generated by Shock Waves

Luminous phenomena accompanying shock waves have been observed under extreme conditions by Michel-Lévy, Muraour and Vassy[1] through head-on collision of shocks generated by explosives, and by Perry and Kantrowitz[2] at the point of convergence of a cylindrical shock wave. A related phenomenon is observed in the gas discharges of Fowler, Goldstein and Clotfelter[3], although the creation of the shocks in this type of work is of an electrical nature and does not immediately allow a hydrodynamic interpretation.

It was noticed some time ago that the University of Michigan shock tube exhibits luminosity in gases such as air, nitrogen and argon. This shock tube[4] has a rectangular cross-section of 2 in. × 7 in., a compression chamber 7 ft. long and an expansion chamber of 18 ft. Shocks are produced in the expansion chamber by rupturing a diaphragm between it and the compression chamber, which generally contains hydrogen at a pressure of several atmospheres. Preliminary results of our investigation were reported at the Salt Lake City meeting of the American Physical Society in June 1952. At that time experiments were also reported by Kantrowitz which, although different substances were used, seem to show very similar results. In what follows, further experimental investigations are reported.

Luminosity is observed when the shock is reflected normally from a plate at the end of the tube. In order to localize this phenomenon within the space-time events taking place in the shock tube, wave-speed camera exposures were taken of the region near the reflecting plate. This established with complete certainty the fact that the luminosity is confined at first to the region between the reflecting plate and the reflected shock, until the latter meets the interface or cold front which divides the gases initially in front of and behind the burst diaphragm. From then on, the luminous region is limited by the end plate and by the expansion wave generated at the meeting of the reflected shock and the interface. The wave-speed camera pictures show a roughly triangular region, the entire duration of time of the phenomenon being between 1,500 and 3,000 microsec., depending upon the strength of shock and the nature of the gas.

Spectroscopic investigation has been carried out with a two-prism glass spectrograph, which has a dispersion of 12 A./mm. at 4000 A. and of 140 A./mm. at 9000 A. Preliminary exposures with nitrogen and argon showed merely the *D* lines of sodium and the *g* line ($^1S - {}^1P$) of calcium. According to hydrodynamical reasoning, stronger shocks with correspondingly higher temperatures can be obtained, for given pressures in front of and behind the diaphragm, when using heavy monatomic gases. Therefore krypton and xenon (we are indebted to the Linde Air Products Co., Tonawanda, N.Y., for a generous gift of rare gases) have recently been used. The following table shows the theoretical temperatures attained with three atmospheres of hydrogen in the compression chamber and the indicated pressures of xenon in the expansion chamber after reflexion of the shock from the end plate.

| Xenon pressure | Temperature |
|---|---|
| 32·4 mm. mercury | 6,000° K. |
| 17·8 " " | 9,000 |
| 5·7 " " | 18,000 |

The actual temperatures are, because of viscosity and radiation losses, somewhat lower. The last pressure and temperature just about represent the working limit of the present shock tube.

It is now possible to make a comparison of the intensity of the *g* line of the neutral Ca with that of the *H* and *K* lines of Ca II as the temperature increases. While for weaker shocks the *g* line alone is present, for stronger shocks the *H* and *K* lines increase in strength, with the *g* line even diminishing its intensity. This behaviour conforms to the theory of stellar atmospheres put forward by Saha, Fowler and Milne[5]. It is thus established that the luminosity of the gases behind shocks is purely a temperature phenomenon. Especially at lower shock-strengths, metallic lines are of greater prominence than the lines of the carrier gases, similar to the conditions in stellar atmospheres. Thus several hundred lines of sodium, calcium, barium, iron, aluminium, as well as bands of calcium, are observed which are due to room dust and to the walls of the tube. Further, by introducing the acetyl acetonate of copper the spectral lines of this metal were observed.

As to the lines of the carrier gas, it is obvious that xenon offers the most favourable conditions not only because of the higher temperatures attainable but also because of its comparatively low excitation potential. Indeed, at calculated temperatures above 12,000° K., xenon lines are first observed. With a single flash produced by a shock of calculated temperature 18,000° K., about fifty xenon lines below 9000 A. have been identified. These are all the lines obtainable with a xenon-filled Geissler tube after an exposure of about 2–5 min. Comparison of the xenon lines produced in these two ways appears to indicate a broadening and, in some cases, a shift—effects which were announced by Kantrowitz. In view of the results of Michel-Lévy, Muraour and Vassy and also of Schulz[6], there seems little doubt that, as the strength of the shocks increases, continuous spectra will play a more and more important part.

It is intended to apply quantitatively the theories of Saha, Fowler and Milne with the purpose of determining the degree of ionization and the electron pressure at various shock strengths. The investigation of the shapes of spectral lines under these novel conditions of rapid pressure and temperature changes should complement the information gained from astrophysical and electrical discharge studies. Like the *Schlieren* and shadowgraph methods, observation of luminous phenomena will give information on the flow of a supersonic gas stream around a model. As the incoming flow is deflected or reflected by a model, the luminosity distribution will furnish a measure of the local temperature.

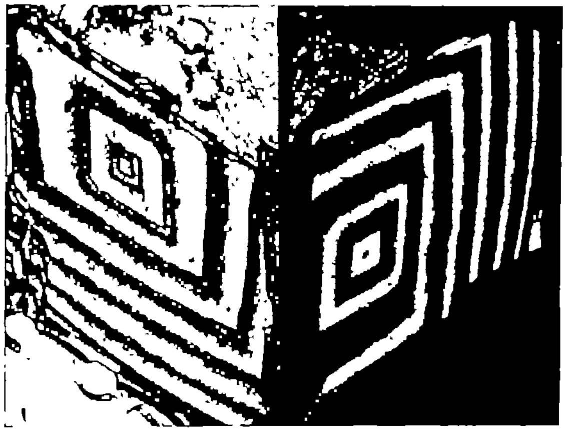
## Transmission-like Reflexion Fringes in Birefringent Crystals

IT has long been known that the suppression of the first beam in multiple-beam reflexion interference fringes produces a transmission-like pattern. This was established in 1907 by Lummer[1], and was recently applied by Bruce[2], who cut out the first beam by a knife edge. In high-magnification studies, this obscuration of the lens may lead to diffraction anomalies (Tolansky[3]).

In the special case of thin birefringent crystals, transmission-like systems can be obtained in reflexion by a simple optical device. If a birefringent tabular crystal is grown on a silvered optical flat and the upper surface is then silvered, we have a birefringent medium between silvered surfaces capable of producing familiar multiple-beam localized Fizeau fringes, and in reflexion such a system gives dark fringes on a bright background. Fig. 1 gives an example using the crystal stearic acid. Owing to birefringence the fringes are double, the components being mutually perpendicularly plane polarized. However, if illuminated with plane-polarized light and the reflected system is viewed through an analyser, it is clear that, without any change of the numerical aperture, the first reflected beam can easily be cut out, since this is the only beam in the interference system which does not go through the crystal, and hence its plane of polarization differs from that of the complete multiple-beam system. Fig. 2 shows the appearance of the pattern obtained by thus suppressing the first beam. Here the two components are polarized in the same plane. It is clear that this simple technique permits not only the total suppression of the first beam but also its partial suppression if wished. Hence it is possible to study systematically the continuous change in the appearance of the fringe pattern as the contribution of the first beam is successively varied.



Magnification × 200

Detailed analysis of the system will be published elsewhere.

I wish to thank Prof. S. Tolansky for his interest and Miss P. M. Reynolds for valuable discussion. This work is being done during the tenure of an I.C.I. Fellowship while on study leave from the University of Delhi.

## Relationship between Relative Viscosity and Volume Concentration of Stable Suspensions of Spherical Particles

MANY relationships have been suggested for the relative viscosity, $\eta_r$, of a suspension of rigid, smooth spheres in a liquid in terms of the volumetric concentration $c$. Einstein[1] obtained the equation:

$$\eta_r = 1 + 2\cdot 5c,$$

for a suspension of spherical particles at infinite dilution and devoid of such influences as agglomeration, solvation, accumulation of electric charge and so forth. Other equations and empirical relationships have also been derived by different workers.

In recent work we have found it convenient to plot the value $1 - \frac{1}{\eta_r}$ against the volumetric concentration $c$ for stable suspensions of spheres, and have obtained a straight line. The results of other workers were treated in this way, the data used including those obtained from rising sphere, rotating cylinder and capillary tube viscometers. In most cases a straight line has been obtained up to concentrations of at least 20 per cent (the highest concentration used in some of the investigations), although the data given for the suspensions of glass spheres used by Vand[2], and by Eirich, Bunzl and Margaretha[3], gave lines which curve towards the concentration axis and which closely resemble curves we have obtained for unstable suspensions.

The equation to the straight line may be written

$$1 - \frac{1}{\eta_r} = kc,$$

that is, $\eta_r = \frac{1}{1 - kc}$ or $\eta_r = 1 + kc + k^2c^2 + k^3c^3 \ldots$,

where $k$ is a constant. At extremely low concentrations the expression reduces to

$$\eta_r = 1 + kc,$$

which, if $k = 2{\cdot}5$, is identical with Einstein's equation.

The accompanying table shows the values of $k$ obtained from curves for the data of various workers.

| Worker | Type of viscometer | Size ratio of suspended spheres | $k$ | Range of volumetric concentration over which equation applies (per cent) |
|---|---|---|---|---|
| Eirich, Bunzl and Margaretha (ref. 3) | Capillary | * | 2·41 | 0–15+ |
| Broughton and Windebank (ref. 4) | Rotating cylinder | 2·0 : 1 | 2·57 | 0–15+ |

## A Theoretical Approach to the Problem of determining the Relationship between the Constants of Circuits and their Intrinsic Safety

There is an urgent need for a comprehensive theoretical correlation between the constants of a complex circuit and its intrinsic safety in the presence of inflammable gases. This has not yet been attempted owing to the lack of knowledge of the fundamental mechanism of spark ignition. I believe, however, that even in the present state of knowledge it is possible to derive a circuit theory which would permit the approximate correlation between intrinsic safety and circuit constants however complex the circuit may be.

The available evidence suggests that the principal factors controlling ignition are the nature, composition, ambient temperature, pressure and turbulence of the inflammable gas; the material, configuration and manner of separation of the electrodes; the energy dissipated in the discharge and its duration; and the volume of gas influenced by the discharge. What, in fact, appears to matter is that the temperature of a sufficient volume of an inflammable gas be raised above some critical level. Thus, for a particular inflammable gas under specified conditions and for a specified electrode system, a certain minimum amount of energy must, it seems, be imparted to the gas. This energy is the difference between that supplied by the discharge and that removed to surrounding space.

The expression for energy expended in a discharge through an opening current-carrying switch is, in operational notation,

$$U = \int_0^T [Z_p (I - i)\, i \, . \, 1]\, dt,$$

where $I$ is the initial current through the switch before it starts opening at time 0; $i$ is switch current at any time $t$ between 0 and $T$; $T$ is duration of discharge; $Z_p$ is impedance across the open switch when all sources of voltage are short-circuited.

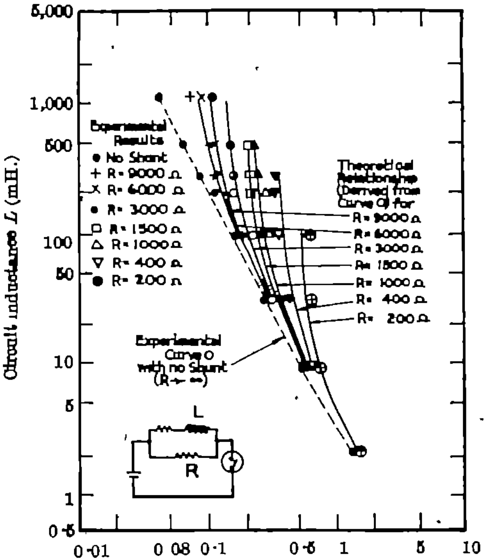

Fig. 1. Comparison between experimental results obtained by the Safety in Mines Research Establishment and the theoretical relationship derived from the curve O for the effect of shunt resistance on minimum igniting current

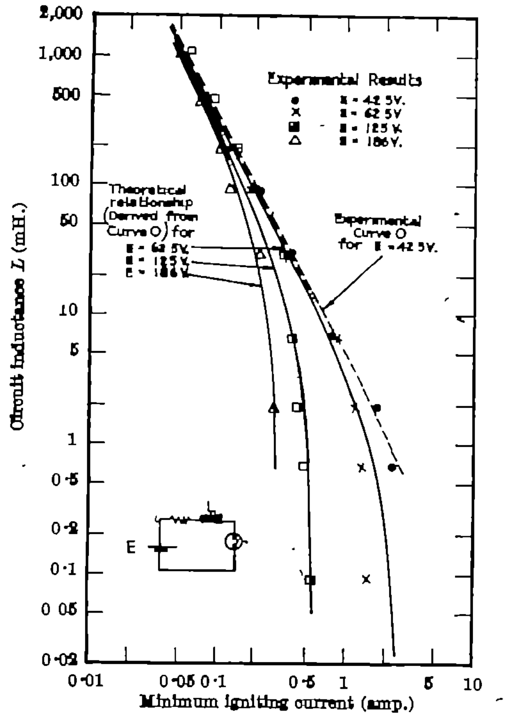

Fig. 2. Comparison between experimental results obtained by the Safety in Mines Research Establishment and the theoretical relationship derived from curve 0 for the effect of battery voltage on minimum igniting current

This energy $U$ can be computed for any linear circuit, whatever its voltage and impedance, so long as the duration of the discharge and the manner in which current $i$ varies are known. Non-linear circuits, such as iron-cored inductors, rectifiers and non-linear resistors, can also be treated similarly.

The above theoretical considerations were checked for non-capacitative circuits against results of tests with an 8·3 per cent methane–air mixture published by the Safety in Mines Research Establishment[1]. In the absence of information regarding current and voltage patterns or the duration of discharges obtained in the tests, the following assumptions were made: (1) constant rate of current decrement; (2) constant duration of discharge (of magnitude derived from a few test results) for each electrode system and rate of separation; (3) constant fraction of energy of a discharge employed in igniting the gas for each electrode system and rate of separation.

On this basis and adopting the concept of constant minimum igniting energy for a particular gas, electrode system and time of discharge, minimum igniting currents were computed for the effects of circuit inductance, shunt resistance and circuit voltage.

The computed results for the effects of shunt resistance and circuit voltage were compared with corresponding test results in Figs. 1 and 2 respectively. It can be seen that, even with the scant test information available at present regarding characteristics of discharges obtained, it was possible to predict the approximate point of ignition of the majority of circuits tested on the basis of information derived from a small fraction of the circuits.

Additionally, the test results for the effect of inductance in a series inductive-resistive circuit were shown to be predictable from a single test result. Finally, the effect of the rate of electrode separation reported by the Safety in Mines Research Establishment was shown to be consistent with the proposed theory.

A close agreement has thus been demonstrated between the calculated and the existing test results. New experimental work will be required to determine whether refinements of the theory are necessary to take account of additional factors, such as the recovery transient, the arc voltage or the ionization voltage; or whether, for example, a closer approximation to actual conditions is obtained if the voltage of the discharge is taken as constant or linearly rising and the discharge current is re-calculated from the above basic equation. It is proposed to publish a full report of this work elsewhere.

Thanks are due to the Director-General of the Scientific Department of the National Coal Board for permission to publish this account, and to Mr. D. R. Scott for his assistance in mathematical calculations.

## Conversion of Solid into Ascites Tumours

Previous studies by different authors[1-6] have shown the possibility of the conversion of solid into ascites tumours. Further observations have revealed information which promises to elucidate the nature of this conversion. In all, forty-two different mouse tumours have been tested so far.

The following procedure was used throughout. Solid tumours of various origin (Table 1) and, in most cases, homologous to one of a number of inbred mouse strains (*C3H*, *C57* black, *C57* leaden, *dba*, *Ak*, Strong *A*) were minced mechanically and 0·2–0·5 gm. of the fresh tumour pulp was injected intraperitoneally into mice belonging to the strain of origin or suitable *F*1 hybrids. The tumour was then maintained by successive intraperitoneal transfers for at least ten, but in most cases up to thirty to forty, transfer generations. While carrying out successive transfers, inoculations of peritoneal exudate in 0·4-ml. amounts were made whenever an exudate was present in appreciable amounts. If no exudate was available, solid-tumour mince was again used.

Table 1 lists the different tumour lines used with respect to their capacity for growing as typical ascites tumours. In agreement with previous definitions[3,4],

Table 1. Tumours Grouped According to Type

| Tumour type | Total number | Transformation into ascites tumour | | |
|---|---|---|---|---|
| | | Successful immediately | Successful gradually | Unsuccessful |
| Spontaneous mammary adenocarcinoma | 17 | 0 | 0 | 17 |
| Transplanted mammary adenocarcinoma | 6 | 0 | 4 | 2 |
| Transplanted sarcoma originally induced | 4 | 0 | 2 | 2 |
| Transplanted sarcoma originally spontaneous | 4 | 1 | 0 | 3 |
| Transplanted lymphoma | 5 | 5 | 0 | 0 |
| Transplanted melanoma | 2 | 0 | 0 | 2 |
| Transplanted hepatoma | 2 | 0 | 0 | 2 |
| Transplanted neuroblastoma | 1 | 0 | 0 | 1 |
| Transplanted chondrosarcoma | 1 | 0 | 0 | 1 |
| Total | 42 | 6 | 6 | 30 |

the term 'ascites tumour' is used for denoting the condition when intraperitoneally injected tumour cells primarily start multiplying in the peritoneal fluid, induce accumulation of ascites and eventually reach there a high concentration. The final stage represents a nearly pure culture of free tumour cells.

The tumours used fall into three different categories as regards their ability to grow as ascites tumours. Some of them give rise to typical ascites tumours immediately after their first intraperitoneal inoculation. All five lymphomas tested and one out of eight transplanted sarcomas fall into this group. Other tumours showed a more gradual transformation and resulted in typical ascites tumours after a number of exudate-transfer generations only. These two categories were already recognized when our previous experiments were reported[3]. The number of transfer generations was, however, too small to permit definite conclusions as to the third category, which included tumours that gave negative results and grew only in the form of solid neoplasms. On the basis of examination of a larger number of tumours and a more prolonged observation period, it can now be stated that, under the conditions used, a number of tumours did not lend themselves to transformation into ascites tumours. This is at variance with the opinion of Goldie *et al.*[6], that cells from any mouse tumour strain inoculated into the peritoneal cavity can induce the accumulation of fluid and multiply therein as free cells.

The question arises as to the factors concerned in determining whether the tumour cells injected can proliferate freely in the peritoneal fluid and provoke ascites production. If the tumours used are classified according to the median survival time of animal groups receiving intraperitoneal inoculations of 0·2–0·5 gm. of minced solid tumour (Table 2), it will be seen that transformation into ascites tumour occurs only with the rapidly growing tumours, although even here not invariably. Moreover, the tumours belonging to these rapidly growing categories were all highly anaplastic and had previously passed through a long series of transfer generations before being used for the present experiments. It would appear that a rapid growth-rate and/or high degree of anaplasticity of the tumour tested are necessary, but in itself not sufficient conditions for the final attainment of the ascites tumour condition.

The capacity to induce the production of ascites and to grow in this ascites are thus shown to be the attributes of certain tumour cells only. In all five lymphomas tested, and in one of the sarcomas, such an ability seems to be inherent in a large proportion of the cell population, thus making transformation into ascites tumour instantaneous. On the other hand, in the tumours that show transformation of the gradual type, this property may perhaps be associated with a small number of cells only. These cells, possibly arising by mutation, would then be selected during the successive exudate-transfer generations, where the particular cells that can survive in the fluid will always be the transmitters of the tumour. Alternatively, the transformation may be viewed as an adaptive change, in which case there would be a given chance for each cell in the original population to survive and proliferate in the fluid exudate. If the former concept is true, then an ascites tumour, when once established, should retain its capacity for growing in the ascites form immediately and at any time, even if kept routinely by subcutaneous solid transfers. The following experiment shows that this is the case for one of the tumours used.

Table 2. TUMOURS GROUPED ACCORDING TO THE MEDIAN SURVIVAL TIMES OF INTRAPERITONEALLY INOCULATED ANIMALS

| Median survival time in days | Total number of tumours tested | Transformation into ascites tumour | |
|---|---|---|---|
| | | Successful | Unsuccessful |
| 6–10 | 7 | 5 | 2 |

Table 3. COMPARISON BETWEEN THE EFFECT OF INTRAPERITONEAL INJECTIONS OF SOLID KREBS 2 TUMOURS OF THE ORIGINAL SOLID STRAIN (*SS* STRAIN) AND THE STRAIN DEVELOPED BY SUBCUTANEOUS INJECTION OF THE KREBS 2 ASCITES TUMOUR AND KEPT AS SOLID TUMOUR FOR TWELVE TRANSFER GENERATIONS (*AS* STRAIN)

| | No. of animals inoculated | No. of animals developing only solid tumours | No. of animals forming ascites | Average percentage of tumour cells in ascites |
|---|---|---|---|---|
| *SS* strain | 9 | 8 | 1 | None detected |
| *AS* strain | 10 | 0 | 10 | 78 |

The Krebs 2 tumour (belonging to the category showing gradual transformation into ascites tumour[4,5]) has been kept in the ascites form for more than twenty intraperitoneal transfer generations. When 0·2 ml. of ascites was injected subcutaneously into *C3H* mice, solid tumours developed at the place of inoculation. Subcutaneous transfers of the solid tumours were then made by the trocar technique through twelve transfer generations. At the end of this serial transfer the tumours belonging to this line (*AS* strain, Table 3) were broken up, and 0·5 gm. solid-tumour mince was inoculated intraperitoneally to ten *C3H* mice. These inoculations provoked typical ascites tumours immediately in all animals injected, the frequency of the tumour cells in the ascitic fluids ranging from 67 to 92 per cent. This behaviour was in marked contrast to that of the original solid tumour[4] (*SS* strain, Table 3), which, on its first intraperitoneal transfer in comparable amounts, gave rise exclusively to the solid type of growth. This observation indicates a difference between the original cell population of the solid tumour and that of the solid-tumour line developed from the ascites in its relationship to growth as ascites tumours. In the line developed from ascites, this capacity was retained through twelve subcutaneous transfers, during which the cells grew in the form of solid tumours. This favours the possibility that one or several 'mutants' possessing this capacity were selected during the original procedure of transformation into ascites tumour, rather than the assumption that the transformation represents an adaptation to the fluid environment, in which case a reverse change might be expected to occur during the subcutaneous transfer generations. Experiments are now in progress for further elucidation of the question.

These investigations have been made possible by grants from the Wallenberg Foundation, Kooperativa Kvinnogillesförbundet and the Swedish Cancer Society.

## An Action Potential from the Motor Nerves of the Jellyfish *Aurellia aurita* Lamarck.

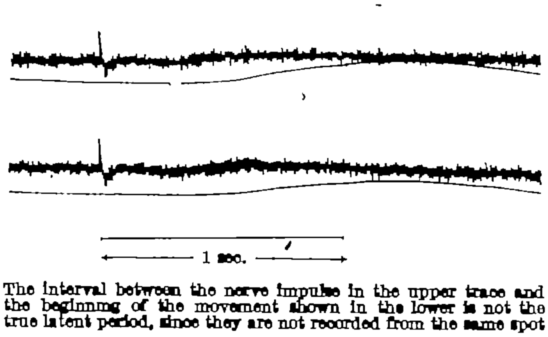
So long ago as 1878, E. A. Schafer demonstrated in *Aurellia* a network of bipolar and tripolar nerve cells the processes of which run in all directions, frequently coming close together at points which have been interpreted as synapses[1,2]. Using Holmes's method of silver staining, I have been able to confirm this histological picture; moreover, the fibres are similar to those of the through-conducting system in the mesenteries of *Metridium*[3]. These fibres can be seen clearly in living *Aurellia* under phase-contrast or oblique illumination.

It has long been known[4] that a bridge of tissue between two pieces of *Aurellia* will conduct a stimulus in either direction, resulting in a contraction in each piece. The ability to see the fibres has made it possible to show that this transmission can occur in either direction even when only a single fibre crosses the bridge. Such conduction does not occur when no nerve fibre can be observed under phase-contrast illumination.

Physiological work has shown[3] that there is a through-conducting system in Cœlenterates which behaves in the same way as the nerves of higher animals. The existence of an all-or-nothing response and a refractory period is characteristic of nerve fibres. The above experiment with *Aurellia* shows that the observed nerves are carrying the excitation. Formerly, there was no rigorous proof of this. It is to be expected, therefore, that one or more impulses with action potentials are propagated through at least some of the fibres at each contraction wave. Direct recording from a living nerve shows that this is actually so.

The fibres of the motor nerve net can be picked up individually with a single electrode of thin platinum wire mounted on a micro-manipulator. With a condenser-coupled amplifier of long time-constant, such a preparation gives one action potential at each spontaneous beat of the bell (see traces reproduced herewith). A majority of fibres tested do not show this action potential; but one cannot distinguish between fibres that have been damaged by the manipulation and those that may be inactive.

A single electrical stimulus applied to the subumbrella surface gives rise to a contraction of the muscle, and the spread of the contraction to every part of the bell is consistent with the histological arrangement of a network of nerves. In these and other experiments I can find no evidence of polarization, interneural facilitation, or decremental conduction in this motor system of *Aurellia* except occasionally in narrow bridges where it may be due to damage. Direct recording of the impulse in a single nerve fibre shows that the excitation, which can travel in all directions, consists at each beat of a single impulse at any point. This fact gives rise to important conclusions which will be discussed in a later paper.



The interval between the nerve impulse in the upper trace and the beginning of the movement shown in the lower is not the true latent period, since they are not recorded from the same spot

There is evidence, especially in other Scyphomedusæ, that an excitation can be transmitted across the subumbrella without giving rise to movement *en route*, and presumably this must go through some diffuse system other than the motor fibres. There is not sufficient evidence to extend these conclusions concerning *Aurellia* to groups other than Semæostome Scyphozoa.

## Competitive Suppression of Prototrophs

IN a recent publication[1], Jinks has compounded the erroneous impression, first given by Grigg[2], that competitive suppression is a neglected source of error in studies of prototrophs or reversions of nutritional requirement in micro-organisms. Køhmark and Westergaard[3] have shown that Grigg's criticism is inapplicable to their case; but since Jinks's publication is subsequent to this, and expresses the belief that "it is not easy to see a simple way of avoiding [the] effects" of competitive suppression, a brief recollection of the facts published elsewhere on the matter seems called for. Competitive suppression is certainly a real phenomenon and has been studied experimentally in some detail[4-6]. The findings relevant to the present issue are that: (1) the addition of prototrophs to the culture of organisms from which prototrophs it contains are being screened measures the extent of competitive suppression; (2) when competitive suppression is not acting, dilution of the culture results in a corresponding decrease in the number of prototrophs, and added prototrophs are recovered.

In Nelson's[7] studies of recombination in *E. coli*, the recovery of added prototrophs showed that competitive suppression was inoperative in a majority of crosses. In that cross in which the parents seemed to prevent the formation of colonies by the prototrophs formed, added prototrophs were not recovered. In these cases, however, suppression was exhibited only in concentrations far beyond those usually employed. Newcombe and Nyholm[8], for example, used smaller concentrations, in the range where limited testing showed ten-fold dilutions to give ten-fold decreases in numbers of prototrophs plated (Newcombe, personal communication). Similar consistent relationships between dilution and number of mutants were found in the work of Newcombe and Hawirko[9] on streptomycin resistance in *E. coli*. Moreover, in their publication they presented evidence for the recovery of added mutants in a background of parents more concentrated than that used in their determination of mutation-rates.

Similarly, studies on the reversion of biochemical mutants of *Neurospora crassa* have been performed under conditions where competitive suppression is absent. Giles[10], whose report on this point was presumably not available to Grigg, has shown by the addition of prototrophs that the parental conidia did not prevent their expression. The results of Grigg's experiments appear to be a function of starvation conditions, as Kølmark and Westergaard have claimed. McElroy (personal communication) finds that, even when sorbose is used, competitive suppression does not operate when the agar plates are as thick as those used in his previous experiments[11].

It is no doubt correct to demand that the reliability of the screening method employed be established in each case. In spite of what has been said above, one may still ask whether mutants of recent origin differ in no way from those somewhat older or whether, as Nelson suggests, the reaction-rate constant of bacterial recombination should be used instead of the empirical frequencies of prototrophs. But it is wrong to imply that laboratory workers in this field do not appreciate and have not studied the rôle of competitive suppression.

## The Mitochondrial Membrane

THE mitochondrial membrane has been a subject of controversy. Two distinct problems have arisen: whether a morphological membrane exists, and, if so, whether it is semi-permeable.

As Hogeboom and Schneider[1] point out, a number of workers, starting with Claude and Fullam[2], have interpreted structures seen in electron micrographs as mitochondrial membranes. Mühlethaler, Müller and Zollinger[3] observed such a membrane and estimated its thickness to be 200 A. Harman[4], however, doubted the existence of a membrane and considered that "it is acceptable on all available evidence to regard mitochondria as tightly coiled or compact gels".

The illustrations reproduced here show mitochondria from red beet tissue prepared in two different solutions, 30 per cent sucrose and 0·45 per cent potassium chloride, by the usual methods of centrifuging. Drops of the mitochondrial suspension were placed on electron microscope specimen screens and fixed; after drying, the soluble materials were removed by diffusion into water through the collodion membrane. The preparations were shadowed with uranium. The particles prepared in 30 per cent sucrose appeared as compact spheres 0·7–1·0 μ in diameter (Fig. 1). The particles prepared in 0·45 per cent potassium chloride appeared as large diffuse disks, 1–2 μ in diameter (Fig. 2). The same extracts under a phase-contrast microscope showed, in sucrose, compact spheres, and in potassium chloride, larger spheres with uneven patches, closely resembling the animal mitochondria prepared in potassium chloride by Zollinger[5]. The appearance of our preparations suggested uptake of water by the particles prepared in the solution of low osmotic pressure. Fig. 2 would be consistent with collapse of these particles from a sphere to a disk on drying. The disks show distinct folds or crinkles; from the length of the shadows the thickness of the membrane is of the order of 270 A. The appearance of the particles in water as swollen spheres which disintegrate after a time is evidence against the possibility that the membrane could have been formed while the particles were drying, and we conclude that these mitochondria have morphological membranes.

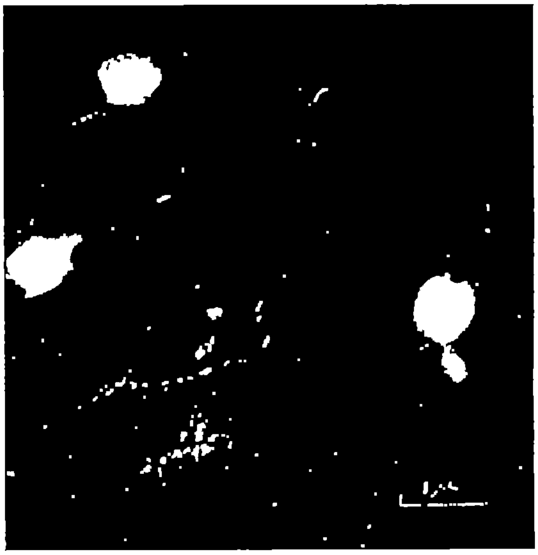

Fig. 1. Electron micrograph of beet mitochondria prepared in 30 per cent sucrose solution, fixed with formalin and shadowed with uranium; ratio of shadow length to particle height, 4 to 1

Fig. 2 shows a distinct membrane on a plant mitochondrion, thereby establishing beyond all doubt the suggestion made originally by Bucholz[6] and the inter-

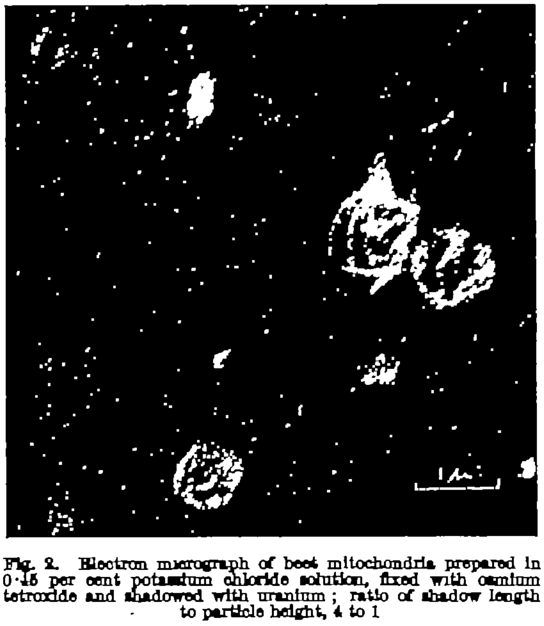

Fig. 2. Electron micrograph of beet mitochondria prepared in 0·45 per cent potassium chloride solution, fixed with osmium tetroxide and shadowed with uranium; ratio of shadow length to particle height, 4 to 1

pretation of the pictures published by Stafford[7] and Anderson[8]. Whether the membrane has semi-permeable properties and is responsible for the osmotic properties of the particle must still be investigated.

## Fixation of Bacterial Products by Erythrocytes *in vivo* and by Leucocytes

IT is known that, under suitable conditions *in vitro*, certain substances of bacterial origin may become fixed on to the surfaces of erythrocytes of various mammalian species, rendering the cells susceptible to agglutination by the specific antibacterial serum (see refs. 1, 2). The term 'hæmosensitin' has been suggested for substances which sensitize erythrocytes in this way[3]. This phenomenon has found important practical application in serological technique; but little work has been reported on the mechanism of the fixation process, or on its possible significance in relation either to bacterial disease, to hypersensitivity, or to normal cellular physiology. In this connexion, we have considered it of interest to investigate whether hæmosensitization can take place *in vivo*, and also whether mammalian cell types other than erythrocytes can fix the hæmosensitins.

A polysaccharide preparation ($S_t$) made from tuberculin by Lamensans, Grabar and Bretey[4] was used as a source of hæmosensitin in these investigations. Antiserum was obtained from rabbits after repeated injections of phenol-killed tubercle bacilli. All sera were heated at 56° C. for 30 min. and afterwards absorbed with an excess of guinea pig erythrocytes before use.

In connexion with the possibility of hæmosensitization existing *in vivo*, it is worth mentioning that *in vitro* the reaction is known to take place much more rapidly at 37° C. than at room temperature, and that it is negligible at 0–4° C. The following experiment was designed to show whether, in fact, the reaction can take place in the animal body. A number of guinea pigs (average weight, 300 gm.) were injected intravenously with different quantities of the polysaccharide ranging from 1 to 20 mgm. dissolved in 2 ml. saline. The controls received saline alone. After three hours, blood was taken from the heart into a sodium citrate solution, washed six times in saline, and the erythrocytes exposed to dilutions of the antiserum and of normal rabbit serum. The antiserum was found to agglutinate the erythrocytes taken from animals which had received 10 and 20 mgm. of polysaccharide, but not those from animals which had received 5 mgm. or less. Erythrocytes taken three days later from the animals which had received 20 mgm. were still sensitive to agglutination, although a higher concentration of antiserum was necessary to produce it. At six days the sensitivity had disappeared. There was no agglutination of the control cells in antiserum or of any of the cells in normal serum. This result demonstrates that hæmosensitization can take place in the blood stream of the living animal in spite of the presence of undiluted plasma, which is known to have a certain inhibitory effect on the reaction *in vitro*.

Leucocytes were used for demonstrating whether other types of cells could also fix hæmosensitins. In a typical experiment, a citrated suspension of guinea pig leucocytes was obtained from a peritoneal exudate after injection 16 hr. previously of 50 ml. Locke's solution. 68 per cent of the cells were polymorphonuclear. The exudate was divided into two portions, to one of which was added polysaccharide to a final concentration of 1 mgm./ml. Both portions were then incubated for 1 hr. at 37° C. and then washed; after resuspension, each was further divided into two parts, which were added respectively to suspensions of normal erythrocytes and of erythrocytes themselves sensitized with the polysaccharide. The resulting suspensions, which were made in normal guinea pig serum, consisted of approximately equal numbers of erythrocytes and white cells. Antiserum was added to a sample of each mixture to a final concentration of 1 per cent, and normal rabbit serum to a second sample. Microscopic examination after 3 hr. at room temperature showed that, in the tube containing leucocytes treated with polysaccharide, sensitized red cells and antiserum, 65 per cent of the leucocytes, comprising both polymorphonuclear and mononuclear cells, were in direct contact with erythrocytes. In the tube containing antiserum and sensitized erythrocytes but in which the leucocytes had not been treated with hæmosensitin, only 9 per cent of the latter were in contact with erythrocytes. In each of the other six tubes in the series, this figure was less than 15 per cent.

Similar experiments have been carried out with suspensions of lymphocytes obtained from lymph glands. For example, in one experiment, 55 per cent of the polysaccharide-treated lymphocytes were found to be incorporated in the clumps of sensitized erythrocytes in the presence of antiserum, whereas in the corresponding tube containing untreated lymphocytes the erythrocyte clumps were virtually free of lymphocytes, only 1 per cent of which were in contact with erythrocytes. Thus, when both leucocytes and erythrocytes are treated with hæmosensitin and are afterwards exposed together to the antibacterial serum, a specific adherence of leucocytes to erythrocytes occurs. This indicates that material of the same antigenic specificity has become fixed on to the surfaces of both types of cell.

Two main conclusions may be drawn from these studies. In the first place, it has been shown that hæmosensitization can take place *in vivo* when a high enough concentration of hæmosensitin is reached in the immediate environment of the cells. Secondly, the ability to fix these substances is not limited to erythrocytes, but is shared by leucocytes, and it seems probable that many other types of cell in the body may be capable of this activity.

This work was carried out in Paris during the tenure of an exchange scholarship of the Medical Research Council and the Centre National de la Recherche Scientifique.

## Cost of German Medical and Scientific Periodicals

Dr. W. Bonser and Miss Margaret P. Russell have discussed the prices of German medical and scientific periodicals in *Nature* of September 13, 1952, p. 446.

The prices of the periodicals published by the Springer Verlag are fixed in such a way that the number of subscriptions wholly, or at least approximately, covers the costs of production. It is only through subsequent orders that a profit is made. This method automatically leads to a reduction in price when the number of subscribers increases. Thus in July 1952, we announced reduced prices for 1953 for the following periodicals: *Zeitschrift für Physik*, *Zeitschrift fur analytische Chemie*, *Biochemische Zeitschrift* (by DM 10 per volume), and *Archiv für experimentelle Pathologie und Pharmakologie* (by DM 8 per volume), that is, some DM 30 less per annum for each of the four periodicals.

A comparison with the cost of periodicals from other countries, particularly from Anglo-Saxon countries, is misleading, for conditions there are quite different.

(1) The number of subscribers is much larger than that to German periodicals. For example, the number of subscribers to the *Zeitschrift für Krebsforschung* is 400, and to *Cancer* 4,000. Our experience is that a reduction in price would not essentially change this proportion. We publish many special periodicals demanding numerous illustrations of high standard, and appealing to only a few hundred subscribers.

(2) Especially in the United States and Great Britain, the periodicals often receive financial support either from scientific societies or universities, or from the Government or from the author himself. For example, in the *Physical Review* and *Journal of Chemical Physics*, the author or his institute has to contribute 15 dollars per page. For the *Journal of Neuropathology* the author is not reimbursed for his expenses nor does he receive free separate prints, but is asked to answer for part of the costs of production.

With reference to particular points made by Dr. Bonser and Miss Russell, we wish to make the following comments:

(1) *Annual cost.* Since 1933, foreign libraries have received price lists every year showing the maximum cost for the coming year.

(2) With the exception of one Swiss journal erroneously mentioned, the list supplied to us by Dr. Bonser and Miss Russell in which Springer periodicals are compared with periodicals of other German publishing houses contains only periodicals which are published—or at least printed—in the Eastern Zone of Germany, where the costs of production are at most one-half as high, not considering the difference in currency exchange.

(3) The tables of the detailed list which Dr. Bonser and Miss Russell were kind enough to let us have can scarcely be considered as a basis, in so far as (*a*) a comparison is made not of the prices per sheet but of the total prices without regard to number of pages and get-up (number and quality of illustrations); (*b*) devaluation of sterling is mentioned but not allowed for in the tables; (*c*) it was due to measures (now abandoned) taken by the German Government to promote export that, during 1935–45, selling prices abroad were 25 per cent lower than on the home market.

Springer periodicals are published at the expense and risk of the publishing house alone. Costs of production of West German publishing houses had risen in 1949 to two and a half times the pre-war level and are now three times as high. The prices per sheet of Springer periodicals, on the other hand, average only twice as high as before the War.

SPRINGER VERLAG

Neuenheimer Landstrasse 24,
Heidelberg.

We wish to make the following reply to some of the points in the above letter from the Springer Verlag. It quotes from the fuller version of our paper, necessarily condensed in *Nature*, but now widely circulated.

The primary fact that the cost of German, and especially of Springer's, periodicals is far in excess of that of other countries still holds. The reduction in their sales which is likely to result must prove detrimental, scientifically as well as financially, to German progress.

The Springer Verlag points out that its periodicals are completely its own financial venture. We have already suggested, in our fuller paper, that a solution to the problem might be a change-over of responsibility to the German societies concerned, as has been done for certain publications in Great Britain and the United States.

We should like to reply to the following comments on details.

(2) The Swiss journal (*Annales Pædiatrici*) was not "erroneously mentioned" but was intentionally included, since it is the continuation of the German journal *Jahrbuch für Kinderheilkunde*, both of which have the same publisher now in Basle but formerly (until the end of 1938) in Berlin.

(3*a*) We actually did compare two journals from the point of view mentioned, namely, the *British Journal of Experimental Pathology* and the *Archiv für experimentelle Pathologie*, to the great disadvantage of the Springer periodical; (3*b*) it was pointed out that devaluation of sterling amounted to 45 per cent for American and only 26 per cent for German periodicals—the figures presented in our table are the resultant prices paid by us.

We feel that our table of comparisons still stands as a summary of facts, and we still hope that some means of reducing the cost of these essential contributions to knowledge, so as to be comparable with those of other German firms, may be possible.

MARGARET P. RUSSELL

Medical School,
University of Birmingham.

# FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

## Monday, March 2

SOCIETY OF CHEMICAL INDUSTRY, LONDON SECTION (joint meeting with the INSTITUTE OF PETROLEUM, at the Institution of Electrical Engineers, Savoy Place, Victoria Embankment, London, W.C.2), at 10 a.m.—Symposium on "Production and Utilization of Petroleum Raw Materials in the U.K. Chemical Industry".

BRITISH SOCIETY FOR THE HISTORY OF SCIENCE, PHILOSOPHY OF SCIENCE GROUP (in the Joint Staff Common Room, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Annual General Meeting.

SOCIETY OF ENGINEERS (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Mr. C. L. Boucher and Mr. D. Bagley: "Developments in the Recovery of By-Products from Coke Oven Gases".

UNIVERSITY OF LONDON (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. A. Unsöld: "Some Recent Progress in Astrophysics".* (Further Lecture on March 4.)

UNIVERSITY OF LONDON (at King's College, Strand, London, W.C.2), at 5.30 p.m.—Prof. H. C. Longuet-Higgins: "Matter". (Inaugural Lecture in the Chair of Theoretical Physics.)*

## Tuesday, March 3

UNIVERSITY OF LONDON (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 1.15 p.m.—Mr. A. R. Jonckheere: "Recent Experiments in the Psychology of Learning".*

SOCIETY OF PUBLIC ANALYSTS AND OTHER ANALYTICAL CHEMISTS, PHYSICAL METHODS GROUP (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 6.30 p.m.—Absorptiometry Meeting.

SHEFFIELD METALLURGICAL ASSOCIATION (in the Grand Hotel, Sheffield), at 7 p.m.—Mr. D. R. O. Thomas: "Technological Education in relation to the Iron and Steel Industry".

SOCIETY OF COSMETIC CHEMISTS OF GREAT BRITAIN (at the British Colour Council, 13 Portman Square, London, W.1), at 7 p.m.—Mr. J. K. Barraclough: "Dyes".*

## Wednesday, March 4

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W.C.2), at 2.30 p.m.—Dr. C. B. Frisby: "The Assessment of Suitability for Employment".

## Thursday, March 5

ROYAL SOCIETY (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Sir Harold Hartley, F.R.S.: "Sir Humphry Davy, Bt., P.R.S." (Wilkins Lecture).

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 5.15 p.m.—Sir Lawrence Bragg, F.R.S.: "X-Ray Optics". (Further Lectures on March 12, 19 and 26.)

BRITISH INSTITUTION OF RADIO ENGINEERS, SCOTTISH SECTION (in the Lecture Theatre, The University, Glasgow).—Dr. J. M. Reid: "Electronics in Nuclear Research".

## Friday, March 6

INSTITUTION OF MECHANICAL ENGINEERS (joint meeting with the Steam Group, at Storey's Gate, St. James's Park, London, S.W.1), at 10.30 a.m.—Series of Papers from the Parsons and Marine Engineering Turbine Research and Development Association dealing with Steam Turbine Research and Development work carried out at their Research Station.

SOCIETY OF PUBLIC ANALYSTS AND OTHER ANALYTICAL CHEMISTS (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 2.45 p.m.—Annual General Meeting; at 3.15 p.m.—Dr. J. R. Nicholls: Presidential Address.

ROYAL INSTITUTE OF PHILOSOPHY (at University Hall, 14 Gordon Square, London, W.C.1), at 5.30 p.m.—Mr. Meyrick H. Carré: "Poetry and Philosophy".

UNIVERSITY OF LONDON (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 5.30 p.m.—Prof. G. F. Marrian, F.R.S.: "Some Aspects of the Metabolism of the Steroid Hormones".*

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 9 p.m.—Prof. R. V. Jones: "The Pressure of Radiation".

## Saturday, March 7

NUTRITION SOCIETY (at King's College of Household and Social Science, Campden Hill Road, London, W.8), at 10.15 a.m.—Symposium on "Education in Nutrition in the United Kingdom".

LONDON COUNTY COUNCIL (at the Horniman Museum, London Road, Forest Hill, London, S.E.23), at 3.30 p.m.—Dr. John Layard: "The Journey of the Dead in Malekula, New Hebrides".*

JOINT BIOLOGY COMMITTEE and the ASSOCIATION OF AGRICULTURE (at University College, Gower Street, London, W.C.1).—Conference on "Plant and Animal Breeding".

# APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

LECTURER IN AGRICULTURAL CHEMISTRY—The Secretary, Edinburgh and East of Scotland College of Agriculture, 13 George Square, Edinburgh (March 7).

SCIENTIFIC OFFICERS (Grade 3) and SCIENTIFIC OFFICERS (Grade 1) for research and development in (a) radio transmission and reception at high and ultra-high frequencies, (b) modulation methods and terminal equipment, and theory connected therewith, (c) electronic and electromechanical equipment for computing and recording, and EXPERIMENTAL OFFICERS (Grade 3) and EXPERIMENTAL OFFICERS (Grade 1) for research or development associated with (a) radio transmission and reception at high and ultra-high frequencies, (b) modulation methods and terminal equipment, (c) electronic and electro-mechanical equipment for computing and recording; at the Electronic Research Laboratory, Salisbury, Australia—The Senior Representative, Department of Supply, Canberra House, 87 Jermyn Street, London, S.W.1 (March 7).

BIOCHEMIST at the Southport General Infirmary—The Secretary, Southport and District Hospital Management Committee, Promenade Hospital, Southport (March 9).

DEMONSTRATOR or ASSISTANT LECTURER IN THE DEPARTMENT OF PHYSICS—The Secretary, Bedford College, Regent's Park, London, N.W.1 (March 9).

DEPUTY DIRECTOR OF RESEARCH—The Director of Research, British Leather Manufacturers' Research Association, Milton Park, Egham (March 9).

LECTURER IN THE DEPARTMENT OF MINING AND GEOLOGY—The Principal, Wigan and District Mining and Technical College, Wigan (March 9).

ASSISTANT LECTURER IN ENGINEERING (with qualifications in civil engineering, with special interests in structures or hydraulics)—The Registrar, The University, Manchester 13 (March 11).

HEAD OF THE DEPARTMENT OF PHYSICS, Makerere College (University College of East Africa)—The Secretary, Inter-University Council for Higher Education in the Colonies, 1 Gordon Square, London, W.C.1 (March 12).

LECTURER IN MEDICAL STATISTICS—The Registrar, The University, Manchester 13 (March 12).

CHEMICAL ENGINEERS, MECHANICAL ENGINEERS, METALLURGISTS, THEORETICAL PHYSICISTS, CHEMISTS, and PHYSICISTS (Senior Principal Research Officer, Principal Research Officer, Senior Research Officer and Research Officer grades) in the Commonwealth Scientific and Industrial Research Organization, for research in the field of development of atomic energy as a source of industrial power—The Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2, quoting No. 4157 (March 14).

RESEARCH WORKERS (2, one with zoological, the other with botanical training) to establish a unit for the study of the ecology of polluted rivers and streams—The Director, Freshwater Biological Association, The Ferry House, Far Sawrey, Ambleside, Westmorland (March 14).

ANALYST (with sound experience in the analyses of fertilizers, soils and other agricultural materials) IN THE DEPARTMENT OF CHEMISTRY—The Registrar, Wye College, Wye, Ashford, Kent (March 16).

BOTANIST (Assistant Lecturer grade) in the Marine Biology Station—The Secretary and Registrar, University College of North Wales, Bangor (March 17).

ASSISTANT LECTURER IN MATHEMATICS (with special qualifications in applied mathematics)—The Registrar, The University, Manchester 13 (March 18).

HEAD OF THE DEPARTMENT OF MECHANICAL ENGINEERING—The Registrar, College of Technology, Suffolk Street, Birmingham 1 (March 20).

HEAD OF THE DEPARTMENT OF MATHEMATICS, and a LECTURER or ASSISTANT LECTURER IN CHEMISTRY (preferably in physical inorganic chemistry), at Makerere College (University College of East Africa)—The Secretary, Inter-University Council for Higher Education in the Colonies, 1 Gordon Square, London, W.C.1 (March 21).

AGRICULTURAL OFFICER (with degree in agriculture or equivalent, with at least two years postgraduate experience) in Sarawak, for extension and investigational work in a district under fairly strenuous conditions—The Director of Recruitment, Colonial Office, Great Smith Street, London, S.W.1, quoting CDE.63/24/02.

AGRICULTURIST (with degree in agriculture or horticulture and, preferably, with knowledge of commercial date cultivation) in the Somaliland Protectorate, to take charge of experimental scheme for date cultivation with a view to its eventual expansion—The Director of Recruitment, Colonial Office, Great Smith Street, London, S.W.1, quoting CSC 63/5/01.

CHEMIST (with good honours degree in chemistry or agricultural chemistry, and postgraduate research experience, preferably in soil science) IN THE DEPARTMENT OF SCIENCE AND AGRICULTURE, Barbados, for investigational and advisory work on soils, soil survey and analysis, manurial trials, etc.—The Director of Recruitment, Colonial Office, Great Smith Street, London, S.W.1, quoting CDE 83/28/01.

CIVIL ENGINEERS in various branches of the Public Works Department in Nigeria, for general civil engineering, irrigation projects, rural and urban water supplies, road development, etc.—The Director of Recruitment, Colonial Office, Great Smith Street, London, S.W.1, quoting CDE.112/14/03.

METEOROLOGIST (with a first- or second-class honours degree in mathematics or physics) in Nigeria, for meteorological forecasting, research, climatology and administrative duties involved in the organization of the Service—The Director of Recruitment, Colonial Office, Great Smith Street, London, S.W.1, quoting CDE.57/14/01.

SCIENCE GRADUATE (preferably with some research, production, or information experience) as scientific assistant in the Information Department—The Information Officer, British Scientific Instrument Research Association, Sira, Southill, Elmstead Woods, Chislehurst, Kent.

SENIOR LECTURER IN CHEMICAL ENGINEERING—The Principal, West Ham College of Technology, Romford Road, London, E.15.

TEACHING AND RESEARCH ASSISTANTS (part-time) IN THE DEPARTMENT OF PHYSICS—Dr. A. B. McLay, Chairman of the Physics Department, Hamilton College, McMaster University, Hamilton, Ont., Canada.

ZOOLOGISTS (with good honours degree in zoology, and at least two years postgraduate experience) in the East African Tsetse and Trypanosomiasis Research and Reclamation Organization, for research into distribution and behaviour of tsetse fly and their ecological background—The Director of Recruitment, Colonial Office, Great Smith Street, London, S.W.1, quoting CDE.77/88/01.

# OVERSEAS DEVELOPMENT AND MAN-POWER PROBLEMS

THE Volta River aluminium scheme[*] set forth in a White Paper issued in November 1952 is of exceptional interest, quite apart from its possible contribution to the supply to the industry of the United Kingdom of aluminium from within the 'sterling area' at competitive prices. Under the scheme the United Kingdom Government, the Gold Coast Government and the producers would develop the resources of water-power and bauxite in the Gold Coast to yield ultimately 210,000 tons of aluminium annually. An initial capital expenditure of about £100 million would be required, rising eventually to £144 million, and in the White Paper the British Government states that it believes the scheme to be soundly conceived. The magnitude of the undertaking is such, however, that it considers that the scheme should not be embarked upon without every practicable assurance that it can be carried through to a successful conclusion. The British Government proposes, therefore, with the agreement of the Gold Coast Government and the aluminium producers, to set up at once a Preparatory Commission to follow up the work already done and to examine in greater detail the chief problems which would have to be overcome. This Commission would be instructed to report with all practicable speed so that final decisions could be taken as soon as possible. The cost of this Commission, of which Commander R. G. A. Jackson will be in charge (see *Nature*, February 21, p. 330), will be shared in the first place between the Governments of the United Kingdom and of the Gold Coast.

The wider interest of the scheme is derived, however, from its bearing on Colonial development and welfare. In commending the scheme, the White Paper points out that as one result the Gold Coast would be enabled to develop further its mineral wealth and to create a new source of power of great potential benefit to its future social and economic progress; and a reason given for favouring participation in the scheme by the British Government is that it would further the Government's policy of encouraging the development of the resources of the Commonwealth as well as contributing to the raw material needs of the United Kingdom. This applies particularly to the hydro-electric aspect of the scheme. The possibility of developing hydro-electric power from the Volta River, which is the principal river of the Gold Coast, with a total length of some 1,000 miles and a drainage area of about 150,000 square miles, of which roughly 40 per cent lies within Gold Coast territory, has been considered at various times during the past three decades. Proposals for the construction of a dam at Ajena in the Akwapim Hills for generating power for the production of aluminium were considered by the Gold Coast Government in 1924; but a detailed survey started in 1938 by Mr. Duncan Rose was interrupted by the Second World War. Six years later, West African Aluminium, Ltd., was formed with Mr. Rose as chairman to carry the scheme further, while in January 1951 a joint mission of Aluminium, Ltd., of Canada and the British Aluminium Co., after further detailed study, reported that the scheme prepared by West African Aluminium, Ltd., was a sound engineering proposition and could produce aluminium at an economic cost.

---

[*] Volta River Aluminium Scheme. (Cmd. 8702.) Pp. ii+22. (London: H.M. Stationery Office, 1952.) 9d. net.

Meanwhile, the Gold Coast Government, which had long recognized the possibilities of the Volta River, but which also realized that the heavy capital expenditure required would not be justified unless there were adequate industrial outlets for the large quantities of power produced, decided that the development of the Volta River basin should be viewed as a whole and in relation to the total economy of the Gold Coast, rather than merely in relation to the most important immediately visible outlet for power. In October 1949 it engaged Sir William Halcrow and Partners to undertake a survey of all aspects of the Volta River development, including not only hydro-electric power but also irrigation and drainage of lands in or near the catchment of the river, navigation on the river, transport and port facilities. The British Government itself both encouraged the examination of the practicability of aluminium production in the area by the joint mission of Aluminium, Ltd., and the British Aluminium Co. already noted, and provided in the year ended March 31, 1950, £15,000 for a scheme made under the Colonial Development and Welfare Acts for a comprehensive survey of all aspects of the scheme to determine the potential value of the river. During 1951–52 a further £19,000 was provided for a scheme for an aerial survey of part of the Volta River basin in connexion with the projected hydro-electric scheme.

Sir William Halcrow and Partners submitted a preliminary report dated July 25, 1950, and in a final report on August 15, 1951, set out a scheme for the development of the Volta basin. So far as it related to aluminium production, this report was the basis for the subsequent exploratory discussions between representatives of the United Kingdom and Gold Coast Governments, of Aluminium, Ltd., and of the British Aluminium Co. in October and November 1951 and in May 1952 in London, and in June 1952 in Accra. The discussions considered the conditions under which the two Governments and the aluminium companies might jointly participate in a scheme for aluminium production in the Gold Coast, and the scheme proposed in the White Paper is the outcome of these discussions.

The scheme now proposed envisages the construction of a dam and power-station at Ajena in the gorge through the Akwapim Hills and would create a lake with an area of some 2,000 square miles. After allowing for other users in the Gold Coast, the power available from the hydro-electric installation would suffice for an aluminium smelter, operating on bauxite drawn from reserves within the Gold Coast, and sited at Kpong, twelve miles from the dam, to produce 210,000 tons of aluminium a year. The smelter and bauxite mines would be managed by private enterprise through a smelter company financed mainly by the aluminium companies with some support from the Gold Coast Government, though the scheme contemplates that up to half the capital required to expand the capacity of the smelter from its initial 80,000 to 120,000 tons a year may be provided by the United Kingdom Government.

The United Kingdom and Gold Coast Governments would be jointly responsible for financing the hydro-electric undertaking as a whole, the ultimate cost of which is estimated at £54 million. Apart from a minimum of £8 million contributed by the Gold Coast Government, which would be solely responsible for facilities for the distribution of power to other users besides the smelter, this would be borne by the United Kingdom Government, whose maximum expenditure is visualized at £56·8 million. The Gold Coast Government would be responsible for providing the £26 million required for port, rail, road facilities and other public works. Apart from that fraction of capital for the smelter provided later by private investors, the remainder of the £144 million for the whole scheme would be provided by the Gold Coast Government or the aluminium companies.

As already indicated, the scheme contemplates extensive public works. Establishment of an aluminium industry of this magnitude would necessitate construction of a new port conveniently situated to serve its needs. Accra has already reached the limit of its capacity and is unsuitable for further development as a port. Takoradi, the only major port in the Gold Coast, has recently been extended, but Sir William Halcrow and Partners recommended that a new port to serve both the general and the aluminium needs should be constructed at Tema, about twenty miles east of Accra. After obtaining a second opinion the Gold Coast Government has already decided to construct a new port at Tema, whether or not the whole scheme is undertaken, and preliminary work is in hand.

Besides this, a considerable development of communications would be required, particularly of railways, linking the new port at Tema with both Accra and Kpong and providing for movement of the bauxite by rail. Existing roads would need improvement and new roads would have to be built. It is proposed accordingly that the Gold Coast Government should set up a Volta River Authority, which would be responsible for co-ordinating all planning and construction work arising out of the Volta River scheme, including the building of the dam and power station, the aluminium smelter and alumina works, port and railway facilities, roads and townships. On completion of the construction work, the Volta Electricity Board would be set up to assume responsibility for the management of the power undertaking and also for the installation of additional generating units, transmissions and extension to the original works.

It is this aspect of the scheme which strikes the imagination. The analogy with the Tennessee Valley Authority is unmistakable, and from the caution with which both the Gold Coast Government and that of the United Kingdom are proceeding it is clear that in the minds of all concerned the development and welfare of the people of the Gold Coast and not the exploitation of an important mineral resource are the dominant considerations. The appointment of a preparatory commission to examine in greater detail the chief problems which would have to be overcome shows that the lessons of earlier failures, such as the groundnuts scheme in East Africa and the poultry scheme in Gambia, have been learnt; and the Gold Coast Government, no doubt with the warning of Abadan in mind, is no less anxious to avoid even the appearance of an infringement of national independence.

If the scheme proves practicable and the technical problems can be surmounted, the financial proposals appear to be reasonable and flexible enough to accommodate political changes if they are made in good faith. To execute the scheme, moreover, demands not merely the supply of capital by Great Britain and a further drain on the country's limited supplies of technical experts, but also co-operation over a period of years between such experts and the peoples of the Gold Coast. Under the proposed Volta River Authority, the people of the Gold Coast should receive a training in responsible local administration which may itself materially smooth the path for the advance of the Gold Coast towards Dominion status. The very conditions essential for the technical execution of the scheme involve a spirit of co-operation and mutual understanding and a training in democratic methods calculated to engender the atmosphere and the goodwill which are the best safeguards against dangers from prejudice, misunderstanding and racial sentiment a generation or more hence.

The importance of this factor was stressed by Lord Rennell in a debate in the House of Lords on the Gold Coast last July, and it affects equally the Technical Assistance programme of the United Nations. Lord Rennell inquired specifically regarding the relationship between the new nationalist governments which are being set up and European capital and investors, on one hand, and their own European staff, on the other. It is unlikely, he pointed out, that either capital or technologists would be attracted to the Gold Coast from Britain and the United States for the Volta River scheme unless the sponsors of the scheme have confidence in the direction of constitutional development there. The Parliamentary Under-Secretary of State for the Colonies, the Earl of Munster, in replying to the debate, was able to supply evidence that Dr. K. Nkrumah and the Ministers of the young Gold Coast Government recognize the need both to maintain the goodwill of overseas investors and to retain the services of their European staff, and are dealing with some success with the difficulties caused by the anti-European feeling which brought them to power.

Nevertheless, as was emphasized in a recent broadsheet from Political and Economic Planning (see *Nature*, 170, 679; 1952), the supply and quality of the technical experts remain the critical factors, and in this respect the Volta River scheme is no exception. Such questions as the numbers of technical experts required and the conditions of service to be offered to them are among the most important which the Preparatory Commission will have to consider. Failure to handle them in a way which will attract men of the requisite calibre would jeopardize the execution of the scheme no matter how excellent its technical merits. Moreover, although the situation in regard to scientific and technical man-power for such projects may be easier than in November 1949, when Dr. W. F. P. McLintock expressed the view before the Parliamentary and Scientific Committee that Great Britain's man-power resources in this field were already strained to the utmost (cf. *Nature*, 165, 251; 1950), it must not be assumed that no special efforts will be required to find the necessary staff or that the effect on the man-power situation can be disregarded. So late as May 1952, Lord Reading expressed the view that our own man-power was still severely strained, and it would seem that a report from the sub-committee of Lord Hankey's Technical Personnel Committee which is dealing with overseas requirements is overdue.

The last report on "Colonial Research" and the survey "The Colonial Territories 1951–52" both indicated some improvement in the staff position in the Colonial Service. Apart from this, up to September 30, 1952, Great Britain had offered 65 technical experts against a total of 136 requested under the technical co-operation scheme of the Colombo Plan. It has also offered 416 of the 613 training places requested, as well as a further 300 places against which nominations have yet to be made by Colombo Plan countries. These requests are chiefly for India, Pakistan and Ceylon: the needs of Burma and Indonesia have as yet scarcely been charted.

Thus the need for technical help in southern Asia is likely to exceed supply for a long time to come. Even, therefore, if the strain on the world's scientific and technical man-power is diminished by the new method of technical assistance for backward countries adopted by the United Nations, under which collective advice is given by the developed countries, it may still be necessary for the execution of such schemes to contemplate the recruitment of experts not merely from Great Britain but also from elsewhere. The United Kingdom Government itself has suggested that, in view of the difficulty of finding suitable experts for specific projects, requests for the services of British consultant firms and technical consultants could be considered as part of the Colombo Plan. Such requests have already been received from India, Pakistan and Ceylon and are being negotiated.

However successful the fuller use of scientists or technologists as consultants may prove in meeting the situation, more also in the way of international co-operation may well be required. The Parliamentary and Scientific Committee when discussing the general problem had Anglo-American co-operation specially in mind; but there is also a considerable reservoir on the European continent which could be tapped. Switzerland, Denmark, Austria and Western Germany might well contribute appreciably to the numbers of engineers, scientists and medical men required for such schemes as the Volta River project under appropriate conditions, and there might be advantages in recruiting overseas staff from different countries, provided the essential conditions were fulfilled.

Those conditions, upon which the successful execution of even the soundest development scheme depends, are not purely technical on either side. Good faith and goodwill, vision and understanding as well as technical and scientific competence are required of the expert. Good faith and goodwill and imagination must no less be shown by the responsible government of the territory concerned. On that government rests, further, the responsibility for establishing the conditions which will both attract the capital required for development and the men to carry it out. Above all, having attracted the experts of the necessary quality, it must provide the conditions of service which will enlist their loyalty in the imaginative service not merely of one territory or people but, through that people and territory, of mankind.

---

## PHYSICS OF THE EARTH

### The Earth

Its Origin, History and Physical Constitution. By Dr. Harold Jeffreys. Third edition. Pp. xiv+392+10 plates. (Cambridge: At the University Press, 1952.) 70s. net.

A COMPARISON between the third edition of Jeffreys's book, "The Earth", long awaited by geophysicists and geologists, and the second edition (1929) brings out the developments in geophysics in recent years. In some geophysical fields the ideas of twenty-five years ago have been confirmed and expanded; in others they have had to be abandoned and frequently replaced by a variety of hypotheses conflicting with each other. In this latter group belong the hypotheses on the origin of the solar system and the earth. The chapters previously devoted to these subjects have been omitted in the new edition, which begins with fundamental equations of elastic and non-elastic motions. Unfortunately, experimental research on creep and plastic flow is still in its early stages, whereas the theoretical treatment of such processes and of fracture in the earth is very complicated except with very special assumptions. A short discussion of rock types and minerals concludes the first chapter.

Chapter 2, the theory of elastic waves, forms the basis for Chapter 3, on observational seismology, which opens with a few remarks on seismographs (pp. 64–65). In the discussion of records of nearby earthquakes, Jeffreys is handicapped by the fact that the European material on which he relies to a great extent is inferior to that available in several other regions of major activity. Data from the latter show more 'disturbing features' than Jeffreys mentions and leave little doubt that our ideas concerning the outer layers of the earth, including the so-called granitic layer in the continents, are even less certain than indicated by him. This chapter also includes discussions of travel times, of body waves and of surface waves, with examples of their use in determining the structure of the earth. In the concluding pages (119–120) of Chapter 3 a few hypotheses on microseisms are mentioned with some details concerning the ideas of Deacon, Longuet-Higgins and Miche concerning the process in which energy is transmitted from ocean waves to the bottom. Chapters 1 to 3, seismology in a wide sense, cover the first third of the book.

In Chapter 4 the figure and density of the earth are discussed. Here, as in other parts of the book, much is based on Jeffreys's own research. Some of the always-changing hypotheses concerning the outer and inner core—iron or high-pressure form of olivine or other material—are treated. Chapter 5 includes a discussion of the gravity field of the earth and of isostasy. Chapter 6 begins with theoretical problems connected with static loads. Solutions for elastic and non-elastic conditions are considered, and gravity anomalies are discussed. Jeffreys concludes that stress differences of at least $1{\cdot}5 \times 10^7$ dynes/cm.$^2$ exist within the outermost 50 km. of the earth and that differences of the order of $2 \times 10^8$ may exist between depths of 50 to 600 km. without producing fracture.

Chapter 7 contains details of the theory of variations of latitude and the bodily tides of the earth and a discussion of the associated constants, and the succeeding chapter is devoted to tidal friction of the earth and other planets with some remarks on the resonance theory of the origin of the moon. Thus Chapters 4–8 (pp. 121–248) mainly cover geodetic problems.

The last third of the book begins with methods used to determine the age of the earth (Chapter 9). "There is general consistency with an age in the neighbourhood of 2000–3000 million years." The question as to whether the earth started as a hot or cool body enters here, as well as the problem of the thermal history of the earth (Chapter 10, pp. 271–302). If the earth was originally liquid and cooling, the solution of the problem as to where solidification started depends on the relationship between melting-point gradient and adiabatic gradient. Jeffreys believes that the former exceeds the latter at all depths, and that the earth's shell solidified from the bottom upwards. During solidification materials separated; some details are discussed. The problem of the heat developed in radioactive processes leads to a more detailed discussion of the radioactivity of rocks at present and in the past, and its effect on the assumed cooling of the earth. In the mantle, the depth where the temperature approaches the melting point most closely is most likely at the bottom of the 'intermediate layer' in the continents. Recent findings of a relatively large heat flow in the bottom of the Pacific remain unexplained. Jeffreys discusses here once more the composition of the core in the light of recent ideas about atomic structure, as well as Bullen's hypothesis that in the deeper parts of the earth the bulk modulus is mainly a function of pressure.

Chapter 11 is devoted to the origin of the earth's surface features and to geotectonic hypotheses such as the contraction theory (which Jeffreys supports) and convection theories. Also included are remarks on changes in the earth's rotation, elastic instability, the origin of the continents and ocean basins, and on volcanism. In Chapter 12, Jeffreys discusses various phenomena such as after-shocks, movements of the earth's axis, continental drift, surface features of the moon and growth of continents. On pp. 357–371 he gives a mathematical background for some of the problems. The book concludes with some "Notes" on recent findings, and a subject index.

Unfortunately no geophysicist can now be familiar with the progress made in all fields of geophysics nor study in detail the whole literature. Thus, in this new edition little or no space is devoted to problems concerning the earth's magnetism and to the results of Benioff or of M. Ewing and his group. Some geophysicists, geologists or geochemists will find that the discussion of one of their special problems is not quite up to date. But there can be no doubt that a study of the new edition of this classical work is essential for all those who are interested in the development and structure of the earth or in the properties of its interior. B. GUTENBERG

## TEXT-BOOK ON PLANT PROTECTION

Elements of Plant Protection

By Dr. Louis L. Pyenson. (Wiley Farm Series.) Pp. x+538. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1951.) 40*s*. net.

DR. L. L. PYENSON has produced a comprehensive elementary text-book of plant protection. All types of plant pests are dealt with—animals, both invertebrate and vertebrate, fungus and virus diseases, and weeds. In addition, there is a section dealing with equipment required for combating plant pests.

Throughout the book the author's aim has been to emphasize the general principles underlying all plant protection rather than to specify each and every control method. He has therefore divided the book into a number of sections, each dealing with a particular group of plant pests, and he has introduced each section by one or more chapters describing simply the biology of the group. These introductory chapters are perhaps unnecessarily elementary for the majority of students; but they do emphasize that there must be a sound knowledge of the biology of a given pest before a suitable method for its control can be selected. Unfortunately, some of the information they contain has been over-generalized to the point of inaccuracy; the description of the characteristics of the insect nervous system (p. 29) is an example. But the author's wide experience has enabled him to present a balanced account of plant protection and to assess all control methods strictly at their true value.

Many features of the book are excellent, especially the diagrams detailing the life-histories of a large number of plant pests and the tables setting out such diverse things as the diets of various birds, the purposes and limitations of various insecticides, pests and plant diseases associated with certain weeds, and the compatibility of common spray materials, to mention only a few.

The information on the control of insect pests is sound, and, as a result of the approach by way of general principles, biological control is given fair consideration. Control of fungus and virus diseases of plants and weed control are also well described, while the section on application equipment is excellent. Of course, a good deal of the more specialized information given applies only in the United States. Also, the colloquial names of the species mentioned in the text are American and often not current in Britain. The latter difficulty is not very serious, since the scientific name is nearly always quoted in addition to the colloquial one. Each chapter is followed by a list of questions, which are well chosen and stimulate a critical and reasoned approach to the subject. The somewhat condensed style of writing presumably results from including so much information in a book of such modest size. This conciseness, however, while making the book less readable, has not interfered with its lucidity. The book is well produced and the printing legible; but the pages present a somewhat untidy appearance due to the method of word-spacing used. P. E. BURT

## WAVE MECHANICS FOR BEGINNERS

Elements of Wave Mechanics

By Prof. N. F. Mott. Pp. ix+156. (Cambridge: At the University Press, 1952.) 21*s*. net.

ALTHOUGH the principles of wave mechanics have been well established for almost a quarter of a century, there is, at present, no unanimity of view regarding the most satisfactory way of presenting the subject to the beginner. A glance at the introductory chapters of the numerous books on wave mechanics, or quantum mechanics, published in recent years shows the extent to which authors differ in their method of introducing the new principles. Some favour an axiomatic approach and base the theory on a few precisely stated postulates the justification of which is simply that they lead to a successful theory. Others prefer a more historical approach in which the Correspondence Principle of Bohr and the analogies with geometrical and wave optics are stressed.

In this new book, which is intended to replace the older "An Outline of Wave Mechanics", Prof. N. F. Mott presents the theory as a logical development from what are now well-established experimental data. He writes: "The theory will be based on a single experimental fact, the diffraction of electron beams". There are undeniable advantages in this approach to the subject, and it is no objection to the method that the theory was, in fact, well established before these particular experiments were made. With the skill of an experienced teacher, Prof. Mott leads the student on, from the wave equations of classical physics to the fundamental Schrödinger equation, with a minimum of discomfort and a considerable sense of continuity. The well-known stumbling blocks, such as the complex character of the wave function and the linearity in the time of the time-dependent Schrödinger equation, are met and most skilfully disposed of, and, by a series of well-chosen examples, the principal features of wave mechanics are brought to light.

For a book of this size a surprisingly large field of physics is covered. Apart from the more usual topics, such matters as the excitation of an atom by a passing proton or $\alpha$-particle are dealt with; there is a section on the theory of solids, and another on molecular structure; a few words are devoted to the relativistic wave equation and the positron; and the essentials of the theory of $\alpha$- and $\beta$-decay of nuclei are made clear. A feature of the book which will commend it to both students and teachers is the inclusion of a number of well-chosen exercises.

The author says in the preface that this book was written for students of experimental physics and to serve as an introduction to more advanced books for those who intend to specialize in this subject, and to these categories of students it can be unreservedly recommended. If those who afterwards study the more advanced text-books should be surprised at the difficulties they encounter, that will be due, not to any lack of rigour in their introduction to the subject, but to the skill with which they have been led along the smoothest paths at the beginning of their journey.

## SECOND BERKELEY SYMPOSIUM ON STATISTICS

### Proceedings of the Second Berkeley Symposium on Mathematical Statistics and Probability

Held at the Statistical Laboratory, Department of Mathematics, University of California, July 31–August 12, 1950. Edited by Jerzy Neyman. Pp. xi+666. (Berkeley and Los Angeles: University of California Press; London: Cambridge University Press, 1951.) 11 dollars.

A collection of papers presented at an international conference is apt to be disappointing. The proceedings take so long to appear in volume form that an author with something new to say is apt to publish it elsewhere for fear of anticipation. It has also to be admitted that some contributors have nothing much to say but think that the occasion is too good to let pass without sharing the limelight. In consequence, the final records of a conference tend to become monuments of past endeavour, with the magnificent façade of a mausoleum and about as much vitality as its contents.

But there are exceptions, and the Second Berkeley Symposium is among them. There are papers in this collection which will long be consulted as major contributions to mathematical statistics. Prof. J. Neyman is to be congratulated on the standard maintained by the contributors. The First Symposium was good, but this is even better, and if Prof. Neyman can continue at this level the Berkeley Symposia will take a high place among the statistical literature of the world.

There are forty-six papers in the collection: thirteen on mathematical statistics, fourteen on probability, five on astronomy, two on biometry, three on econometrics, five on physics, two on traffic engineering and two on wave analysis. The contributors to the first symposium were all United States citizens, but this collection contains some very distinguished foreign names—Cramér, de Finetti, Paul Lévy, Lindblad and Kampé de Fériet. There is, alas, no member of the British Commonwealth among them, but perhaps Prof. Neyman will remove this serious drawback in the third symposium which he hopes to organize.

Of the group on mathematical statistics, Wald's paper on asymptotic minimax solutions of point-estimation problems and Hoeffding's on optimum non-parametric tests, though written in abstract style, are well worth the trouble of mastering, a remark one cannot always make of papers in this subject. Hotelling, writing on a generalization of the $T$-test, shows how a difficult subject can be made lucid and readable. Blackwell's paper on the "Comparison of Experiments", following work by Bohnenblust, Shapley and Sherman, will be of general interest. An experiment $\alpha$ is said to be more informative than an experiment $\beta$ if, for every possible risk function, any risk attainable with $\beta$ is also attainable with $\alpha$. On this basis one can develop a kind of logic of experiment and set up criteria for the choice of methods leading to results which are by no means intuitively obvious.

The group of papers on probability are mainly written around the theme of dynamic probabilities: Paul Lévy on Wiener's random function, Kac on some connexions between probability theory and differential and integral equations, Feller on diffusion processes in genetics (a very readable little paper), several papers on random walks and ergodic theorems, and one by Doob on "Continuous Parameter Martingales"—a title which, rightly handled, could have added much to the gaiety of the proceedings.

I am not competent to express an opinion on the merits of the papers on astronomy and physics, but the papers by Lindblad on the dynamics of stellar systems, by Struve on stellar evolution considered statistically, and by Elizabeth Scott on the distribution of the elements of spectroscopic binaries, offer some interesting new statistical problems. The group on physics (Feynman on the concept of probability in quantum mechanics, Lewis on statistical questions in meson theory, and Lenzen on the philosophical problems of the statistical interpretation of quantum mechanics) indicate the advent of a useful *rapprochement* between statistics as generally studied and the specialized statistics of physical systems.

The two papers in the biometry section are somewhat misleadingly placed, for both raise questions of general interest. Cochran writes on improvement by means of selection, an important but neglected topic. Berkson, who is building up a reputation as the *enfant terrible* of the biometric world, shows by experiment and example that minimum chi-squared can be better than maximum likelihood in certain cases, a result which will make many of us think again about certain problems in statistical estimation.

In the econometrics section, Kuhn and Tucker write on non-linear programming, Marschak on "Why should Statisticians and Businessmen Maximize Moral Expectation?" (nobody claims that they do, but it is an interesting problem in decision-theory to ascertain why they should), and Arrow on classical welfare economics. Papers in the traffic engineering section on the distribution of vehicle speeds and travel times are significant contributions to congestion problems; and to conclude there are two interesting papers on the analysis of ocean waves by the correlogram. It is tragic to have to record that the author of the last paper in the book, H. R. Seiwell, like the author of the first, Abraham Wald, lost his life in an accident since the symposium was held.

A mere list of these papers indicates the enormous range of statistical methods at the present time. A glance through them will show what demands many of the subjects make on mathematical expertise, experimental skill and computational patience. A statistician is torn between pleasure at the extensive use made of his methods and regret at his inability to keep up with so many different developments. One of the most useful features of a collection like this—some of the papers being in the nature of reviews of current work—is that it enables one to see the main currents and to form a broad picture of what is going on. It only remains to say that the book is handsomely produced. The price may put it beyond the reach of the student, but all statistical libraries should possess it.

M. G. Kendall

# INSTRUMENTATION OF NUCLEAR REACTORS

AT a general meeting of the Institution of Electrical Engineers, held in the Institution's Lecture Theatre on January 8, a symposium of papers on the instrumentation of nuclear reactors was organized, at which about five hundred members and visitors attended, including guests from nuclear energy projects in France, Holland, Sweden, Norway and Italy. Colonel B. H. Leeson, president of the Institution, took the chair and introduced Sir John Cockcroft, whose lecture on "Nuclear Reactors and their Applications" provided a general background for the three specialized papers which followed.

Sir John began by describing the fission process, in which interaction between a neutron and a uranium atom may result in absorption of the former followed by fission of the latter, accompanied by the liberation of further neutrons and the release of energy. The probability of occurrence of this reaction depends upon which isotope of uranium is concerned, and upon the energy of the incident neutron. A system designed to enhance this probability is known as a nuclear reactor, and a classification into three main types is possible: these are known as fast, intermediate and thermal reactors, according to the energy-level at which it is intended that the incident neutron will cause fission. The critical state of a nuclear reactor occurs when, out of the neutrons released in an average fission, one survives all the processes leading to neutron waste, and initiates a further fission. If, however, more than one survives, a cumulatively increasing or divergent reaction results. If the number surviving is smaller than unity, the reaction diminishes until the fissions occur at a rate proportional to their rate of spontaneous occurrence in an isolated sample of uranium. The number of survivors thus defined is known as the reproduction factor, denoted by the symbol $K$; while the reactivity is denoted by $(\delta K) = K - 1$.

Fast-fission reactors require a predominating proportion of the uranium-235 isotope in their design, as the 238 isotope can absorb high-energy neutrons quite strongly without fission occurring. Thermal reactors overcome this difficulty by surrounding the uranium in which the fission occurs by a moderator, the function of which is to absorb the energy of the neutron in a series of scattering collisions. Neutrons of thermal energy (about a fortieth of an electron-volt) are only slightly absorbed by uranium-238. The size of such a reactor is quite large, the mass of 'natural' uranium in the Harwell British Experimental Pile known as BEPO being forty tons and the mass of moderator (graphite in this case) eight hundred tons; 'natural' uranium occurs in the proportions 140 parts of uranium-238 to 1 part of uranium-235. The critical size of a thermal neutron reactor may be reduced by artificially increasing the proportion of uranium-235 present in the uranium, and this sub-type of thermal reactor is known as an enriched reactor.

The third reactor-type employs a neutron energy for causing fission intermediate between fast and thermal, that is, some moderator is used. This is known as an intermediate reactor, and is likely to have importance for mobile nuclear power-plants.

The most important characteristic of a reactor is its neutron balance. A typical balance-sheet for a graphite-moderated thermal neutron reactor is as follows:

| | |
|---|---|
| Neutrons produced in fission of uranium-235 and in fast fission | 2·56 |
| Neutrons carrying on the chain reaction | 1 |
| Neutrons absorbed in uranium-238 to produce plutonium-239 | 0·9 |
| Neutrons absorbed in uranium-235 to produce uranium-236 | 0·2 |
| Neutrons absorbed in moderator | 0·3 |
| Neutrons absorbed in structural materials | 0·05 |
| Neutrons escaping from core | 0·09 |
| Excess neutrons | 0·02 |
| | 2·56 |

Temperatures and neutron-absorbing properties of fission residues affect this balance-sheet and adequate excess $K$ must be allowed for. Since, however, steady-state operation means that $K = 1$, control rods have to be provided to absorb any excess of neutrons not required at any particular time.

The plutonium-239 mentioned on the balance sheet can be split by slow neutrons, so that this provides a means of utilizing some of the uranium-238 in addition to the uranium-235. An ideal reactor would produce more secondary fuel (that is, plutonium-239) than primary fuel burnt (that is, uranium-235). With such a 'breeder' reactor we could expect to burn up a great part of the uranium-238.

Having briefly surveyed the principles of nuclear reactor operation, Sir John Cockcroft then discussed some of the technical problems of reactors, under the four groupings of physical, metallurgical, chemical and engineering. The physicists are responsible for the calculations of critical size, supplemented and checked by 'exponential experiments' on a sub-critical reacting-core. They must also determine the adequacy of the means of control and the shielding required. Metallurgists are concerned with the preparation of the uranium fuel elements. Due to the peculiar lattice-structure of uranium, serious distortion may be caused by thermal cycling and exposure to radiation. The uranium is sheathed in a suitable metal to seal it completely, and this metal must resist radioactive irradiations, not absorb too many neutrons and withstand the temperatures required by the engineers. Chemical reactions may be accelerated under irradiation, and chemists are required to study corrosion effects between reactor materials. The engineers have to weave together all these components into a feasible design, including the heat-transfer arrangements, the provision of adequate cooling in all circumstances, control and safety.

Turning next to reactors for producing power, Sir John distinguished between the production of substantial quantities of economic power and the development of specialized power-units, for example, for ship propulsion. The first stage in achieving the former target might well be the construction of thermal neutron reactors using natural uranium as a fuel, and either heavy water or graphite as a moderator. Design studies of this type of plant indicate that sizeable blocks of power could be generated at 20–25 per cent efficiency and that, making the conservative assumption that the capital cost of the nuclear station would be twice that of its coal-fired counterpart, and taking realistic figures for the cost of uranium, the cost of the power generated would not be greatly different from conventional practice.

Sir John stressed that no credit is allowed in the above figures for the value of the residual plutonium. If, for example, of the uranium-235, one-third were consumed, or 2·3 kgm./ton, the reactor would have produced 1·5–2 kgm. of plutonium per ton. This would then be available as a basic fuel for the second stage of the power development programme, the breeder reactor stage.

The first approach to breeder reactors will be to develop fast-fission reactors for this purpose, taking advantage of the greatly reduced absorption of fast neutrons by the materials of construction in reactors, and probably using plutonium as the fuel because its average neutron release is nearer 3 than 2·55. An experimental power-producing fast reactor has been working for some time in the United States and made up of a core, "about the size of a regulation football", consisting of uranium with a very high proportion of uranium-235 canned in some suitable metal. The heat developed by the burning of the uranium-235 is removed by the circulation of liquid sodium – potassium alloy. The liquid metal passes through a heat exchanger, and steam is developed to drive a 250-kW. power unit. It has not been made public whether breeding has been achieved, although it is said to be "a promising youngster".

Sir John next reviewed the contribution of nuclear power to the resources of world energy, taking his figures (which are in $10^{18}$ B.Th.U.) mainly from the recent report of the Materials Policy Commission to the President of the United States: the present world annual output of energy is 0·2; the world reserves of coal are United States 7·6, Canada 2, United Kingdom 1, China 6, U.S.S.R. 10 and others 6, the whole totalling 33; and the total world reserves of oil are, proved 1 and unproved 4·6, totalling 5·6. The same report estimates that about 25 million tons of uranium are available if we are prepared to pay 100 dollars per lb. of uranium in the ore. If breeding and 100 per cent utilization of uranium were achieved, this would add 1,700 × $10^{18}$ B.Th.U. to world reserves. If we were prepared to pay only 50 dollars/lb., the available reserves would be 250 × $10^{18}$ B.Th.U. Even at the higher figures, the primary fuel cost would be negligible if breeding were successful. This can be seen at once, since, on these assumptions, the needs of the United Kingdom can be met by 10–15 tons uranium a year at a primary fuel cost of less than 10 million dollars.

In conclusion, Sir John said that the time is not far off when nuclear power using natural uranium fuel will become feasible. These plants would work at reasonable efficiency and would produce power probably at a cost not very much more than from conventional power stations. This would seem to be sufficient to ask from the first experimental units, as all experience shows that costs may be expected to come down as experience accumulates.

Sir John Cockcroft was followed by Mr. R. V. Moore, who introduced his paper on "The Control of a Thermal Neutron Reactor". The operating characteristics of such a reactor were described, both on theoretical grounds and in the light of five years of operation of the Harwell reactors. The importance of the phenomenon of delayed neutrons on the controllability of the reactor was emphasized, and the following self-induced changes in the reactivity of the system were described: fuel depletion due to burning of uranium-235; poisoning due to the accumulation (owing to fission of uranium) of elements near the centre of the periodic table, certain of these elements (notably xenon-135) being powerful neutron-absorbers; and effects of temperature on reactivity.

The large thermal capacity inevitable with this type of reactor was mentioned, being illustrated by temperature – time curves for BEPO. The self-stabilizing phenomena of thermal reactors were described—that is, if the reactivity is increased for any reason so that the pile becomes divergent, by suitable design the reaction can be made to terminate itself. This is because the temperature coefficients are negative—namely, increased temperature involves a self-induced diminution of reactivity. Conditions at starting up and shutting down a reactor were described, as special safety considerations then apply. When starting up, there is an interval during which the neutron density is being raised from an infinitesimal level, which normally applies in the sub-critical state, to the lowest level that the installed instruments are capable of measuring. It is important that the reactor should arrive at this lowest detectable level still diverging sufficiently slowly to enable control to be established. If the reactor has been allowed to acquire excessive reactivity during this 'blind' period, the rate of divergence might be dangerous. On the other hand, advanced types of thermal reactor must be equipped with considerable potential reactivity to counteract the self-induced changes already mentioned. It was Mr. Moore's suggestion that this difficulty could be safely resolved by limiting the rate at which the reactivity might be increased. By studying the self-induced changes, a rate of withdrawal of the control rod may be determined which is normally adequate to compensate these, but which avoids the dangerous start-up condition. At shut-down the difficulty arises that the nuclear reaction cannot be completely cut off at will. This implies that adequate cooling to balance the residual heating must always be available.

The paper concluded by postulating various fault conditions and examining their consequences, and it was Mr. Moore's conclusion that a system of control for thermal nuclear reactors could be evolved which would be inherently safe.

Mr. J. H. Bowen then introduced his paper on "Automatic Control Characteristics of Thermal-Neutron Reactors". From an operating point of view, it is a convenience to abolish all consideration of the rather complex relation between the variation of reactivity and the subsequent variation of power, by installing an automatic power-controller. This device measures the instantaneous reactor power-level and adjusts the reactivity to bring the power automatically to some predetermined or desired level. The differential equations describing the operation of this device include terms involving the response of the reactor to variation of reactivity. These terms, described in the paper as the reactor "transfer function", have been obtained analytically and confirmed by experiment. Typical complete control-system responses have been calculated and checked by experiment, with good agreement, and a design method for reactor control-systems was suggested.

The final paper, "Neutron Detectors for Reactor Instrumentation", by T. A. J. Jaques, H. A. Ballinger and F. Wade, was introduced by Mr. Jaques. It discussed the principles involved in the detection of thermal neutrons and described two new types of detector recently developed in connexion with the operation of thermal reactors. The first is mainly used as a flux-scanning detector—that is, for local measurements of flux density—and is essentially a thermopile with its hot and cold junctions placed adjacent to each other to share equal ambient temperature conditions. One set of junctions, however, is embedded in boron. Under neutron irradiation, the boron – neutron reaction causes unbalanced heating of the junctions, and the instrument thus develops a thermal E.M.F. proportional to the neutron flux density. The response time-constant is of the order of ten seconds.

The second new type is an ionization chamber. These chambers are normally slightly sensitive to incident gamma-ray radiation, in addition to the intended response to neutron flux. This effect has some importance when the reactor is operating at low power following conditions of high-power running, since the residual gamma-radiation may then be comparatively intense whereas the neutron flux is weak. The new chambers are intended partially to overcome this difficulty by measuring separately the gamma-radiation and the neutron-plus-gamma-radiation. The former measurement is then automatically subtracted from the latter to leave the quantity required.

In opening the discussion which followed these papers, Dr. Dennis Taylor suggested the use of pulse counters at start-up. These could best be used in conjunction with a logarithmic rate-meter, and the possibility then exists of obtaining directly a measure of the pile reactivity. A period-meter or reactivity-meter of this sort is under development at Harwell. When considering extending the range of power measurements, an inevitable question which arises is whether or not electrometer valves can be considered sufficiently reliable for important applications. In this connexion Dr. Taylor reported the experience gained on BEPO: in the past two years not a single failure due to electrometer valves has been recorded in the log-book.

Dr. A. Lundby (Norway) stated that, in the operation of a heavy-water thermal reactor, photo-emission of neutrons from deuterium by gamma-radiation has some important effects on reactor control. He believed that the gamma-radiation mainly responsible for this effect is due to the reaction Ba $\rightarrow$ $^{140}$La which has a period of 12·8 days.

Mr. R. Westergaard (Sweden) suggested that Mr. Bowen's paper would be improved by the consideration of the effects of time delays at various points in the system. In particular, he had in mind the use of pulse counters or rate-meters for power measurements at low flux, as this provides an excellent method of discriminating against gamma-radiation. But the statistical fluctuations involved in such measurements can only be reduced by rather long integrating-times at the rate-meter, and this must involve corresponding time delays in the automatic-control loop.

Referring to Section 8 of Mr. Moore's paper, M. M. Surdin (France) said that it is the practice to start up the French reactors in the manner suggested, namely, by slowly withdrawing the control rods at constant speed. This speed has been chosen so that the maximum reactivity during the starting transient will not exceed the arbitrary value of 0·3 per cent. This speed corresponds to a rate of reactivity increase of $10^{-3}$ per sec. In this connexion he referred to a calculation by M. M. Ravievski which showed that, when starting up in this manner, the power at which the critical condition is reached depends only on the rate of reactivity increase. (It may be noted here that similar calculations by J. Woodrow, of Harwell, show that this power is also proportional to the spontaneous or starting power in the shut-down state.)

Mr. W. Kealy (Department of Atomic Energy) made the comment that a reactor entirely devoted to isotope production would be controlled to work continuously at maximum power. This would be limited by temperature considerations, and it is found in practice that fluctuations in the frequency of the electricity supply are sufficient to vary these temperatures by as much as 6 per cent. The system of automatic power control described in Mr. Bowen's paper has to be supplemented by a temperature-sensitive control which, in fact, adjusts the set point of the power controller.

Reference was made by Mr. L. C. Ludbrook (British Thomson-Houston Co., Ltd.) to a few experiments he has made in connexion with the design of a reactor-power controller. These lead to a reactor transfer function in close agreement with Mr. Bowen's, although the approach has been entirely different.

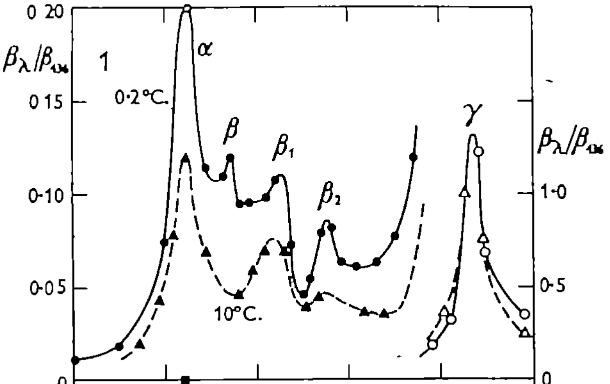
Mr. S. A. Ghalib (Metropolitan-Vickers Electrical Co., Ltd.) said that, in addition to the corrosion problems mentioned by Sir John Cockcroft, a further difficulty for engineers in reactor design work is the problem of friction and wear in these mechanisms, which have to function, often without lubrication and maintenance, in the gas chosen as the reactor coolant. Another point concerns the range of the level of reactor power, quoted in Mr. Moore's paper, as $10^{14}$. This obviously applies between the shut-down and full-power states, but Mr. Ghalib suggested that in normal power-producing operations a range of 20 to 1 would be more probable.

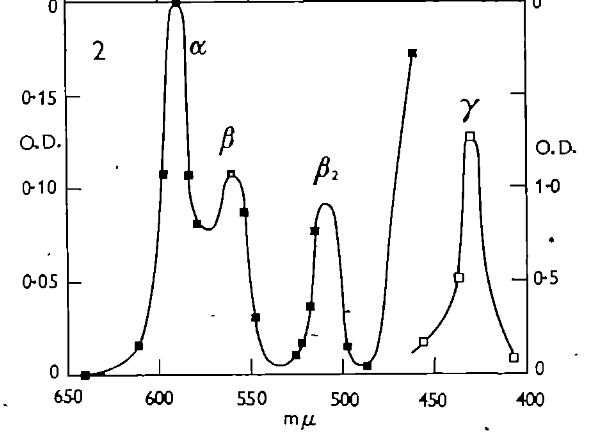
---

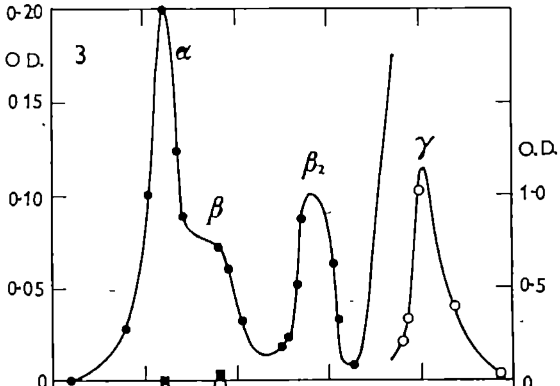
# CYTOCHROME OXIDASE AND THE 'PASTEUR ENZYME'

By PROF. D. KEILIN, F.R.S., and DR. E. F. HARTREE
Molteno Institute, University of Cambridge

IT was shown in 1925 that the multibanded absorption spectrum of cytochrome belongs to three hæmochromogen-like components, denoted as cytochromes *a*, *b* and *c*, the oxidation and reduction of which—that is, their catalytic activity in respiration—can easily be observed in living intact cells[1]. However, further spectroscopic studies[2] of the activity of a typical cytochrome system in heart muscle preparations or in suspensions of certain micro-organisms in the presence of different substrates and inhibitors revealed that the absorption bands, at about 605 mμ and 448 mμ (α- and γ-bands), do not belong solely to cytochrome *a* but represent the superimposed and fused bands of two cytochrome components *a* and $a_3$. Cytochrome $a_3$, unlike cytochromes *a*, *b* and *c*, is very autoxidizable and combines reversibly with respiratory inhibitors such as cyanide, azide, hydrosulphide and carbon monoxide. These properties of cytochrome $a_3$, together with the fact that the absorption bands of its carbon monoxide derivative (α 590 mμ, and γ 432 mμ) occupy approximately the same position as the α- and γ-bands in the photochemical absorption spectrum of yeast[3,4], enabled us[2] to identify it with cytochrome oxidase or Warburg's "respiratory ferment". Cytochromes *a*







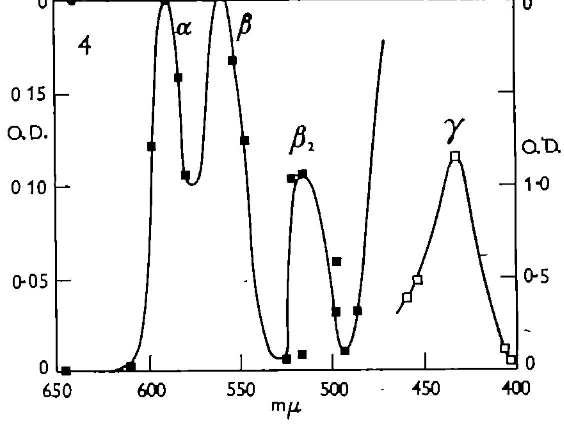


Fig. 1. Relative photochemical absorption spectra of *Torula utilis* at 0·2° and 10° C. from data of Kubowitz and Haas (ref. 4). Ordinate scale reduced ten-fold for Soret or $\gamma$-bands in Figs. 1–5

Fig. 2. Relative photochemical absorption spectrum of bakers' yeast replotted from data of Melnick (ref. 5) with ordinate scale adjusted as described in the text. O.D. = optical density

Figs. 3 and 4. Relative photochemical absorption spectra with adjusted ordinate scale: (3) heart muscle preparation + succinic acid from data of Melnick (ref. 6); (4) area vitellina of chick embryo from data of Philips (ref. 8)

and $a_3$ probably have identical chemical structures so far as both the hæm and protein are concerned. The difference in their reactivities may be due to differences in the mode of attachment of the hæm to the protein.

Since the introduction of a photochemical method[3] for the study of the absorption spectrum of the carbon monoxide derivative of the 'respiratory ferment', photochemical absorption spectra have been obtained for *Torula utilis* and *Acetobacter pasteurianum* by Warburg and Negelein[3] and by Kubowitz and Haas[4], for bakers' yeast and a colloidal heart muscle preparation by Melnick[5,6], and for the area vitellina of the chick embryo by Philips[7,8]. To this list can be added two photochemical absorption spectra ascribed to the 'Pasteur enzyme': one obtained for rat retina by Stern and Melnick[9], and the other for bakers' yeast by Melnick[9].

The very limited use that has so far been made of the photochemical method since its introduction more than twenty years ago[3] is not due solely to its elaborate and specialized technique but also to certain restrictions in the type of material which can be studied by this method. In fact, the respiration of cells and tissues, even when it depends upon the cytochrome system, is not always inhibited by carbon monoxide, and, when a marked inhibition by carbon monoxide is obtained, it is by no means invariably reversed by light. Moreover, in micro-organisms the components of cytochrome, including cytochrome oxidase, may show marked variations in absorption spectra and other properties.

## Comparative Study of Photochemical Absorption Spectra

Of the photochemical absorption spectra so far recorded, those obtained by Kubowitz and Haas[4] are of special interest since they are based upon determinations at thirty different wave-lengths ranging from 253 to 671 mμ.

In order to compare the absorption spectra enumerated above and to bring into evidence the characteristics they have in common, they have been replotted (Figs. 1–5) in the following manner. The height of the $\alpha$-band was taken as a point of reference, and the optical densities were recalculated to give equal densities of 0·20 at the peak of the $\alpha$-band. This figure is the value for $\beta_{587}/\beta_{436}$ obtained by Kubowitz and Haas[4] in their determination of the photochemical absorption of *T. utilis* at 0·2°. Examination of these absorption spectra reveals marked variations in the number, shape, positions and the relative heights of the bands. Among the most striking features of these spectra are the following: the great complexity of the absorption spectrum in the visible region of *T. utilis* recorded by Kubowitz and Haas[4] at 0·2° C. (Fig. 1); the prominence of $\beta_2$ bands in the remaining spectra, including those ascribed to the 'Pasteur enzyme'; the obliteration of the $\beta$-band in the heart muscle preparation (Fig. 3); the unusually high $\beta$-band in the case of the chick embryo (Fig. 4) where this band is, if anything, higher than the $\alpha$-band and where the trough between $\alpha$- and $\beta$-bands is unusually deep for

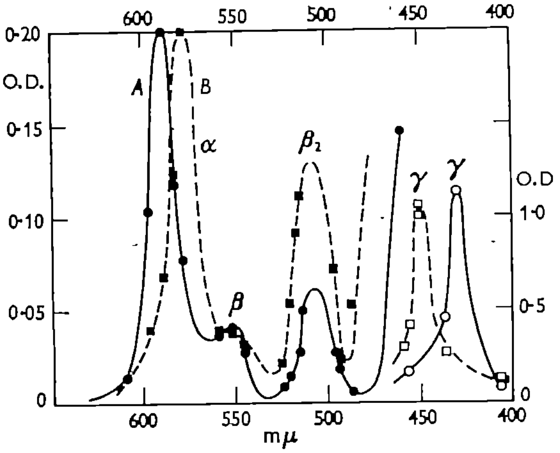

Fig. 5. Relative photochemical absorption spectra of the 'Pasteur enzyme' with adjusted ordinate scale: (*A*) bakers' yeast from data of Melnick (ref. 5); (*B*) retina of rat from data of Stern and Melnick (ref. 9)

the carbon monoxide derivative of a hæmoprotein; the position of the γ-band in the photochemical absorption spectrum of the heart muscle preparation which is at about 450 mμ, whereas direct spectroscopic study of this preparation revealed that on treatment with carbon monoxide the γ-band of cytochrome $a_3$ moves from 445 to about 432 mμ [2].

The differences between the photochemical absorption spectra of the 'Pasteur enzymes' (Fig. 5) in bakers' yeast (*A*) and retina (*B*) are much more marked than the differences between either of them and some of the photochemical spectra of the 'respiratory ferment'. In fact, the spectra of the 'Pasteur enzyme' and of the 'respiratory ferment' in bakers' yeast (Figs. 5 and 2), as determined by Melnick[5], are virtually identical except that the β-band is much lower in the 'Pasteur enzyme' spectrum, where it is more comparable with the β-band of the 'respiratory ferment' in the heart muscle preparation (Fig. 3). On the other hand, the γ-band of the latter and of the 'Pasteur enzyme' of the retina (Fig. 5,*B*) were recorded at 450 mμ, which is 18–20 mμ nearer the red end of the spectrum than the corresponding bands in all the other photochemical absorption spectra. Thus, an analysis of the photochemical absorption spectra does not support the view that the 'Pasteur enzyme' and cytochrome oxidase are two distinct enzymes. Similar doubts as to the distinction between the two enzymes have already been expressed by Dickens[10].

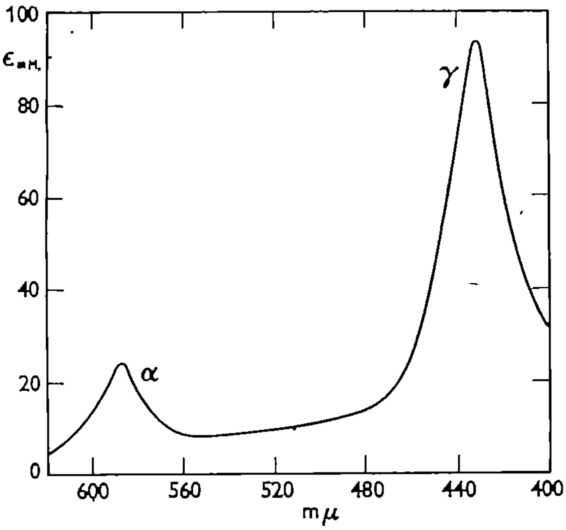

Fig. 6. Absorption spectrum of pyridine hæmochromogen obtained from hæmatin of cytochrome *a* (after Rawlinson and Hale (ref. 13))

## Interpretation of the Photochemical Absorption Spectra

The foregoing discussion of the photochemical absorption spectra suggests the following possible explanations of their great complexity and variability.

(*a*) The lack of agreement between the curves may be due to experimental errors inherent in the method and to great technical difficulties in its application. This is partly supported by marked differences in the spectra recorded for *T. utilis*[4] at 0·2° and 10° C. (Fig. 1).

(*b*) It is, on the other hand, possible that the differences in the spectra are genuine and that they reflect differences in the structure of the cytochrome oxidase of different cells, such as would be expected to arise from variations of the protein portion of its molecule. However, this would scarcely explain the marked differences in the spectra obtained for *T. utilis* and bakers' yeast, or for the heart muscle preparation and the chick embryo.

(*c*) Finally, one cannot exclude the possibility that, although in the main the photochemical absorption spectrum represents the carbon monoxide compound of cytochrome oxidase, the complexity and variability of the spectrum may reflect the influence upon it of light absorption by other intracellular components, and in particular by the cytochromes that are intimately linked with the oxidase. This hypothesis is supported by the presence of the protein band in the photochemical absorption spectra of *T. utilis* and *A. pasteurianum* recorded by Warburg and Negelein[3], by Kubowitz and Haas[4] and by the recent finding by Bücher and Kaspers[11] of the protein band in the photodissociation spectrum of carbon monoxide myoglobin. In all these cases the light energy absorbed by tyrosine and tryptophane residues of the protein at about 280 mμ is transmitted to the hæm and utilized for photodissociation of the iron – carbon monoxide link in the same way as light energy absorbed directly by the hæm nucleus.

Considering that all components of the cytochrome system are intimately linked together through their proteins, which probably provide suitable pathways for electron transfer from the iron of one to that of another component, it is conceivable that some of the light energy absorbed by components which react neither with oxygen nor with carbon monoxide may nevertheless be transmitted to carbon monoxide–cytochrome oxidase compounds of *Torula* and *Acetobacter* and be involved in their photodissociation in the same manner as light energy absorbed by tyrosine and tryptophane of the protein. Such a possibility may help us to understand the remarkable difference between the complex photochemical spectra and the simple one-banded absorption spectrum in the visible region of the pyridine hæmochromogen obtained from hæm *a* and $a_3$ by Negelein[12], by Rawlinson and Hale[13] (Fig. 6), and by Dannenberg and Kiese[14]. We have found, in addition, that the globin hæmochromogen of hæm $a + a_3$ shows the same single band at about 587 mμ which, in presence of carbon monoxide, shifts slightly towards the red end of the spectrum[15].

The foregoing view of the nature of the photochemical absorption spectra allows a simpler interpretation of their variability, since the relative proportions of the cytochrome components vary from one kind of cell to another[1]. The contribution to the photodissociation of the cytochrome oxidase – carbon monoxide compound by other components of the cytochrome system and possibly by some other light-absorbing substances would, in these circumstances, be a variable one. On the other hand, if more than one hæmoprotein contributes to the photochemical spectrum in the Soret region, the experimental γ-band should be somewhat asymmetric with shoulders representing the smaller contributions of components other than cytochrome oxidase. Unfortunately, sufficient data to decide this matter are not available, nor could they be easily obtained, since many experimental points would be required within a very limited spectral region to provide the exact shape of the γ-band.

However, the problem whether the carbon monoxide compound of cytochrome oxidase does exhibit a multibanded spectrum in the visible region, as the photochemical spectra appear to suggest, will be finally solved either by study of the isolated and purified native cytochrome $a$ and $a_3$ hæmoproteins completely free from other native or denatured hæmoproteins, or by the study of absorption spectra of carbon monoxide complexes of compounds reconstructed from hæm $a$ and different proteins. Until this is accomplished, the most plausible explanation of the great complexity and variations of the photochemical absorption spectra lies in the assumption that several light-absorbing components of the catalytic system contribute to the pattern of these spectra.

Since all the components of the cytochrome system are intimately linked together to form an integral part of certain structural elements of the cell such as mitochondria or sarcosomes, it is conceivable that the spatial distribution of cytochrome oxidase in relation to the other cytochrome components and other oxido-reduction systems varies from one structural element to another, or from one region of the same element to another. According to its localization, cytochrome oxidase may be linked in different manners and in different proportions to other components of catalytic systems and therefore may not be equally saturated in each case with electron donors. It is only in places where cytochrome oxidase is fully saturated with electron donors that its activity can become the rate-determining step and that its susceptibility to carbon monoxide will be reflected in the over-all reaction in which it takes part. This may explain the differences in the susceptibility to carbon monoxide of respiration and the Pasteur reaction discovered by Laser[16]. Thus his important observation that in certain tissues it is not the respiration but the Pasteur reaction that shows light-sensitive inhibition by carbon monoxide does not necessarily imply the existence of a specific 'Pasteur enzyme' which is distinct from cytochrome oxidase.

It is therefore reasonable to assume that cytochrome oxidase is the component, showing the light-sensitive inhibition by carbon monoxide and the photochemical absorption spectrum, of the catalytic system involved in the Pasteur reaction. As to the susceptibility of this reaction to other factors[16], which do not affect cytochrome oxidase, it may well be due to their action upon some other components of the catalytic system responsible for this reaction.

# OBITUARIES

## Prof. W. H. Hobbs

William Herbert Hobbs was born at Worcester, Massachusetts, on July 2, 1864, and died at Ann Arbor, Michigan, early in January 1953. He was educated at the Worcester Polytechnic Institute, where he made a special study of industrial design. Upon graduation in June 1883 he taught for a year at a country school, and then went to Johns Hopkins University at Baltimore to study first chemistry and physics and later geology, in which he took his degree in 1888. After a year's postgraduate work at Heidelberg, Hobbs returned to the United States as an instructor in the University of Wisconsin and curator of the geological museum there. In 1891 he was appointed assistant professor of mineralogy and petrology, and nine years later became full professor. Between 1885 and 1900 he was also employed from time to time by the United States Geological Survey in New England, and made a special study of methods of discovering faults by means of surface relief. Hobbs was in Italy at the time of the Calabrian earthquake in 1905 and formed the opinion that there was no epicentrum, or centre of heavy shock, but many intersecting 'seismotectonic' lines of shock with the heaviest shocks at their junctions. He published this novel conclusion in "Earthquakes: an Introduction to Seismic Geology" (New York, 1907).

As a result of these investigations, Hobbs had become more interested in dynamic and structural aspects of geology than in mineralogy and petrology, and in 1906 he accepted the post of professor of geology at the University of Michigan, where he remained until retirement in 1934. He first became interested in glaciology in 1906, when he visited Switzerland, and five years later published "Characteristics of Existing Glaciers" (New York, 1911), in which he emphasized the wide differences between valley glaciers and ice sheets.

Hobbs was a keen traveller and spent much time in Europe, North Africa and on the islands of the Pacific Ocean. In 1926, when he was more than sixty, he led the first University of Michigan Expedition to Greenland. His object was to find evidence in support of his belief that a permanent 'glacial anticyclone' over Greenland governs atmospheric circulation in the northern hemisphere. Although his hypothesis was later shown to be inconsistent both with the observed facts and the theory of the polar front, Hobbs continued to assert that the characteristic circulation of the northern and southern hemispheres depends upon the existence of the ice sheets of Greenland and Antarctica, acting as downshafts for the restoration of air to lower latitudes. Again, in 1927 and in 1928, he led parties to southwest Greenland, and later published a general account of their achievements in "Exploring about the North Pole of the Winds" (New York, 1930). During the Second World War it was Hobbs who suggested Søndre Strømfjord, where his expeditions had worked, as a site for the United States air base which came to be known as Bluie West Eight.

After his retirement Hobbs turned his attention to the historical aspects of polar exploration. As might be expected, he had entered whole-heartedly into the bitter controversy between Frederick A. Cook and Robery E. Peary, and wrote a biography entitled "Peary" (New York, 1936) in vehement support of the American admiral's attainment of the North Pole. Hobbs also devoted much attention to the discovery of the antarctic continent, and published the results of his investigations in 1937. In exceptionally harsh and acrid terms he sought to show that it was an American sealer, Nathaniel Brown Palmer, who first sighted Antarctica, although there is no doubt whatever that Edward Bransfield was, in fact, the first to do so. Hobbs's attempt to discredit men like Bransfield and James Weddell, and his ruthless misrepresentation of original documents, was a source of great embarrassment to his many friends in Britain.

Whatever doubt there may be as to the worth of Hobbs's contribution in some fields, of his vigour and enthusiasm there can be no question. He was never afraid to state his views, however controversial; but it is regrettable that he was so rarely prepared to admit, in the face of overwhelming evidence, that he had been mistaken. J. D. M. BLYTH

## Prof. David Katz

THE death of Prof. David Katz on February 2 at the age of sixty-nine removes from psychology a gifted and versatile experimentalist of the first rank. Born in Cassel, Hessen-Nassau, in 1884, he studied natural science and mathematics at Göttingen and later turned to psychology, under the direction of G. E. Müller. It was characteristic of him that his interest in psychology was aroused by acting as a subject in an experiment. He pursued these early studies at Munich and Berlin, and it was during this time that he came under Husserl's influence, which remained throughout his life. On receiving his doctorate in 1906, he spent some months in military service and then proceeded to Munich, where Theodore Lipps was a focus of interest, and afterwards to Würzburg, where Kulpe's laboratory was the main attraction.

He took up his first appointment at Göttingen in 1907 as G. E. Müller's assistant, and remained there until the outbreak of the First World War, when he enlisted and served for nearly four years. In 1918 he had the opportunity of working for some time at the Engineering School in Hanover, being engaged in the study of sensory-motor reactions of Sauerbruch amputees, thus introducing psychological methods into the field of prosthesis.

In 1919 he married Rosa Heine, a psychologist in her own right, who has always been closely associated with her husband's work, particularly on child and animal behaviour.

In the same year Katz accepted the new chair of psychology and education at the University of Rostock. He stayed there until 1933 when he was forced to leave because of the Nazi regime. Fortunately, an invitation was extended to him to work in Prof. T. H. Pear's laboratory in the University of Manchester and later in Sir Cyril Burt's Department at University College, London. While in England he also carried out experiments on monkeys at the London Zoo and for two years acted as psychological adviser to the British Research Association of Flour Millers. In 1937, he was appointed to the first chair of pedagogy and psychology in the University of Stockholm, where he remained until his retirement in 1951.

The wide scope of Katz's experimental interests is indicated by his original work on sense perception (especially colour-vision, touch, taste and vibration), child development, processes of thought and learning, and animal behaviour. He preserved until the end an originality and freshness of approach in all his varied work, and his writings are characterized by simplicity, directness and lucidity.

During 1930–33 he was co-editor of the *Zeitschrift für Psychologie*. In 1950, he went to the University of California to deliver the Hitchcock Lectures, and in 1951 he was president of the Thirteenth International Congress of Psychology. His numerous publications include "Psychologie und Mathematische Unterricht", "Studien zur Kinderpsychologie", "The World of Colour", "The World of Touch", "Hunger and Appetite", "Conversations with Children" (jointly with Rosa Katz), "A Psychological Atlas", "Gestalt Psychology", and "Animals and Men".

Prof. Katz possessed great charm of personality and a sense of humour, and his unfailing kindness won him numerous friends in many countries. He leaves a widow and two sons. JOHN COHEN

## Dr. Edward Hope

DR. EDWARD HOPE, who died at Caterham on February 7, was born on December 19, 1886, and received his chemical training under W. H. Perkin, jun., at the University of Manchester. His earliest researches included studies in the preparation and reactions of several interesting alicyclic and aliphatic acids, as well as some notable investigations, conducted in collaboration with Sir Robert Robinson, in the narcotine and gnoscopine group of alkaloids.

Perkin had moved to Oxford in 1913, and, during the First World War, British Dyes, Ltd., organized a team of chemists to investigate, under his direction, difficulties which had arisen in the manufacture of dyes and their intermediates. Hope went to Oxford in 1916 to join this team and worked in the newly opened Dyson Perrins Laboratory. In 1919 he accepted an appointment as lecturer and demonstrator in the new laboratory, and at the same time became a Fellow and tutor in chemistry at Magdalen College.

The immediate post-war period was one of considerable reorganization and development in the chemistry school at Oxford. The research year had just been introduced as an integral part of the honours course, and Hope applied himself wholeheartedly to the problems of the laboratory and the needs of a large body of pupils at Magdalen. He maintained his interest in research and published a number of papers jointly with his students, mostly on the chemistry of substances related to the indigo dyes; but he was carrying a heavy burden of work and showed early signs of the ill-health which marked his later years. Although he found it necessary to relinquish his teaching duties at Magdalen in 1933, he remained at the College, where he filled various offices and ultimately became Senior Fellow. He continued his work at the Dyson Perrins Laboratory as a University demonstrator and lecturer until he reached the normal age of retirement in September of last year. For many years he edited the "Chemists' Year Book".

Hope will long be remembered with affection by his pupils and colleagues. He was a popular and successful tutor, and countless numbers of Oxford chemists will recall with gratitude the friendly advice and encouragement which they received from him in the laboratory. S. G. P. Plant

# NEWS and VIEWS

## Organic Chemistry in the University of Leeds: Prof. F. Challenger

Prof. F. Challenger, who retires from the chair of organic chemistry in the University of Leeds at the end of the present session, studied under Jamieson Walker, Kipping and Wallach, and held appointments in the Universities of Birmingham and Manchester before succeeding Ingold at Leeds in 1930 (see *Nature*, 126, 187; 1930). He has seen the department move from its old outgrown quarters to the present large building, opened in 1933, and has seen that in turn strained to the utmost to contain the greatly increased numbers of post-war students. However, university expansion with its concomitant administrative problems has not kept Challenger away from the laboratory bench, nor has he shared the post-war doubts of some about the aims of a university; whether in the Senate, in the chair at the Ph.D. Committee, or in discussion with individual students, his influence has always been emphatically on the side of the pursuit of new knowledge. Challenger's friendly and generous disposition has not only established good relations between the Chemistry Department in Leeds and those elsewhere (particularly the Dutch schools of organic chemistry), but has also shown itself in the way he has helped a succession of postgraduate students who have worked with him, and in his unfailing courtesy and kindness to his colleagues.

Challenger's researches have been concerned principally with biological methylation and with the synthesis, structure and properties of heterocyclic sulphur compounds, particularly the thiophthens, the solid isomer of which he was the first to isolate. His studies of the methylating properties of moulds have revealed many interesting reactions, such as the fission and methylation of organic disulphides, the production of alkyl mercaptans from methionine and alkyl cysteines, as well as the methylation of inorganic and organic compounds of arsenic, selenium and tellurium. The last-named reaction is analogous to that which takes place in animals. His views on the similarity of the transmethylation mechanism in moulds and in animals have recently been confirmed by his own elegant experiments with compounds labelled with carbon-14. With Dr. Simpson he showed that the dimethyl sulphide evolved by the marine red alga *Polysiphonia fastigiata* arises from the decomposition of the thetine $(CH_3)_2\overset{+}{S}.CH_2.CH_2\,COO^-$; this compound, the first of its class to be found in plants, was shown later by du Vigneaud and by Dubnoff to act as a methyl donor in the conversion of homocysteine to methionine in rats, and a valuable link was thus forged between the parallel investigations in Leeds and Cornell. He has also demonstrated the presence of dimethyl sulphide (shown by Haas to occur in *Polysiphonia*) in numerous other plants.

### Dr. B. Lythgoe

Dr. B. Lythgoe, who succeeds Prof. Challenger, is a Lancashire man. He was educated at Leigh Grammar School and the University of Manchester, where he graduated in 1934, and commenced postgraduate work in organic chemistry under the leadership of Sir Ian Heilbron. In this early phase of his career he was introduced to the chemistry of natural products and made important contributions to the study of algal carotenoids, including the isolation of myxoxanthin, the characteristic pigment of the Myxophyceæ. After a brief spell in industry, Dr. Lythgoe joined the staff of the Chemistry Department at Manchester in 1938, and there he began an association with Prof. A. R. Todd which, starting with some vitamin studies on the liver filtrate factor (pantothenic acid), developed into a co-operative attack on the problem of nucleoside structure. In a series of well-known investigations, spread over a number of years, the structure of the natural ribonucleosides was completely elucidated and their synthesis effected. It was during the development of this field that Dr. Lythgoe moved in 1944 with Prof. Todd to Cambridge, where he is at present lecturer in chemistry and a Fellow of King's College.

Parallel with the development of the work on nucleosides in Cambridge, Dr. Lythgoe's wide ranging interest in natural products caused him to initiate a series of brilliant researches on some unusual natural toxic principles, including the remarkable substance macrozamin, obtained from members of the Cycadaceæ, which he showed to be a derivative of azoxymethane, and the acetylenic substances responsible for the toxic effects of the British plants *Oenanthe crocata* and *Cicuta virosa*. These investigations and his other related studies have attracted much attention, both for their elegance in experimentation and for the theoretical insight which they display. Indeed Lythgoe's unusual combination of theoretical and natural product interests, coupled with his strong personality, assure a vigorous future for organic chemistry in Leeds.

## Royal Society of Edinburgh: New Fellows

At the sixth ordinary meeting of the Royal Society of Edinburgh held in the Society's Rooms, 24 George Street, Edinburgh 2, on March 2, the following were elected Fellows of the Royal Society of Edinburgh: Prof. F. Bell, Department of Chemistry, Heriot-Watt College, Edinburgh; Mr. L. J. F. Brimble, joint-editor of *Nature*; Prof. J. L. Burchnall, Department of Pure Mathematics, University of Durham; Dr. E. A. C. Chamberlain, divisional chief scientist, Scottish Division, National

Coal Board; Prof. C. G. C. Chesters, Department of Botany, University of Nottingham; Dr. A. Clow, British Broadcasting Corporation; The Right Hon. the Earl of Crawford and Balcarres; Mr. A. A. Fulton, chief hydraulic engineer, North of Scotland Hydro-Electric Board; the Right Hon. the Earl of Haddington; Dr. J. Heslop Harrison, lecturer in the principles of plant taxonomy, University of London; the Right Hon. the Earl of Home, P.C., Minister of State, Scottish Office; Dr. D. B. McIntyre, lecturer in petrology, University of Edinburgh; Mr. B. G. McLellan, formerly director of the Scottish Seaweed Research Association; Sir James Irvine Masson, formerly vice-chancellor of the University of Sheffield; Dr. A. D. Merriman, registrar-secretary of the Institution of Metallurgists, London; Dr. A. R. Mitchell, lecturer in applied mathematics, University of St. Andrews; Dr. A. T. Phillipson, deputy director and head of the Physiology Department, Rowett Research Institute, Bucksburn, Aberdeenshire; Mr. K. S. M. Rae, officer-in-charge, Oceanographic Laboratory, Edinburgh; Dr. Edith P. Smith, lecturer in botany, University College, Dundee; Dr. J. T. Stamp, head of the Veterinary Department and veterinary investigation officer, Edinburgh and East of Scotland College of Agriculture; Dr. D. M. Steven, lecturer in zoology, University of Edinburgh; Prof. M. M. Swann, Department of Natural History, University of Edinburgh; Principal T. M. Taylor, vice-chancellor of the University of Aberdeen; Prof. W. L. Weipers, Department of Veterinary Surgery, University of Glasgow; Dr. L. H. Wells, senior lecturer in physical anthropology, University of Edinburgh.

### Meteorological Expedition to the British West Indies

Prof. P. A. Sheppard, of the Department of Meteorology, Imperial College of Science and Technology, London, has recently left the United Kingdom to lead a small meteorological expedition from his department to Anegada (lat. 18° N., long. 64° W.) in the British Virgin Islands, British West Indies. The expedition, in which the National Institute of Oceanography is collaborating, is planning to study for about a month the transfer of momentum, heat and water vapour from the ocean into the Trade Wind air, to relate these transfers with the vertical variation of mean wind speed and direction in the first kilometre or two of the atmosphere and with the pattern and structure of Trade Wind cloud, mainly cumulus. This expedition follows an earlier expedition to the Scilly Isles during January 1951. There, momentum transfer processes were studied in the variable westerlies of middle latitudes, and the results indicated that the classical concept of the terrestrial friction layer, a layer half a kilometre or so in thickness, in which turbulence and momentum transfer drop off to zero at the top of the layer, needed revision. The results could be interpreted on the assumption that the momentum transfer was maintained or even increased with height by means of turbulence of moderate scale which was found to exist in the air. Unlike the classical boundary layer beneath a uniform stream of air, the wind speed in the westerlies increases with height up to the level of the tropopause, not through friction at the underlying ocean surface but because of the temperature drop towards higher latitude. In the Trade Winds a similar temperature drop causes easterlies near the surface to give way to westerlies (anti-Trades) aloft. This difference between Trade Winds and westerlies is likely to lead to markedly different patterns of momentum transfer in the two fields, a difference which if substantiated must be important in the understanding of the general circulation of the atmosphere. Anegada is a small low-lying island in a Trade Wind area, and the expedition will use it as a fixed platform to observe the variation in wind from one five minutes to the next, that is, the moderate-scale turbulence, in the first kilometre or two of the Trade air, using balloons. Time-lapse photography of the clouds will also be undertaken. The Woods Hole Oceanographic Institution in Massachusetts will collaborate with the Imperial College expedition by using an aircraft to take observations of cloud structure in the same region at the same time.

### Photoelectric Studies of the Night Sky Light

A paper by Masaaki Huruhata on "Photoelectric Studies of the Night Sky Light" has been published in *Tokyo Astronomical Observatory Reprints*, No. 89 (reprinted from the *Report of Ionosphere Research in Japan*, 6, No. 1; 1952), which describes the method of study of the horizontal drift of the night sky. The measured emission of the infra-red radiation between 8500 and 11000 A. was identified as due to the OH ion; this radiation is so strong that it can be easily measured over the whole sky without suffering from the effects of bright star-light. The instrument consists of a photoelectric photometer furnished with a cæsium cell, the current being amplified by the electrometer tube. An infra-red filter placed in front of the photocell cuts out the visual light shorter than 8500 A. Observations were carried out at Yawatano, Shizuoka-ken, and the results are plotted for each hour for various periods between January 1, 1949, and December 11, 1950. On most nights the drift of intense or weak clouds of the night sky could be recognized, the direction of drift being mostly from north-north-east to south-south-west or in the opposite direction, and this direction is perpendicular to the geomagnetic parallel. On December 23, 1949, the velocity of the drift was estimated to be 1,000 km./hr., but this appears to be exceptional and several hundred km./hr. seems to be the normal speed. It is remarkable that the speed of the southward drift averages about 20 per cent more than that of the northward drift. Attempts were made to find some correlations between drift and the position of the moon, on the theory that wind in the upper regions of the atmosphere—about 300 km. high—might be caused by tidal movements, but none could be found, nor could any correlation be found between the drift and the ionospheric and geomagnetic disturbances observed in Japan proper.

### Study of Forest Seeds in Sweden

An article by Einar Huss, entitled "Methods used in the Swedish Forest Research Institute in Seed Experiments", has been published in *Reports of the Forest Research Institute of Sweden* (*Meddelanden från Statens Skogsforskningsinstitut*, 40, 53; 1952), in which it is stated that during the past few years, owing to the growing interest in forest culture in Sweden, a thoroughgoing study of questions touching the appropriate methods of treating forest seed and the characters determining the effect on plant results has been undertaken. There were also the problems of supplying the forest industry with enough seed, because of the greatly increased demand, and the necessity, owing to this increased demand, of producing the best possible quality of seed, which is a commercially expensive commodity. There are few forestry departments in the world at the present day in which the demand for high-quality forest seed of many varying species does not exist, and, in the case of exotics, this often has to be imported. The objective of the study was to provide a "real average sample". At the beginning of the past decade, a new experimental selection method was introduced by Prof. Lars Tirén, director of the State Forest Research Institute's Forest Department, in the seed experiments of the Institute, which was described in 1948 in an essay published in the Institute's *Proceedings* (37, No. 5). Einar Huss's paper reviews the manner of treating cones and seed from Scots pine and Norway spruce. In eight short sections he deals with definitions and quantitative units, collection of cones, storage, selection, extraction of seed, de-winging and cleaning, sampling and germination. The ninth section treats of storage and the methods in use. The whole article merits close study by all foresters having to deal with this important seed problem.

## Pea Embryos in Sterile Culture

AN interesting contribution to our knowledge of the hormonization of seeds by growing dissected-out pea embryos in sterile culture has recently been made by W. Kruyt (*Proc. Koninkl. Nederlandse Akad. van Wetensch.*, Ser. C., LV, 4, 503; 1952). The peas were sterilized externally and the embryos removed with or without the attached cotyledons and grown in a sterile culture medium. Various pre-soaking treatments, for example, with and without growth-regulating substances, were investigated, and also the effects of factors in the culture medium and of leaving larger or smaller amounts of cotyledon attached to the growing embryo. It was found that the ratio of the amount of reserve material (in the cotyledons) to the size of the embryo has an important effect on development, that is, nutrition affects the morphogenetic development, the growth of root and sprout being stronger in proportion to the amount of cotyledon tissue left on the embryo. No development of leaves takes place in the dark, and, even in the light, embryos from which the cotyledons have been removed scarcely form leaves: leaf development, in fact, is in proportion to the amount of cotyledon left on the embryo. The author also reports the liquefaction of agar gels, especially by embryos with attached cotyledons. The development of lateral roots is mainly dependent on the amount of cotyledon tissue present. In a considerable series of experiments the action of various growth substances was also examined, the conclusion being reached that the greater part of the action of a growth substance, administered by pre-soaking the seeds, takes place by way of the cotyledons.

## Life Insurance Medical Research Fund of Australia and New Zealand

THE Life Offices' Association for Australasia has established the Life Insurance Medical Research Fund of Australia and New Zealand to promote and assist scientific and medical research. For the present it is intended to use the resources of the Fund to stimulate and support research in the field of cardiovascular function and disease, and for this purpose the Fund is offering grants-in-aid and research fellowships. Grants-in-aid will be given to non-profit institutions with basic facilities and qualified personnel for medical research and will be used in support of specific programmes of research, both fundamental and clinical, under the direction of a particular investigator; the grants will be worth £1,000–3,000 a year (or more, in exceptional circumstances) for one to three years and are designed to cover all the financial requirements of a programme, except the salary of the head of the department or institute concerned. Research fellowships will be awarded to medical graduates, or those with equivalent scientific training, for full-time research, and will be divided into three categories: fellowships taken up in Australia and New Zealand, of £1,250–1,500 a year in value, which will be for one year (but renewable for further periods); travelling fellowships, of £1,500–2,000 a year in value plus travelling expenses, which will be for two years abroad, followed by a third year in an approved institution in Australia or New Zealand; and senior fellowships, which will be granted in special circumstances. Application forms (to be returned by March 31) and further information can be obtained from Dr. John H. Halliday, Medical Director, Life Insurance Medical Research Fund of Australia and New Zealand, 87 Pitt Street, Sydney, N.S.W.

## Book Service for Industrial Operatives

THE National Book League is seeking information regarding the availability and use made of works libraries, with the view of the eventual establishment of a consultative service to factories, as visualized in a report of its Books in Industry Committee in 1949. Factory managements or their libraries are being invited to supply details regarding the size of the technical library they maintain from their budgets, the number of general books thus maintained, and whether or not a works librarian is employed and the library regularly brought up to date and at what cost. Information regarding facilities invited from public libraries includes the accessibility of books to operatives and the extent to which the books are used. The service contemplated is for the man at the bench rather than for scientific or research staffs. Information should be sent to Mr. R. Lusty, chairman of the Books in Industry Committee, National Book League, 7 Albemarle Street, London, W.1.

## British Agricultural History Society: Meeting in Reading

A NEW Society, to be known as the British Agricultural History Society, has recently been formed, and it is hoped that, besides the academic backing which it already enjoys, it will receive the support of a wide circle, including both farmers and townsmen, for whom the history of British rural life is of real interest. The first general meeting of the Society will be held in the University of Reading during April 13, and all who are interested are welcome to attend. The conference will open at 10.30 a.m. with the adoption of the constitution of the Society, which has been drafted by the provisional committee elected at the inaugural meeting last September, and with the election of officers. Following this formal business, Sir James Scott Watson will read a paper on "The Scope of Agricultural History". In the afternoon, Sir Frank Stenton will read a paper on "The Manor in English History". Visits to the Museum of English Rural Life, Reading, will be arranged during the day. The registration fee for the conference is 3*s*., and should be sent to the secretary of the Society, Mr. J. W. Y. Higgs, Keeper of the Museum of English Rural Life, Shinfield Road, Reading, Berks, from whom all further information can be obtained.

### Eighth International Congress of the International Society for Cell Biology

The date of the eighth international congress of the International Society for Cell Biology (Cytology Congress) has been changed from this year to 1954. It will be held in Leyden during September 1–7, under the presidency of Prof. E. Newton Harvey, of Princeton University, with Prof. P. J. Gaillard, of the Laboratory for Experimental Histology, University of Leyden, as secretary. Correspondence concerning the Congress should be addressed to Dr. W. H. K. Karstens, Botanical Laboratory, State University, Nonnensteeg 3, Leyden. Full members of the Society and candidates for membership approved by the International Committee are automatically entitled to attend the Congress, and to introduce two guests. Non-members are admitted as space permits, after provision has been made for members and their guests. Any member of the Society may nominate a new member from "those who have made outstanding contributions to cell biology over a period of years". The nominations, with a statement of qualifications and a list of the nominee's publications, should be sent to the secretary of the Society, Prof. J. F. Danielli, Zoology Department, King's College, London, W.C.2.

### *Endeavour* Prizes for Science Essays

In order to stimulate younger scientific workers to take an interest in the work of the British Association for the Advancement of Science and to raise the literary standard of scientific writing, Imperial Chemical Industries, Ltd., publishers of *Endeavour*, are offering a number of prizes for an essay, not exceeding four thousand words, on one of the following subjects: radio-astronomy; colour and chemistry; biology in world affairs; science and safety in transport; science and art; scientific contributions to medicine; scientific societies and their role; and power and civilization. Competitors must be less than twenty-five years of age and must send in their essays by June 1. The prizes will be 50, 25 and 15 guineas, respectively, with two special awards of 5 guineas for competitors less than eighteen, and in addition prize-winners will have their expenses paid for attendance at the British Association meeting to be held in Liverpool during September 2–9. Further details of these awards, which are known as *Endeavour* prizes, can be obtained from the Assistant Secretary, British Association for the Advancement of Science, Burlington House, Piccadilly, London, W.1.

### University of Leeds

Donations have been made to the University of Leeds as follows: £2,500 from the Cement and Concrete Association to the Department of Civil Engineering towards the cost of a universal testing machine; £1,100 from Bolton Leathers, Ltd., to the Department of Leather Industries, for the Boltonia Fellowship for 1952–53 and 1953–54; a gravity-feed stoker, valued at £1,085, from Crosthwaite Furnaces, and Scriven Machine Tools, Ltd., Leeds; and a grant of £500 a year (for one year in the first instance), with provision for superannuation purposes for half-time assistance and with up to £1,000 a year for expenses, from the Medical Research Council, to the Department of Experimental Pathology and Cancer Research, for work on the carcinogenic action of mineral oils.

### Colonial Service: Recent Appointments

The following appointments have recently been made in the Colonial Service: E. W. Momber (principal agricultural officer, Nigeria), assistant director of agriculture, Northern Region, Nigeria; B. E. V. Parham (senior agricultural officer, Fiji), deputy director of agriculture, Fiji; A. M. Anderson (fisheries officer, North Borneo), fisheries officer, Uganda; M. P. Benjamin (assistant agricultural superintendent, British Guiana), agricultural officer, Jamaica; J. O. Jaine (land ranger, Tanganyika), senior land ranger, Tanganyika; I. G. Lumsden (assistant conservator of forests, Northern Rhodesia), assistant conservator of forests, Nigeria; G. H. Rulf (assistant director of grain storage, Tanganyika), director of grain storage, Tanganyika; G. G. Rushby (senior game ranger, Tanganyika), deputy game warden, Tanganyika; E. H. Jones, agricultural officer (economist), Uganda; C. A. Waldron, agricultural officer, Tanganyika; H. I. Williams, bacteriologist, Federation of Malaya; A. Rogerson, scientific officer, East Africa High Commission; D. Bates, agricultural survey (cocoa) officer, Gold Coast; J. Forsyth, entomologist, Gold Coast; I. A. S. Gibson, mycologist, Forestry Department, Kenya; I. A. Hoffe, veterinary officer, Federation of Malaya; G. S. Scott, provincial tsetse officer, Tanganyika; W. E. Webb, senior scientific officer, forest entomologist, Timber Pest Research Unit, Gold Coast; T. W. W. Wood, assistant conservator of forests, Sarawak.

### Announcements

Two Ramsay Memorial Fellowships, worth £400 a year plus a grant for expenses not exceeding £100 a year, are being offered for chemical research; they will normally be tenable for two years. One of the Fellowships will be limited to candidates educated in Glasgow. Further information can be obtained from the Joint Honorary Secretaries, Ramsay Memorial Fellowships Trust, University College, Gower Street, London, W.C.1, to whom application forms must be sent not later than April 17.

The Ministry of Education is arranging a short course in chemistry for teachers from technical colleges, to be held in the Municipal Technical College, Coventry, during July 15–24. The instruction will deal with modern chemical techniques relating to chromatography and to semi-micro-analysis, and will consist of lectures and practical laboratory work. The course will be residential, but local teachers may be accepted as day students; the total charge for board and lodging is £8. Further information can be obtained from the Ministry of Education (Teachers Short Courses), 36–38 Berkeley Square, London, W.1.

The British Columbia Research Council at the University of British Columbia, Vancouver, has announced the following new appointments: *Chemistry Division:* H. Friedeberg (formerly of the University of Birmingham), W. F. Gruber (University of Vienna), H. G. Khorana (University of Cambridge), J. F. Smith (Imperial College of Science and Technology, London) and J. D. H. Strickland (formerly with the Ministry of Supply in Great Britain); *Metallurgy Division:* I. D. G. Berwick (University of Cambridge), J. G. Parr (University of Liverpool) and J. E. Srawley (formerly with the British Cast Iron Research Association).

# SOME SOCIAL AND PSYCHOLOGICAL PROBLEMS OF AGEING

THE programme of the British Association meeting last year in Belfast included a session by Section J (Psychology) on the problems of ageing. Mrs. M. Gilmore was in the chair. In the opening paper, which was a review of the problems of ageing in relation to medical science, read by Dr. G. F. Adams, physician to the Geriatric Department of the City Hospital, Belfast, the reasons were considered why old age should present problems in modern times any more than in the past. There has been a progressive increase, both absolute and relative, in the proportion of old people in the population, this increase being the result of the decline in infant and young adult mortality produced by the medical and social advances that have been made possible by the application of the scientific method during the past century. As a result of this, more old people must be supported by a diminished proportion of wage earners. There is a corresponding increase in the numbers of elderly invalids to be cared for, who are suffering from the degenerative diseases of old age which medical treatment may ameliorate, but not cure. Meanwhile, the expense of medical treatment, especially hospital treatment, has risen enormously and continues to rise, and it has been suggested that the community is faced with a gloomy prospect of unlimited 'medicated survival' to be met by diminishing resources. Dr. Adams disagreed with this view. Pointing out that medicine has long evaded its responsibilities to the clinical and social medicine of old age, being preoccupied in other fields of research, he outlined the new approach being made to the medical care of the elderly through the clinical work of hospital geriatric departments and the influence of social medicine in surveys of the problems of ageing. Much success has already been achieved in the prevention of unnecessary invalidism among the elderly sick, and many elderly patients hitherto regarded as 'chronic invalids' have been restored to activity, reducing the burden of nursing and domestic care otherwise necessary for them. Dr. Adams concluded that estimates of future needs for the elderly sick should be based on the results of such work rather than on limits set by the out-dated system of social and medical care of the past.

The second paper was read by Miss S. R. Burstein, of the Wellcome Historical Medical Museum, who urged that the problems of many old people are essentially mental rather than matters of physical infirmity or disease. The problems of adolescence have been the subject of a great deal of careful psychological and social research; there is a need for similar research upon the emotional problems concerned with the transition from middle to old age and especially upon the ways in which the years of old age can be used. It should be recognized that old age is not something which comes suddenly—ageing is continuous from birth—and that it is fundamentally wrong to segregate old people as 'problem cases' away from the functioning life of the community.

Miss Burstein stressed that one of the difficulties for those doing research upon problems of old age is that they are usually younger, and that it is thus difficult for them to understand fully the outlook of the people with whom their research is concerned. She urged that discussion with old people individually or in small groups, if done with patience and respect, yields far more insight into their attitudes and needs than can methods such as questionnaire studies which are more immediately convenient to the research worker.

The traditional pattern in which the whole family, old and young, lived together under one roof has largely broken down, with the result that many old people are extremely lonely. A return to the traditional pattern is clearly impossible, and, even if it were, it might involve satisfying the needs of old people at an undue cost in terms of freedom and privacy for those younger. Intermediate solutions where, for example, old people live alone but close to younger relatives often work well. The point needs to be stressed, said Miss Burstein, that old people themselves must carry a large share of the responsibility for making such arrangements successful. Although they are often glad of the opportunity of leisure afforded by retirement, many of them are capable of useful work, and this applies not only to work at a job but also to help in the family as a functioning group.

Mrs. A. V. Hill, a member of the Advisory Council of the National Corporation for the Care of Old People, read the third paper, which was an account of some emotional changes observed in advanced old age—mainly between eighty and a hundred years. Although these emotional changes may accompany physical changes, the emotional needs of old people cannot be met by physical care alone. Little study has been made of old people's needs, and physical care without attention to emotional needs often constitutes actual cruelty. While certain main lines of emotional change can be observed, it should be emphasized that, on one hand, striking exceptions occur among very old people and that, on the other, changes can take place before any great old age in terms of years alone has been attained.

The behaviour of very old people can often be explained in terms of fear of death, or of illness or of change of environment. The will to live is as strong as ever, and fear of illness or accident may dominate the life of an old person. At the same time they may unconsciously feign illness in order to gain attention. Movement from one dwelling to another frequently produces a 'transference shock' with signs of mental and physical deterioration which can sometimes result in death. Usually, however, old people settle down in the new dwelling, although they may take some weeks to do so. This has been frequently noticed among new residents in old people's homes, and, when it seems likely to occur, the old people are persuaded not to cut adrift completely from their old haunts until they have come to know the new. Among other emotional attitudes, affection, friendship and concern for the opinions of others suffer a marked reduction. In the extreme, apathy and general indifference may appear, especially after long periods in bed. Interest in what immediately concerns oneself may increase: thus small treasures are hoarded, and interest in food may grow. At the same time, the gift of being able to "enjoy other people" often continues to the end of a very long life.

Mrs. Hill urged that, broadly speaking, bed is bad for old people unless absolutely necessary on account of severe illness or weakness. Where possible, old people should be provided with small convenient dwellings where they can live alone. The independence and the effort involved in living alone can, as an example in one housing trust has shown, help old people to remain young for their age. Old people's clubs can help to relieve any loneliness which may be involved, and so also can part-time employment. An important experiment in the employment of people between seventy and eighty years of age for two hours daily is being made in Finsbury.

It is to be emphasized that people do not "suffer from old age": they suffer from illness, unhappiness and loneliness, but not from old age as such. There seems to be an increasing tendency to resist and resent old age. Those old people who accept and understand its inevitability are emotionally in a much stronger position than others.

Dr. John A. Oliver, principal officer in the Ministry of Health and Local Government, Northern Ireland, read an address entitled "Thinking About Old Age", in which he gave an account of present-day social problems of the elderly, with some reflexions on social thought and social policy. He outlined the main features of the social problems of old age to-day—more people surviving into old age in a community distressed by a housing shortage and a dearth of domestic help; and a weakening sense of family responsibility towards their elderly relatives on the part of parents anxious to give their children the best possible chance in difficult circumstances. This decline in family responsibility is encouraged, perhaps, by the lack of any legal obligation to provide for elderly relatives and by the increasing State provision being made for them. Dr. Oliver considered that the progress in social work and social legislation made in the last ten years has been largely pragmatic and has been "achieved without any real preparation in fundamental thinking". The practical workers beset by immediate problems have tackled them empirically as they arose, and our new social legislation, as it applies to the problems of ageing, has been launched in a philosophical vacuum. A philosophy of the social work, the social policy and the social services which we are operating must be evolved from experience and thought. Both legal and moral duties are involved in family responsibility for the aged, and we must recognize the fact that the State cannot be committed to an unlimited liability for the care of old people. Moreover, the hopes and desires of the old people themselves must be considered; and, since home is the normal place for most of them to live and end their days in, social services designed to make it easier to look after elderly relatives at home should be augmented and their potential contribution to industry encouraged by suitable work under suitable conditions. Is progress henceforward to depend on individual enterprise, asked Dr. Oliver—"the effort of the old person, the effort of the relatives and the neighbours or on community services devised by the State"? He said that he believes that this choice between individualism and collectivism is the central philosophical problem in the so-called Welfare State. In conclusion, he suggested that the British Association might establish a new section devoted to social science, or social philosophy, so that "British science may demonstrate its concern for social well-being and spiritual values".

Mr. A. T. Welford, director of the Nuffield Research Unit into Problems of Ageing, spoke of changes of human performance with age which affect capacity for industrial work. He stressed that many such changes associated with old age begin early in middle age, so that problems of employment for older people are not concerned only with those over the normal retiring-age. At some jobs ability seems to be well maintained into old age, and for almost all jobs a few older people can be found who are able to put up a performance comparable with that of a young man. At other jobs difficulties of maintaining adequate performance appear as early as the late forties. Difficulties of taking up a new job may appear earlier still.

The main difficulties for older people appear to be of three types, the first being where the form or the pace of the action involved is rigidly determined so that any slowness leads to an error of omission which cannot be afterwards redeemed. When the task is more flexible and the speed under the operator's control, an older person is often capable of compensating for slowness by increased care and accuracy. As a result of these compensatory tendencies, difficulties for people in later middle age in industrial work may go undetected—people maintain performance under an increasing strain until a suitable opportunity occurs to move away. Such moves are sometimes made following an illness which would not in itself warrant a change of job. Detailed examination of performance shows that often, contrary to popular opinion, slowness even in a manipulative task is due not to any limit set by the sense organs or by the effectors, but by the central brain processes which integrate and interpret information and form action.

The second type of difficulty occurs where the task is in some way complicated or confusing. So long as the relation between signals and the action required in response to them is simple and straightforward, performance by older people differs relatively little from that of younger. When, however, the relation is indirect or where several pieces of information have to be put together before action is taken, many older people are at a severe disadvantage.

The third type of difficulty is that of learning new tasks. This is, of course, generally recognized. The nature of the difficulty is not, however, clear. To some extent it is due to the application to the new task of previous habits which are not appropriate. In some cases, however, it appears to be due to inability to modify an erroneous method built up during early stages of practice.

In studying changes of performance with age, concluded Mr. Welford, it is important that we should not be led astray either by generalizations or by particular exceptional individuals. The ability of older people to do a job will depend both on the detailed demands of the job and upon the particular abilities which each individual can bring to it. Rigid general policies about retirement cannot therefore be justified on grounds of ability. The appropriate retirement-age will differ for the majority from one job to another, and from one individual to another at any job.

G. F. Adams
A. T. Welford

# CARNEGIE INSTITUTION OF WASHINGTON

## ANNUAL REPORT FOR 1951–52

THE report of the president of the Carnegie Institution of Washington, Dr. Vannevar Bush, for the year ending June 30, 1952[*], reviews the progress of the Institution during the fifty years since its foundation and then briefly summarizes the research activities of the past year. The aim prescribed for the Institution was to "encourage, in the broadest and most liberal manner, investigation, research and discovery, and the application of knowledge to the improvement of mankind". In furtherance of this aim, the Institution has always devoted its main resources to fundamental research, which Dr. Bush distinguishes from applied research in terms of purpose rather than of method, and it has no thought of changing its policy. While he welcomes the growing realization in the United States that basic and applied science are two parts of one endeavour, and the consequent expansion of fundamental research with increased support from the Government, Dr. Bush believes that the Institution's primary responsibility remains to carry on fundamental scientific research with no initial view to its industrial application. Where, however, in its fundamental research, ideas and principles emerge that promise material advantage to society, it is proper for the Institution to explore some of the broader possibilities of application for human betterment.

In the main, the Institution has fulfilled its duty, in Dr. Bush's view, if it is diligent in making the results of its work generally known as promptly as possible. This preoccupation with fundamental research has simplified many of the Institution's problems and its relations with other bodies, as it has determined the policy in regard to patentable inventions which Dr. Bush outlines in some detail. He does not consider, however, that the absence in the United States of any effective organization for bringing the fruits of disinterested research to the point where they invite industrial development warrants the Institution plunging into the application of science. The Institution may sometimes, nevertheless, need to look ahead beyond its immediate programme of research and publication.

Dr. Bush justifies this policy by citing the part which the Institution has played, in collaboration with the National Research Corporation and the Stamford Research Institution, in exploring the practical aspects of the mass cultivation of algæ following the investigations on photosynthesis in its Department of Plant Biology which demonstrated the possibility of growing the green alga *Chlorella* so as to produce 56 per cent dry weight of protein. Other instances are also cited in the report of researches which have been conducted by the Institution during the past half-century so as to contribute to an understanding of the cosmos, the earth and its inhabitants, and which have later provided the basis of important developments or practical undertakings. They include early work in 1925 on pulsations and their echoes from the ionosphere, which was one of the pioneer researches in radar, investigations in the Geophysical Laboratory on low-expansion quartz glass, which led to the development of 'Pyrex' and similar glasses, and the basic study of the soda-lime – silica system in the same Laboratory, which contributed to a scientific understanding of the glass industry. Later, a modified formula for annealing 'Pyrex' glass in large castings was fundamental to the successful manufacture of the 200-in. 'Pyrex' mirror for the Hale telescope, and the Laboratory studies of the ternary system lime – alumina – silica contributed to the development of the Portland cement industry. The researches of the Department of Embryology form an important part in every text-book on human embryology published during the past decade, and the Soil Conservation Service of the United States Department of Agriculture has drawn extensively on the basic knowledge of the evolution of new plant species gained in the range-grass experiments of the Department of Plant Biology during the past decade.

Turning to current research activities, the report refers to the co-operation between, on one hand, W. Baade and R. L. Minkowski, of the Mount Wilson and Palomar Observatories, and, on the other, groups of radio observers in Australia and England which has led to the identification of the strongest radio source, Cassiopœia *A*, with a galactic emission nebula about five minutes of arc in diameter, and of the second strongest source, Cygnus *A*, with an extragalactic nebula the structural pattern of which Baade interprets as probably representing two nebulæ in collision. A twelfth satellite of Jupiter was discovered by S. B. Nicholson on September 28, 1951. Investigations by E. H. Vertine, of the Department of Terrestrial Magnetism, afford an explanation of the major changes in the rate of the earth's rotation during the past fifty years, while, under a joint project with the Geophysical Laboratory, methods have been worked out for measuring the ages of virgin granite and of unaltered rocks found in close association with such massive igneous monoliths as, for example, the Sierra Nevada range. New methods and apparatus developed by the latter Laboratory have permitted rapid and easy measurements at pressures up to four thousand atmospheres and concomitant temperatures up to 800° C.

The Department of Plant Biology has continued its studies of the alga *Chlorella*, including the rate of photosynthesis with intermittent light over new ranges of intensities and flashing schedules, while urea has been found to be an excellent source of nitrogen for the growth of algæ. Some four hundred new hybrids have been produced between different species of blue grass, and a basic study of the genetic and ecological systems that characterize natural races and species is being advanced using the milfoils or yarrows. In the Department of Genetics investigations on mutability in *Escherichia coli* indicate that the rate of spontaneous mutation varies with temperature according to the van t'Hoff rule, and that an intimate relation exists between spontaneous mutation and cell division. It has been established that a typical bacterial virus consists of a membrane (chiefly protein) containing almost pure nucleic acid and that the function of the viral membrane in the infection of the bacterial cell begins with the anchoring of the viral particle to the cell wall and quickly ends with the injection of the viral nucleic acid into the cell. An enzyme capable of breaking down isolated, but not intact, intracellular deoxyribonucleic acid has been discovered in onion root tips, and studies on maize have indicated that at least two classes of functional genetic unit are carried by the chromosomes: one of them, the gene, is potentially capable of determining a particular course of cellular reactions; the other is associated with the control of this particular action.

---

[*] Report of the President of the Carnegie Institution of Washington for the Year ending June 30, 1952. By Dr. Vannevar Bush. Pp. 20 (Washington, D.C.: Carnegie Institution, 1952.)

In the Department of Embryology the discovery that there is extensive formation of neural-crest cells by the early embryonic eye (optic vesicle) throws light on the origin of the pigmented cells which appear early in the development of the eye. The development of the earliest human kidney rudiments has been thoroughly re-investigated, and further investigation of the physiology and biochemistry of uterine muscle has demonstrated that the 'staircase phenomenon', long known in heart muscle, occurs also in uterine muscle, and that the slope of the staircase is reversed by treatment with the corpus luteum hormone, progesterone. The discovery points to an essential role of potassium ions in uterine muscle contraction, and suggests that progesterone can modify the movement of potassium in and out of the muscle cell.

# OPTICAL SOCIETY OF AMERICA

## ANNUAL MEETING IN BOSTON

THE thirty-seventh annual meeting of the Optical Society of America was held during October 9–11, 1952, at Boston, Mass. Twenty-two invited papers covering spectroscopy, computational aids and atmospheric effects, in addition to other fields of science bordering on optics, were presented. The titles and abstracts of these papers and of the other contributed papers, together with a brief report of the proceedings of the meeting, are printed in the November issue of the Society's *Journal* (42, 868; 1952).

The invited papers include a discussion by N. Wiener on optics and the nature of spectra, a review of hyperfine structure investigations by F. Bitter, and a description of germanium phototransistors by J. N. Shive, of the Bell Telephone Laboratories. Various aspects of spectroscopy and radio astronomy are covered by communications from G. H. Harrison, R. Tousey, E. M. Purcell and others, including, in particular, one on multi-channel spectrometry by F. B. Follgett, of the University Observatories, Cambridge. In addition, a review of recent developments in infra-red spectroscopy is given by R. C. Lord.

Three papers are devoted to the subject of "Flying Saucers". It is pointed out by D. H. Menzel, of the Harvard College Observatory, that about one-fifth of the numerous reports received by the United States Air Forces did not admit of a simple explanation but that the majority of these, when examined carefully, could be explained as due to atmospheric physical phenomena, such as mirages, or reflexions from layers of fog or haze, or from ice-crystals. From a study of several hundred reports of unidentified aerial objects, it is concluded by A. Hynek, of the Ohio State University, that only one phenomenon, that of a hovering nocturnal light, is not readily explicable on an astronomical basis, and, finally, it is definitely stated by U. Liddel, of the Bendix Aviation Corporation, that no evidence exists for any phenomena not explicable by standard physical concepts.

The annual business meeting of the Society was held on the morning of October 10, and the annual banquet, preceded by a cocktail party given by the American Optical Company, during the evening. At the banquet, over which the Society's president, Brian O'Brien, presided, the Adolph Lomb Medal was presented to Dr. A. B. Meinel, of the Yerkes Observatory, and the Frederic Ives Medal to Dr. Ira S. Bowen, director of the Mount Wilson and Palomar Observatories. The after-dinner speaker was Dr. Harlow Shapley, of the Harvard College Observatory, who spoke on the subject of galaxies. The Adolph Lomb Medal is awarded to a promising scientist under thirty years of age, and the Frederic Ives Medal, which was established in 1928 by Herbert Ives in honour of his father, is for distinguished work in optics. Both medals are awarded every two years.

On receiving his medal, Dr. Bowen gave an address, entitled "Optical Problems at the Palomar Observatory", in which he described the support systems and the testing of the mirror and methods of increasing the effectiveness of the 200-in. Hale telescope, the main instrument at the Observatory. The mirror is a paraboloid of 660 in. focus; but, in addition, convex hyperboloids are provided which, when combined with the main mirror, give telephoto systems of which the focal lengths are 3,200 in. at the Cassegrain focus and 6,000 in. at the coudé focus. In addition to the mirror, the equipment of the Observatory includes three Schmidt cameras of 8, 18 and 48 in. apertures and operating at focal ratios of 1, 2 and 2·5, respectively. Dr. Bowen remarked that the cameras have remarkably fine definition over fields 9–20° in diameter and are efficient instruments for the rapid photography of large areas of the sky. Nearly all the equipment described has been in operation for from six months to three years, and the performance has come well up to expectation.

# BRITISH ASSOCIATION OF CHEMISTS

## HINCHLEY HOUSE

THE British Association of Chemists has recently acquired a freehold property, 14 Harley Street, London, W.1, for use as its headquarters. It was decided to name the premises 'Hinchley House' in memory of Prof. J. W. Hinchley, a founder member and the first president (1918–23). It was due to his influence and skill in directing its policy that the Association survived its first four difficult years. Prof. Hinchley was also instrumental in founding the Institution of Chemical Engineers, and his name will always be associated with chemical engineering, for many of the advances it has made in Great Britain are due to his conviction of its importance to industry and the necessity of making it a specialized branch of scientific study. The name of Prof. Hinchley had earlier been perpetuated through the annual award of the Association's Hinchley Medal, which is given for outstanding services to the profession of chemistry.

An opening ceremony was held at the new headquarters on February 27, when a number of members and guests, representing other bodies connected with the profession of chemistry, were present. Mr. F. Scholefield, president of the Association, in declaring the premises open, said that this function was indeed a red-letter day in the history of the British Association of Chemists, which thus became the first society of chemists to possess its own freehold property in London. The Association was formed in 1917 owing to the strong feeling among chemists in industry that there was no body having the prime function of looking after the economic interests of chemists. The Institute of Chemistry, as it was in those days, was a qualifying body, and it was outside its scope to look after such interests. After meetings in Birmingham, Manchester and London, the Association was formed.

Before long there was established, on the initiative of the London Section, a scheme whereby unemployment benefit was made available to members. The Unemployment Benefit Fund has been so well managed that to-day it is possible for the Association to pay as much as nine guineas per week to members temporarily unemployed. Although more than £20,000 has been paid out in benefit, there is to-day a balance of £52,000. It appeared to the House Committee, which included Mr. Norman Sheldon (chairman), Mr. C. S. Garland, Mr. G. T. Gurr and Mr. H. L. Howard, that it would be possible to invest some of that money to the advantage of the Fund and at the same time provide a worthy headquarters for the Association. Mr. Scholefield said that the greatest credit should be given to the House Committee, and that he would like to congratulate those who have been responsible for this really magnificent result. He then declared Hinchley House to be open.

After the ceremony, a tablet, inscribed with the names of the past-presidents and Hinchley medallists, was unveiled by Dr. Herbert Levinstein, who was president of the Association during 1923–24, immediately after Prof. Hinchley. This tablet was presented in memory of the late Mr. C. A. Wylie, president during 1951–52, by his family and friends.

Afterwards Dr. Levinstein gave this year's Hinchley Medal address entitled "Our Changing Chemical Industries : an Appraisement".

---

# SURVEY OF FOOD CONSUMPTION AND EXPENDITURE IN GREAT BRITAIN

IN Great Britain the War-Time Food Survey was almost entirely limited to urban working-class households, and, as the National Food Survey, it continued in the same form until the end of 1949. Since then, however, an attempt has been made to obtain a more representative sample, so that all classes and types of consumer are included. A recent report, issued by the Ministry of Food* is the first of an envisaged annual series, setting out full details of food consumption and expenditure by families throughout the country.

Records were obtained from 4,723 families, of which 70 per cent were "urban working class", 11 per cent were "other urban households", and 19 per cent were "rural". The first group provides data suitable for direct comparison with results obtained in the earlier surveys and permits long-term trends to be followed through. The new material, however, is subjected to much more detailed analysis in an attempt to bring out economic, dietetic or nutritional differences between one group and another. Families are divided according to "composition" and to "social class", and numerous tables are presented which show the effects of increasing numbers of children in the household. Seasonal variations are demonstrated, and also the varying ability of the different social groups to maintain their normal standards in the face of price increases (temporary or progressive).

As a social document this report is probably as valuable as any ; the data on which it is based are considerable and there is every sign of the greatest care having been taken to obtain a high degree of accuracy at every stage. Yet, as a contribution to nutritional knowledge in Great Britain it is disappointing ; it does not establish the caloric and nutrient levels at which these families were actually living, and yet that is the information which would be of most value.

The factual material, on the food consumption side, is confined to the amounts bought or obtained "free" during the survey week, together with appropriate additions or deductions according to "changes in stocks". The amounts discarded by the housewife in preparing the food for table have not been measured, nor has any record been made of the amount of edible material that was not actually eaten. It is a great weakness in this type of survey that, on both scores, arbitrary adjustments have to be made. The allowance for wastage of edible material made here is an overall ten per cent; but do we really throw away one loaf in every ten, every tenth bottle of milk, one-tenth of our butter, our sugar and all the other foodstuffs of which so many communities stand in the direst need ? If we do, it is time that the crime of so doing was brought home to us more strongly. It is good that a footnote promises that this matter is to be examined further ; certainly, it seems unlikely that all foods are wasted in the same proportion and to the same extent by all social groups.

Despite these deductions, however, it appears that intakes were more than adequate in practically all respects, although households with four or more children, or with both adolescents and children, were only marginal and were adversely affected by the lowering of the extraction rate of flour from 85 to 80 per cent in the middle of the year. There is, however, ample room for further errors in the estimates of requirements and in the arbitrary deductions made from the standards used, to allow for meals obtained outside the home. It is to be hoped that modifications will be introduced into the survey technique so that the necessary adjustments may, in future, be made on a more factual basis.

# WINTER CASCADING FROM AN OCEANIC ISLAND AND ITS BIOLOGICAL IMPLICATIONS

By BRIAN P. BODEN and ELIZABETH M. KAMPA
Bermuda Biological Station, Bermuda

THE circulation of Bermuda waters during the summer, and the possibility that this circulation acts as a mechanism for conserving insular plankton, have already been discussed[1]. Since that discussion presented only the summer picture, it became of interest to determine the winter circulation in order to understand the existence of an endemic plankton population.

It must be emphasized again that the marginal reefs around Bermuda are not at all continuous ;

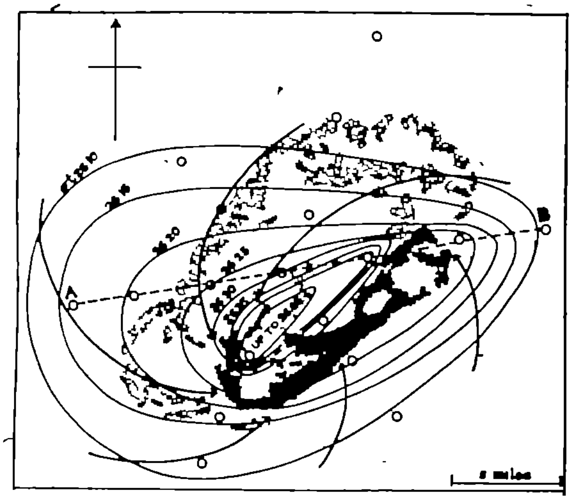

Fig. 1. Map of Bermuda and station plan. The islands are represented in solid black and the reefs are stippled. The stations are indicated by small circles. The intersections of $\sigma_t$ surfaces with the sea-surface are shown. The direction of the arrows is the probable direction of the water-movement. The section *AB* is shown in vertical profile in Fig. 2

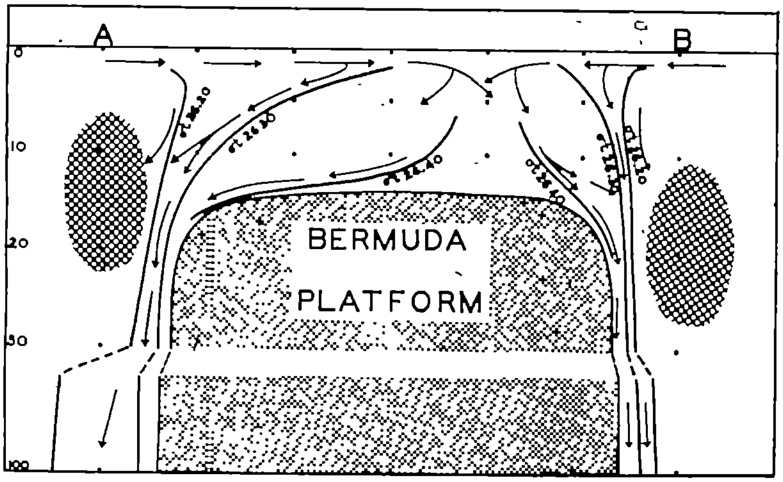

Fig. 2. Vertical density structure through section marked *AB* in Fig. 1. $\sigma_t$-Surfaces are shown and probable direction of flow is indicated by arrows. The cross-hatched areas represent density inversions in the water-column

they present no real barrier to free exchange between the lagoon and oceanic waters.

During a winter cruise, nineteen radially arranged hydrographic stations were occupied around the island and in the lagoon. Ekman reversing bottles and Negretti and Zambra reversing thermometers were used for obtaining water samples and temperatures at standard depths from the surface to 100 m. or to the bottom. Bathythermograms were made with both shallow and deep bathythermographs. The weather in Bermuda in late February frequently makes oceanographic work from a small, open boat rather hazardous, and for this reason it was considered desirable to complete as many stations as possible in as short a time as possible. Plankton sampling was therefore eliminated, making it possible to occupy enough stations to determine the hydrographic conditions.

The average surface salinity in the lagoon was 36·48 ‰, and at the oceanic stations it was 36·45 ‰. Surface temperatures in the lagoon averaged 18·60° C., while outside the lagoon the average was 19·11° C.

The intersections of $\sigma_t$ surfaces (equal density at zero pressure) with the surface of the sea are shown in Fig. 1. This density distribution must be associated with a cyclonic vortex. Both thermal and haline circulations exist and reinforce each other.

The vertical distribution of density along the section marked *AB* in Fig. 1 is shown in Fig. 2. The probable direction of water movement is indicated by the arrows. The surface water flows into the lagoon where (its specific gravity increased by cooling) it sinks and flows out along the lagoon floor and down the sides of the island. The cross-hatched areas at the edge of the platform represent density inversions in the water column, the water in the cross-hatched areas being heavier (by 0·02 $\sigma_t$-unit) than the water above it or immediately below it. This anomaly exists all around the island, probably because the momentum of the heavy water flowing over the edge of the platform is sufficient to carry some of it over the lighter water to the cross-hatched areas where mixing takes place. This vertical circulation is the type of local cascading over shallow banks discussed by Cooper and Vaux[2].

In general, then, the winter circulation can be described as a cyclonic, convergent movement about a sinking centre (as indicated by the arrows in both figures), and a certain amount of vertical mixing across the $\sigma_t$ surfaces takes place. This convergent movement and general cyclonic drift during winter are a complete reversal of the summer circulation, and have been noted in early Bermuda Biological Station reports (unpublished) as a result of drift-bottle surveys and of the inshore presence of oceanic plankton forms. In common with the summer circulation discussed previously, this circulation may be typical of the majority of islands in temperate latitudes.

The summer circulation about Bermuda has been shown to favour the survival of an endemic plankton population and of a benthos with planktonic larval stages[1]. With the exception of those forms which have dormant winter stages, enabling them to survive in local pockets until the return of favourable summer conditions, such an endemic insular plankton could not persist through an adverse winter circulation. The vertical circulation discussed here certainly does tend to carry the plankton down, probably to considerable depths, where it may be carried away from the island by the large-scale currents flowing past it. Singularly enough, the more feeble swimmers such as the larger medusæ, the powers of vertical migration of which are limited, do not appear in the plankton until the summer. The shallower summer circulation, which concentrates them around the island, tends to keep them also in the upper layers. This is doubly favourable, for most of these medusæ carry symbiotic algæ which would perish at depth.

The greater part of the zooplankton, however, migrates to the surface at some time during the day or night. It is thus returned to waters which are converging upon the island. [Aug. 11.

# RESONANCE RADIATION FROM HYDROGEN FLAMES CONTAINING ALKALI METALS

By C. G. JAMES and DR. T. M. SUGDEN
Department of Physical Chemistry, University of Cambridge

PREVIOUS workers[1,2] have shown that the intensity of the resonance radiation emitted by alkali metal atoms in flames (transition $nP_{3/2,1/2} \rightarrow nS_{1/2}$) varies linearly with concentration for small amounts, and with the square root of the concentration for large amounts, of the metal. This change of order depends on the self-absorption in the flame, which is in turn a function of the broadening of the lines by Doppler and collision effects. The present work demonstrates how these considerations may be applied to the problem of the formation of stable gaseous hydroxides in flame gases, and further to the elucidation of the collision diameters of the excited alkali atoms, using the results at low and at high concentrations respectively.

On the basis of the treatment of Mitchell and Zemansky[1], it can be shown that the measured intensity $I$ of the light emitted from a flame, of thickness $l$ cm. and temperature $T°$ C., in the form of resonance radiation from an added alkali metal is:

$$I = \frac{8\pi\alpha hc}{\lambda^3} \cdot \left(\exp - \frac{hc}{\lambda kT}\right) \int_0^\infty \{1 - (\exp - k_\nu l)\} d\nu, \quad (1)$$

where $\lambda$ is the wave-length of the centre of the line, and the integration is performed over the whole line with absorption coefficient $k_\nu$ at frequency $\nu$. The constant $\alpha$ depends on the measuring instrument only. At low concentrations the integral reduces to:

$$l \int_0^\infty k_\nu d\nu = \frac{\lambda^2}{8\pi} \cdot \frac{g_2}{g_1} \cdot \frac{Nl}{\tau} \equiv \frac{\pi e^2}{mc} \cdot Nfl, \quad (2)$$

where $\tau$ is the mean life of an excited atom, $f$ the '$f$ value' of the transition, $N$ the number/c.c. of alkali atoms in the ground state, and $g_2$ and $g_1$ the statistical weights of excited and ground states respectively.

Introducing the total absorption $A_G$, defined by Ladenburg and Reiche[3]:

$$A_G = 2\pi \int_0^\infty \{1 - (\exp - k_\nu l)\} d\nu, \quad (3)$$

equations (1) and (2) give rise to:

$$\frac{A_G}{\Delta\nu_D} = \frac{2\pi^2 e^2}{mc} \cdot \frac{Nfl}{\Delta\nu_D}, \quad (4)$$

where $\Delta\nu_D$, the Doppler broadening, has been introduced for reasons seen later. Plots of log $(A_G/\Delta\nu_D)$ against log $(Nfl/\Delta\nu_D)$ for the various metals should therefore coincide at low concentrations, and have unit slope.

Measurements of $I$ and hence $A_G$ have been made by adding fine sprays of alkali metal salts of known strength from an atomizer to the air-supply of a pre-mixed hydrogen/air flame, burned in a Méker-type burner with a surrounding flame of similar composition but without spray, so as to give a shield against self-reversal at the boundary, and observing the light emitted about 1 cm. above the small cones with a photocell. The light was chopped by a sector disk, which synchronized an amplifier so as to enhance selectively the photoelectric signal. Lines were isolated by Ilford spectrum filters and a dilute copper sulphate filter. Apart from a constant factor $\alpha'$, the measured intensities on a meter were converted by filter and photocell factors to absolute values. The results are shown in Fig. 1, plotting log $(A_G/\alpha'\Delta\nu_D)$ against log $(Cfl/\Delta\nu_D)$, where $C$ is the concentration of salt solution (chloride) in the atomizer. Complete dissociation of the salt is expected at the temperatures and concentrations used in the flame.

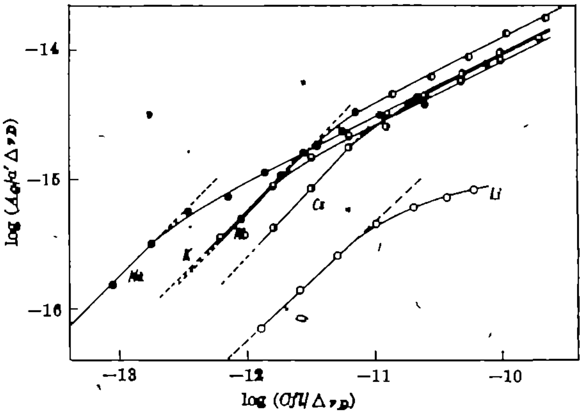

Fig. 1. Variation of 'total absorption' with concentration for various alkali metals in hydrogen/air flames

The results have the general form described above, but do not coincide, as equation (4) requires, at low concentration. It is suggested that this divergence arises from formation of gaseous hydroxide molecules, by reaction with the free hydroxyl radicals of the flame gases:

$$AOH \rightleftharpoons A + OH; \; K = \frac{[A]\,[OH]}{[AOH]} \equiv \frac{[OH]}{\varphi}. \quad (5)$$

[OH] is constant, being buffered by the flame gases, and is approximately $10^{-8}$ atmospheres, while the alkali metal concentration is in the range $10^{-4}$–$10^{-8}$ atmospheres. These results support previous work by Smith and Sugden[4] on ionization in flames and on the theoretical values of the equilibrium constant $K$ of equation (5): in particular, that work suggested that gaseous NaOH was negligible in these flames, but that the relative stability of the other hydroxides was LiOH > CsOH > RbOH > KOH, corresponding with the conclusion which may be drawn from Fig. 1, namely, that the concentration $C$ is not a measure of $N$, but of $(1 + \varphi)N$, and that this factor $(1 + \varphi)$ is responsible for the non-coincidence of the lower portions of the plots of Fig. 1. The values of $\varphi$ derived from Fig. 1 are somewhat higher than those from the ionization work.

If this hypothesis be correct, then the relative corrections from $C$ to $N$ may be made by shifting the curves along the abscissa so that the dilute portions coincide with that of the sodium (since its hydroxide may be neglected). The remaining (square-root) portions of the curves may now be compared.

The general expression for the absorption coefficient $k_\nu$ is very complicated, but we have shown that the following simple form is valid in the square-root portions of our plots:

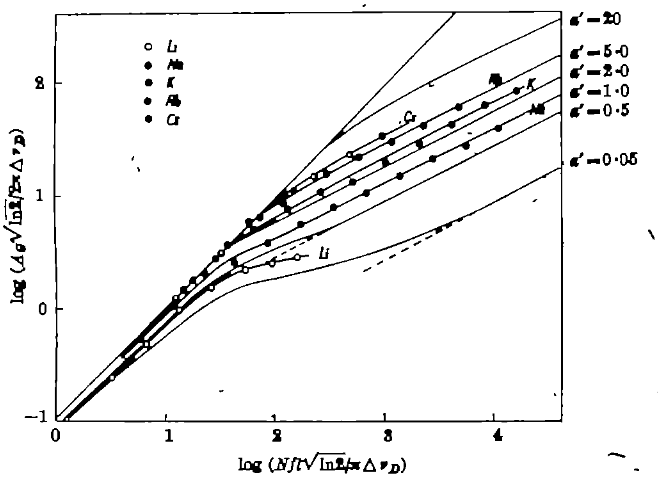

Fig. 2. Plots of 'total absorption' for determination of collision diameters

$$k_\nu = k_0\left(\frac{a'}{\omega^2\sqrt{\pi}}\right), \tag{6}$$

where $\omega = \dfrac{2(\nu-\nu_0)\sqrt{\ln 2}}{\Delta\nu_D}$, $a' = \dfrac{\Delta\nu_N + \Delta\nu_L}{\Delta\nu_D}\cdot\sqrt{\ln 2}$

and $$k_0 = \frac{2}{\Delta\nu_D}\sqrt{\frac{\ln 2}{\pi}}\cdot\frac{\pi e^2}{mc}\cdot Nf,$$

in which $$\Delta\nu_D = \frac{2}{\lambda}\sqrt{\frac{2RT\ln 2}{M_1}},$$

$\nu_0$ is the frequency of the centre of the line, $\Delta\nu_N$ is the (negligible) natural broadening and $\Delta\nu_L$ the Lorentz collisional broadening

$$\left(= \frac{2}{\pi}\,\sigma_L{}^2\,N_2\sqrt{2\pi RT\left(\frac{1}{M_1}+\frac{1}{M_2}\right)}\right),$$

where $M_1$ is the atomic weight of the alkali metal, $M_2$ the molecular weight of the colliding species of population $N_2$/c.c., and $\sigma_L$ the collisional diameter of the excited alkali atom in the flame. This leads to equation (7):

$$\frac{A_G}{\Delta\nu_D} = 2\pi\sqrt{\frac{2\pi e^2}{mc\sqrt{\ln 2}}}\cdot\sqrt{a'}\cdot\sqrt{\frac{Nfl}{\Delta\nu_D}}, \tag{7}$$

with expected variation with $\sqrt{N}$. The family of curves of log $(A_G/\Delta\nu_D)$ against log $\left(\dfrac{Nfl}{\Delta\nu_D}\cdot\dfrac{\sqrt{\ln 2}}{\pi}\right)$ with various $a'$, as depicted by van der Held[5], will be absolute. The theoretical forms for various $a'$ are shown in Fig. 2 (thin lines). To accord fairly closely with the recent work of Sobolev, Mezhericher and Rodin[2], and the results of Schutz[6], the experimental curve of Fig. 1 for sodium has been superposed on $a' = 1{\cdot}0$, and the hydroxide correction above made to bring the others into their correct relative positions (thick lines with points).

| Metal | $a'$ | $\sigma_L{}^2 \times 10^{16}$ cm.$^2$ |
|---|---|---|
| Lithium | 0·3 | 22 |
| Sodium | 1·0 | 68 |
| Potassium | 2·8 | 125 |
| Rubidium | 5·3 | 180 |
| Caesium | 6·3 | 164 |

The ordinates of the square-root parts give values of $a'$ from which the collision diameter $\sigma_L$ can be deduced, assuming the colliding species to be mainly nitrogen. These are given in the table.

The last column is of the expected order, with the exception of cæsium, which is rather anomalous. Further support is given by the results for lithium, which are beginning to show the characteristic flattening of very low $a'$ in Fig. 2.

Since van der Held's curves are absolute, these results can be used to give the absolute concentration $N$ in the flame. Thus 1$N$ sodium solution in this case gives, from Figs. 1 and 2, $2{\cdot}3 \times 10^{14}$ atoms/c.c. of flame, in the ground-state, corresponding with a partial pressure of $7 \times 10^{-5}$ atmosphere.

This type of study can provide, therefore, information which is useful in practical flame photometry, in measuring concentrations and therefore in studying equilibria at high temperatures, and in the study of collisional phenomena connected with radiation.

# STRUCTURE OF STARCH

## By Prof. R. H. HOPKINS

British School of Malting and Brewing and Department of Applied Biochemistry, University of Birmingham

IN a recent communication, Blom and Schwarz[1] conclude that the molecules of starch contain, in addition to the generally accepted α-1,4- and α-1,6-glucopyranosidic linkages, an additional type of glucosidic link. The type which is considered by them to fit the facts is the α-1,5-link connecting a glucopyranose to a glucofuranose residue, this occurring alternately with the 1,4-link. In other words, the part of starch which is susceptible to the action of β-amylase is composed of unbranched chains consisting of alternate pyranose and furanose rings. The authors do not develop their hypothesis, but merely indicate how, under it, β-amylase would function. The experimental evidence furnished is, briefly, that on hydrolysis by acids the fall in optical rotation is abnormally small in the first stages of fission, rising considerably as the reaction proceeds. The existence of an additional type of link is indicated, and this leads straight to the above conclusion. A re-examination of the evidence for the accepted structure is called for, attention being confined to the unbranched part of starch, for example, amylose.

The hypothesis of alternate pyranose and furanose links has its attractions for the enzyme chemist. For example, the action of β-amylase, which, starting from the non-reducing end of a chain, by-passes the first link but breaks the second one although this is identical with the first one, and produces β-maltose from an α-link, presents features which are unusual in enzyme action. On their hypothesis, although the authors do not state so, it is necessary to assume that the first two glucose residues from the non-reducing end are in the pyranose form linked as in maltose, and that a 1,5-link to furanose follows. We may assume that hydrolysis by enzymes proceeds by such mechanism as this:

β-*Amylase* breaks the 1,5-link liberating α-maltose. It must be presumed also to open the furanose ring of the adjoining group, leaving it in an open-chain form, from which a new pyranose ring is formed, thus accounting for the mutarotation in the upward sense. The estimated rise in rotation would be about sufficient to mask the downward change in the liberated α-maltose and leave a resultant upward change equivalent to that observed by Kuhn[2]. Two pyranose residues are now at the end of the chain in position for the next fission by the enzyme.

α-*Amylase* splits 1,5-links at various parts of the chain, similarly opening the adjoining furanose residue but catalysing also its closure to the pyranose ring. This enzyme must be assumed to combine functions of fission with those of the 'mutarotase' recently described[3] which catalyses mutarotation of glucose. Indeed, the opening of the furanose ring might facilitate the accompanying fission at its fifth carbon atom. Thus α-amylase splits off α-mutarotating fission products; the upward mutarotation due to the furanose–pyranose change is not observed, it being as rapid as the enzyme action.

*Hydrogen ions* function to the same effect as α-amylase, attacking the 1,5-links much more readily than the 1,4-links. The high (for example, 80 per cent) yield of acetobromomaltose from starch by the action of acetyl bromide[4] would require the same mechanism for the hydrolysis.

Calculation of the specific rotatory power of starch (in water) on the basis of that of the α-glucosidic link and residue in maltose leads to higher values[5], + 229°, than those observed (200°). On the hypothesis put forward, it would approximate to the latter.

The adverse side of the picture must be presented. Including the usual arguments[6,7] in favour of the α-glucopyranoside chain there are the following:

(1) Furanose forms are rare in naturally occurring glucose compounds.

(2) The rates of hydrolysis of furanosides by acids, for example, ethyl glucofuranosides, are some 50–200 times faster[8] than those of the corresponding pyranosides. To answer this it would be necessary to assume that the furanoside group in the middle of a chain, with its fifth carbon atom anchored to the chain beyond, could be quite stable; and, in fact, that its 1,4-glucosidic link is not attacked by the hydrogen ion as readily as the pyranosidic 1,5-link, while the latter in its turn is hydrolysed more slowly than the link in maltose[5,8]. But the exposure of a furanose residue by fission of the 1,5-link adjoining it should leave it susceptible to rapid acid hydrolysis, as with the ethyl glucofuranosides, so that each 1,5-fission should be, in effect, accompanied by an α-1,4-fission. The latter would cause such a fall in optical rotation as to mask the small fall caused by the 1,5-fission, and no maltose would be formed. Blom and Schwarz do not consider that such a furanoside is necessarily unstable and furnish argument in support of their view.

(3) α-Amylase splits amylose to produce not only maltose, as required by the hypothesis, but also appreciable quantities of glucose and maltotriose. This requires the enzyme to attack two very different α-glucosidic links and at different rates. Alternatively, the mutarotase function postulated above could, if slowly operated, give opportunities for the open chain to break away at its reducing end. This would be assumed to happen in a certain proportion of the cases, depending on the relative rates of exercise of these two functions. The different types of α-amylase might vary among themselves in this respect. (Incidentally, any lag in this liberation of glucose could well account for the anomaly reported by Kuhn[2], a sudden rise in rotation during the action of pancreatic amylase.) The removal of glucose in such a way would give rise to a dextrin with an odd number of glucose residues in it, ultimately yielding maltotriose. But this maltotriose would contain a furanose residue in the middle position.

(4) The structure of maltotriose has recently[9] been established as that of three glucopyranose units. It is true that the material investigated might have originated from a portion of the starch (amylopectin) near the branch-points to which the pyranose–furanose structure need not apply. However, maltotriose is definitely formed from amylose by α-amylases[10,11], and appears in some cases in the comparative absence of glucose.

(5) The mechanism of action of phosphorylase[12] and amylo-glucosidase[13] in forming respectively glucose-1-phosphate and glucose from a chain with alternate pyranose and furanose residues is difficult to work out, and, as with α-amylase, requires specificity for two different links. On the other hand, the need for a primer of three or four groups in length to initiate synthesis of phosphorylase[14] could be well accounted for.

Altogether, it must be concluded that the hypothesis put forward by Blom and Schwarz creates more difficulties than it clears up. Nevertheless, their experimental results call for explanation. These and the discrepancy in the $[\alpha]_D$ of starch, referred to above, are due to the same cause, with which the upward mutarotation of β-amylase fission products may also be associated. Explanation may well be found along the line that the α-glucosidic residues in the middle of a chain are pyranose but nevertheless possess very decidedly lower optical rotatory power than in maltose. Calculation of the value of $[\alpha]_D$ of maltotriose from the values of α-glucose and maltose leads to + 168° for the solution in water at equilibrium. If maltotriose derived from amylose, possessing $[\alpha]_D$ + 158° as found in these laboratories (cf. French *et al.*[15]), can be shown to be composed solely of α-glucopyranose units, as Wolfrom has done for what appears to be the same compound, this would go far to account for the $[\alpha]_D$ of starch, since the value 158° is in good agreement with the Freudenberg rule. # LETTERS TO THE EDITORS

*The Editors do not hold themselves responsible for opinions expressed by their correspondents. No notice is taken of anonymous communications*

## A New Blood-Group Antibody, Anti-$Jk^b$

THE human blood-group system called *Kidd* was discovered in 1951 by Allen, Diamond and Niedziela[1], who found an antibody, anti-$Jk^a$, which distinguished two phenotypes, $Jk(a+)$ and $Jk(a-)$. Family investigations[2] showed that the antigen $Jk^a$ is inherited and that the gene $Jk^a$ is capable of expressing itself in single and in double dose; the existence of an allelomorphic gene $Jk^b$ was assumed. In tests on 390 unrelated persons[2], the phenotype frequencies were $Jk(a+)$ 76·92 per cent and $Jk(a-)$ 23·08 per cent, from which the following gene and genotype frequencies were calculated:

| Genes | | Genotypes | |
|---|---|---|---|
| $Jk^a$ | 0·5196 | $Jk^aJk^a$ | 0·2700 |
| $Jk^b$ | 0·4804 | $Jk^aJk^b$ | 0·4992 |
| | | $Jk^bJk^b$ | 0·2308 |

The finding of the antibody corresponding to the antigen, and gene, $Jk^b$ is here reported. It has been found in the serum of Mrs. W. Mrs. W. gave birth to full-term healthy infants in 1937 and 1940 and had miscarriages in 1944 and 1951. There is no history of hæmolytic disease of the newborn. She was transfused with blood after the second and again after the fourth delivery. The latter transfusion had to be stopped owing to a rigor, and because of this her serum was examined.

The blood groups of Mrs. W. are *O*, *MsMs*, *P*+, *cDE/cde*, $Lu(a-)$, *K*−, $Le(a-b+)$, $Fy(a-)$, $Jk(a+)$. Her serum contains anti-$Fy^a$ as well as anti-$Jk^b$. The more powerful anti-$Fy^a$ was recognized first; the presence of anti-$Jk^b$ was suspected from the results of tests on $Fy(a-)$ red cells. The anti-$Fy^a$ was removed by absorption, leaving in the serum anti-$Jk^b$ alone. The cells used for this absorption were from a person known to be homozygous $Fy^aFy^a$ and thought, from previous dosage work with anti-$Jk^a$ sera, to be homozygous $Jk^aJk^a$.

That the antibody left in the absorbed serum is indeed anti-$Jk^b$ is shown as follows.

(1) Ninety-eight members of the staff of the Lister Institute have been tested, with the following results:

| | | $Jk(a+)$ | $Jk(a-)$ |
|---|---|---|---|
| Mrs. W.'s serum absorbed | + | 44 | 19 |
| | − | 35 | 0 |

If the new antibody were not related to the *Kidd* groups the 'exact' probability of getting such a result would be only 1 in 14,129. There is no association with any of the other blood-group antigens, with sex or with the ability to taste phenyl thio-carbamide.

(2) All 19 $Jk(a-)$, that is, $Jk^bJk^b$, persons so far tested are positive, and so are all of 22 persons known from family studies to be heterozygous $Jk^aJk^b$. (Seven of these heterozygotes are in the Lister 98; a further 15 were selected and do not appear in the 2 × 2 table.) If the new antibody were not associated with $Jk^b$ the chance that all 41 persons should be positive is but one in many thousands.

(3) The positive reactions of the new antibody are, on the average, a little stronger with $Jk(a-)$ than with $Jk(a+)$ red cells.

The new antibody in the serum of Mrs. W. is therefore anti-$Jk^b$. Of the 79 $Jk(a+)$ persons in the 2 × 2 table it can be calculated that about 51 should be $Jk^aJk^b$, and therefore positive with anti-$Jk^b$, while 28 should be $Jk^aJk^a$ and therefore negative; in fact, 44 were positive and 35 negative, which is not a significant departure from expectation ($\chi^2 = 2 \cdot 9$ for 1 degree of freedom).

The presence of anti-$Jk^b$ in this serum was first demonstrated by the indirect anti-globulin method, but was not detectable by the trypsin or other tests. The reactions were weak. It was then found, however, that an indirect anti-globulin test on trypsinized cells, a combination of tests recommended by Unger[3], gave very clear results.

The existence of the antibody anti-$Jk^b$ promotes the *Kidd* system to fourth place in the order of 'usefulness'[4] of the nine blood-group systems. 'Usefulness' is a measure, suggested by Fisher, of the potential value of the systems in human genetics and in problems of identity, parentage and paternity.

We are grateful to Mr. Norman White and Dr. Martin Hynes, of the Royal Northern Hospital, Holloway, for their co-operation; we also acknowledge, once again, the kindness of our long-suffering colleagues at the Lister Institute in giving innumerable samples of blood.

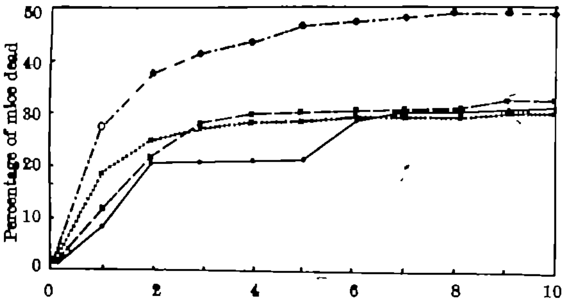
## Effect of Hyaluronidase on the Mortality from Experimental Burns

IN treating secondary shock, the intravenous route of fluid administration may not be possible under certain conditions, as, for example, in small infants or in the event of a catastrophe when sufficient trained personnel are not available. In lieu of the intravenous route, the interstitial administration of fluids containing hyaluronidase to assist assimilation has been used clinically in recent years[1]. With the addition of this enzyme to break down hyaluronic acid, the fluid spreads more rapidly throughout the connective tissue, thereby entering the capillaries more rapidly, with a consequent increase in the effectiveness of the shock therapy.

If hyaluronidase is to be used in hypodermoclysis, however, it is important to establish that it exhibits no adverse effects otherwise on the shocked individual as, for example, in burns. For this reason, the effect of hyaluronidase on burned, shock-treated animals was studied experimentally.



Influence of hyaluronidase on mortality of mice after an experimental burn.
○ —·— — ○, 'Hydase' applied at burn site (80 mice); × ...... ×, heated 'Hydase' (control) at burn site (80 mice); ■ — — — ■, 'Hydase' injected distally (60 mice); ● —— ●, heated 'Hydase' (control) injected distally (60 mice)

Adult, male, Connaught strain white mice deeply anæsthetized with 'Nembutal' were subjected to a standard burn produced over the dorsum by immersing a constant fraction (one-third) of their body weight in water at 70° C. for 20 sec. The mice were afterwards treated for shock with 1 c.c. of physiological saline administered intraperitoneally in two doses: 0·5 c.c. immediately after the burn, the other 0·5 c.c. two hours later.

Three sets of paired experiments were carried out, one in which the hyaluronidase (Wyeth 'Hydase') was added to the saline given intraperitoneally, one in which the hyaluronidase was injected subcutaneously (0·1 c.c.) in an area remote from the burn, and a third in which the hyaluronidase was applied locally to the burned area in 0·25 c.c. saline. The latter two studies were carried out in paired experiments in which the control mice received equal quantities of hyaluronidase which had been inactivated by heating at 100° C. for 15 min. The results are shown in the accompanying table. In addition, the graph illustrates the time-course of the mortality of mice treated locally to the burn and subcutaneously distally with 50 turbidity reducing units of hyaluronidase and of the controls similarly treated with the inactivated enzyme.

From these observations, it is seen that the mortality of the burned mice treated with hyaluronidase intraperitoneally or subcutaneously distal to the burn is essentially the same as that of the controls. The addition of even relatively large doses of hyaluronidase by these routes, therefore, has not otherwise prejudiced the chances of survival of the burned animals. Conversely, however, the local application of hyaluronidase directly to the burned surface has definitely increased the mortality in the burned animals. With 50 turbidity reducing units of enzyme, this increase is significant at the $P = 0{\cdot}03$ level. From the limited series of animals treated marginally with 15 units, it seems that an increased mortality is also produced with smaller doses of hyaluronidase applied locally in the burned area.

Effect of Hyaluronidase on the Mortality of Burned Mice

| Dose of hyaluronidase or inactivated hyaluronidase | Mode of administration | Total No. of mice burned | No. dead in 10 days | Per cent dead |
|---|---|---|---|---|
| 1·5 TRU* enzyme | Subcutaneously in 0·1 c.c. saline distal to burn | 40 | 12 | 30 |
| 1·5 TRU inactivated | | 40 | 11 | 28 |
| 15 TRU enzyme | | 39 | 10 | 26 |
| 15 TRU inactivated | | 38 | 11 | 29 |
| 50 TRU enzyme | | 60 | 20 | 33 |
| 50 TRU inactivated | | 60 | 19 | 32 |
| 0 TRU enzyme | Intraperitoneally (in saline) | 26 | 11 | 42 |
| 0·02 TRU ,, | | 26 | 10 | 38 |
| 0·5 TRU ,, | | 26 | 8 | 31 |
| 12·5 TRU ,, | | 26 | 8 | 31 |
| Saline | Subcutaneously into margin of burn (0·1 c.c.) | 20 | 10 | 50 |
| 15 TRU enzyme | | 20 | 13 | 65 |
| 50 TRU inactivated | Applied to burn surface in 0·25 c.c. saline | 80 | 25 | 32 |
| 50 TRU enzyme | | 80 | 40 | 50 |

* TRU = turbidity reducing units.

The increase in mortality observed when hyaluronidase was applied to the burned skin with the consequent breakdown of the hyaluronic acid in the wound may result either from an increased absorption of toxic material from the burn or from increased loss of fluid into the wound or from a combination of these factors. At post-mortem the burns treated locally with hyaluronidase seemed to be more œdematous than those similarly treated with the inactivated enzyme. Sections of the burned skin treated with hyaluronidase or with inactivated hyaluronidase locally were therefore examined for œdema. The mean full-skin thickness from the burn in seven sections of mice treated with hyaluronidase was indeed found to be slightly but measurably greater when compared with seven sections from mice treated with the inactivated hyaluronidase. The areas were measured quantitatively by projection. This small sampling thus tends to confirm objectively the post-mortem impression.

From this experimental work in animals, it is concluded that tests to establish the safety of using hyaluronidase in hypodermoclysis in the treatment of burned patients are probably justified clinically in areas away from the burn, since no adverse effects could be shown with relatively large doses of hyaluronidase, provided the enzyme was given subcutaneously distal to the burned area or intraperitoneally.

This work was carried out under contract between the Defence Research Board of Canada and the Hospital for Sick Children, Toronto.

## Lipoids and Cholesterol in New-born Rats

The organism of new-born rats is subjected to many post-natal changes. Certain organs, and probably all the body, will achieve in stages the functions which they have in the adult animals. It has been stated that the hypophysis develops its complete functions after birth. Heller[1] found in the hypophysis of new-born rats ten times less adiuretine than in adults. Schreiber[2] noticed the embryological, anatomical and physiological relation of the neurohypophysis, hypothalamus and visual organs, and was led to look for correlation with the evolution of the water metabolism of new-born rats as the expression of the action of the diencephalo-pituitary system and the functional evolution of the eye. He observed that, in rats just beginning to see, the dry matter is increasing and chlorides decreasing with

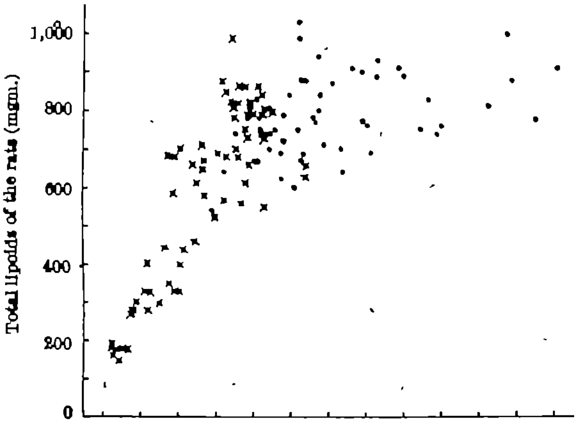

Fig. 1

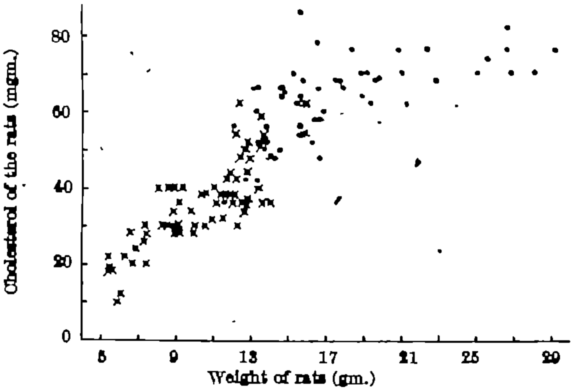

Fig. 2

Fig. 1. Relation of total lipoids to the body-weight of new-born rats. ×, Rats which could not see; O, rats which could see

Fig. 2. Relation of cholesterol to the body-weight of new-born rats. ×, Rats which could not see; O, rats which could see

the growth in weight. The decrease is quicker in rats before their eyes are open. He explains his results as the completion of evolution of the neurohypophysis at the time when the rat is just beginning to see.

In the present work, the content of total lipoids and cholesterol in albino rats was found from birth to the age of twenty days, with particular regard to that time when they begin to see.

Young rats from twenty-one litters, each litter of average number six rats, were used, and it was noted whether each animal could see or was blind. This change happens normally at about the thirteenth day after birth. The animals were minced, and extracted three times with excess of boiling alcohol–ether (3 : 1). In the whole extract, total lipoids were determined gravimetrically after extraction with petroleum ether. Cholesterol, of the same extract, was determined colorimetrically by the Liebermann–Burchard reaction.

From the graphs it is evident that the amount of total lipoids increases more quickly with increasing weight in the blind rats than in the rats which could see. A less distinct increase occurs for cholesterol.

This smaller increase of lipoids is not shown in the amount of dry matter of rats, which Schreiber describes in his work. On the other hand, dry matter increases more in rats which can see than in blind rats. Therefore it is evident that at this time the increase of proteins must be higher than the increase of lipoids.

Treatment of animals with anterior lobe of hypophysis results in increased utilization of lipoids, especially of glycerides[3]; cholesterol is not affected in this way. It is possible that the smaller increase of lipoids and greater increase of proteins in rats when they begin to see may be related to a certain state of development of the hypophysis.

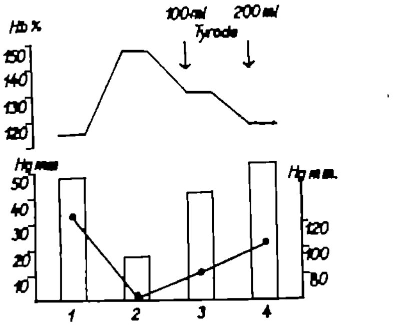
## Response of the Vascular System to Sympathetic Stimuli during Shock

SHORR and co-workers[1], in studying the state of the vascular system in shock, showed that in the later stages of variously induced shock a vasodepressor substance appears in the blood of dogs, and that this substance, injected into rats, reduces the spontaneous vasomotion of the vessels of the mesoappendix and sensitivity to adrenalin. They later identified the substance as ferritine[2]. In their opinion, the vaso-depressor substance has an important role in the patho-mechanism of shock.

In our experiments, we have studied the effect on the blood pressure of splanchnic stimuli and of adrenalin injections in animals in hæmorrhagic or tourniquet shock. Experiments were carried out on seventy-nine dogs under chloralose anæsthetic. Hæmorrhagic shock was induced by gradually drawing 35 ml./kgm. blood; ischæmic shock by 4–5 hr. ligature of the rear limbs (tourniquet). In both types of shock, 90 per cent of the animals succumbed within 7–8 hr. The adrenalin was given intravenously in 20–40 μgm. doses, choosing the dose so far as possible to bring about a rise in blood pressure equal to a 10-sec. splanchnic stimulus. Comparison of the adrenalin and splanchnic sensitivity was made in the same animal before and after inducing shock.

Our results show that, both in hæmorrhagic and in ischæmic shock, the blood pressure following splanchnic stimulus or as the effect of adrenalin pressor has a value of 17–21 mm. mercury, as against the initial 45–50 mm. mercury. Decreased splanchnic and adrenalin responsiveness could already be observed 1–2 hr. before death, when the systemic blood pressure was about 60 mm.

The phenomenon can be explained by Shorr's theory of a vaso-depressor substance; but it seemed possible that the hæmo-concentration, or the reduced quantity of circulating blood in shock, might bring about the diminished adrenalin and splanchnic response. To determine this, in further experiments we investigated the effect of re-injecting the blood drawn, or Tyrode infusions of varying quantity, on splanchnic and adrenalin sensitivity. The rise in blood pressure due to the adrenalin, the systemic blood pressure and percentage hæmoglobin are shown in the accompanying diagram (mean values for eight ischæmic shock experiments). From the diagram can be seen, on one hand, the degree of reduction in adrenalin sensitivity in shock, and, on the other, that when the hæmoglobin-level reaches its initial value as the result of the infusions, adrenalin sensitivity is also re-established. There is a correlation



Effect of adrenalin on blood pressure in millimetres of mercury, □; systemic blood pressure, ●—●; upper curve, hæmoglobin per cent; (1) before inducing shock; (2) during shock; (3) after infusing 100 ml. Tyrode; (4) after infusing 200 ml. Tyrode

between the two values ($r = -0{\cdot}86 \pm 0{\cdot}14$). The splanchnic stimulation behaves in essentially the same manner. In hæmorrhagic shock, transfusion of the drawn blood likewise normalizes the splanchnic and adrenalin responsiveness.

From these results it would seem that, conflicting with the theory of a vaso-depressor substance, the diminution in splanchnic and adrenalin sensitivity in shock is due primarily to the reduced amount of blood in circulation.

More detailed results will appear in the *Acta Physiologica Hungarica*.

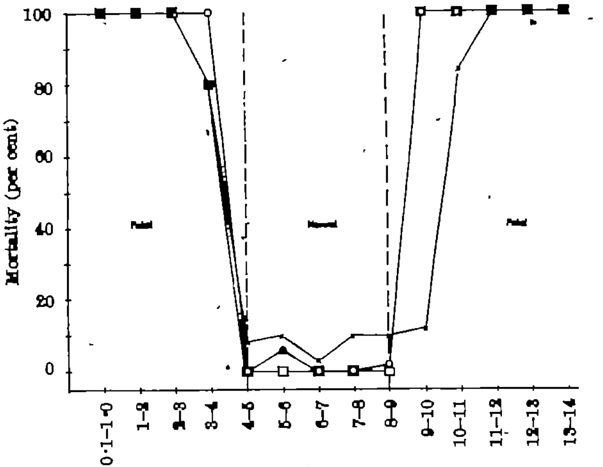
## Effect of Changing *p*H on Developing Trout Eggs and Larvæ

A change in the *p*H value of the surrounding water has been observed to have a marked influence on the life and growth of trout eggs and larvæ. Normally, they are reared in water of *p*H 7·30 ± 0·05 at 10·5° C. The *p*H value of the yolk in living eggs and larvæ is 6·50–6·55, and after death it has the same *p*H value as that of the surrounding water. As a starting point for an investigation of the effect of different *p*H values on eggs and larvæ, they were reared in tap water adjusted to different *p*H's with hydrochloric acid and sodium hydroxide. Such a system would not remain at constant *p*H. Since it was found that a particular quantity of water in a glass vessel containing fifty eggs did not change its *p*H in 6 hr. by more than 1·0 towards the acid side, the water of the experimental container was replaced after 6 hr. with fresh water adjusted to the original *p*H. Buffer solutions were not used to avoid the action of other ions. All the containers were kept in the same hatchery tray at a constant temperature of 10·5° ± 0·5° C., and each container received 50 eggs. The larvæ need more oxygen and give out more carbon dioxide than the same number of eggs, so the quantity of water in each container was increased to five times the original to ensure the proper aeration of the larvæ. A simple average of the mortality percentage of four experiments is shown in the graph. All *p*H values were measured with a glass electrode and Cambridge *p*H-meter at 10·5° C.



— —, Ova one day after fertilization; ○—○—, eyed ova about three weeks after fertilization; □—□—, larvæ one day after hatching

The graph shows that the eggs can develop normally in a fairly wide range of *p*H, outside which there is an abrupt rise in mortality. It also shows that the eyed ova and the larvæ are equally susceptible to *p*H changes, but green ova are more resistant.

*In alkaline medium.* There was endosmosis. The eggs swelled and the vitelline cavity was reduced very much. The yolk became white due to contamination with external water. The frozen sections of the eyed ova showed very little breaking of the yolk emulsion at its surface, and it appeared that metabolic activity was very much slowed down.

*In acidic medium.* In this case there was exosmosis. The egg yolk inside the eggs shrank, and the vitelline cavity widened. The yolk even in the dead eggs was not white, showing that it was not contaminated with external water. The frozen sections of the eyed ova showed an increase in the breaking of yolk emulsion at its surface. The metabolic activity appeared to be accelerated in this case.

It is suggested that the alkali saponifies the lipoids of the vitelline membrane, making it permeable to water, and also retards the activity of the extra-embryonic blastoderm in yolk metabolism. On the other hand, acid does not remove the lipoids of the vitelline membrane and its impermeability to external water is maintained. The acid appears to accelerate the metabolic activity of the extra-embryonic blastoderm on the yolk surface.

In these experiments there can be two factors which would affect the eggs and larvæ: (1) the change of *p*H value of the surrounding medium, and (2) carbon dioxide given out by the eggs and larvæ during respiration. The latter point was raised by Young[1] while studying the effect of changing *p*H values on adult fishes. In the present experiment this factor was negligible because the quantity of carbon dioxide given out by the eggs would be much smaller than that given out by adult fishes. In any event, it was found that the carbon dioxide factor was common to both treated and control containers.

## Occurrence of Nicotine together with Hyoscine in *Duboisia myoporoides* R. Br.

The genus *Duboisia* comprises three species: *D. hopwoodii* F. Muell. is confined to the interior of the Australian continent, *D. leichhardtii* F. Muell. has a restricted occurrence in the highlands of south-eastern Queensland, and *D. myoporoides* R. Br. occurs along the eastern coast of Australia and in New Caledonia. The leaves of all three species contain major quantities of alkaloids; but the genus is unique in that one species, *D. hopwoodii*, contains the pyridine alkaloids nicotine and *nor*-nicotine, whereas the other two contain various alkaloids of the tropane group. Efforts to detect tropane alkaloids among the minor alkaloids of *D. hopwoodii* have failed. Similarly, although the other two Australian species contain volatile bases, the occurrence of nicotine or *nor*-nicotine has not been demonstrated.

A sample of seed of *D. myoporoides* from New Caledonia was recently obtained for us by the South Pacific Commission. Seedlings were established at Canberra both in the field and in a heated glasshouse. Although the plants in the field were stunted, those in the glasshouse grew well and were very similar to adjacent plants of *D. myoporoides* grown from Australian seed.

Alkaloid assays were carried out by a modification of the partition chromatographic method described by Loftus Hills and Rodwell[1]. Working with *D. hopwoodii*, it had been found that nicotine and *nor*-nicotine are well separated by the procedure in routine use for separation of tropane bases. In all chromatograms of material of New Caledonian origin, peaks were obtained in the positions for nicotine, hyoscine and *nor*-nicotine. The identity of hyoscine in each chromatogram was established by preparation of the picrate or reineckate, the melting points of which were not depressed on admixture with the compound prepared from authentic hyoscine. It gave a positive Vitali–Morin reaction, and when run on a paper chromatogram, using butanol – acetic acid – water to form the phase pair, a single spot was obtained with the same $R_F$ value as that obtained with hyoscine. To identify nicotine, the dipicrate was prepared and checked by mixed melting point with nicotine dipicrate prepared from tobacco. The *nor*-nicotine was similarly identified, using *nor*-nicotine from *D. hopwoodii* for comparison. Also, for both these fractions, paper chromatograms showed single spots in the expected positions.

The partition chromatograms also showed small amounts of other bases. Material eluted in the position where hyoscyamine would be expected gave a positive Vitali reaction, and a paper chromatogram showed a spot with the same $R_F$ value as hyoscyamine. The leaf samples contained approximately 0·1 per cent of this material.

The method of assay, although giving reliable quantitative data for hyoscine, only gives an indication of the amounts of nicotine and *nor*-nicotine present, as losses on drying are uncertain[2]. Of the seven samples of *D. myoporoides* from New Caledonian seed examined, the first was a composite bulk from eight field trees, and the remainder were from individual plants in the glasshouse. The amounts of hyoscine, nicotine and *nor*-nicotine, expressed as a percentage of the dry weight of the leaf, are shown in the accompanying table.

This appears to be the first occasion upon which alkaloids of the tropane and pyridine groups have been observed to occur in the same plant, or even in the same species. In the genus *Duboisia* in Australia, these two phytosynthetic mechanisms are sharply isolated by the species boundaries; but they exist together in this New Caledonian form, the origin of which is a matter of conjecture.

*D. myoporoides* (ex New Caledonian Seed)

| Origin of sample | As percentage of dry weight of leaf | | |
|---|---|---|---|
| | Nicotine | *nor*-Nicotine | Hyoscine |
| Field, Canberra A.C.T. | 0·9 | 0·2 | 0·4 |
| Single plants, glasshouse, Canberra, A.C.T. | 0·7 | 0·2 | 0·25 |
| | 0·6 | 0·3 | 0·4 |
| | 0·9 | 0·2 | 0·4 |
| | 0·5 | 0·25 | 0·35 |
| | 0·7 | 0·3 | 0·5 |
| | 0·7 | 0·2 | 0·55 |

The geographical remoteness of New Caledonia from the area in which *D. hopwoodii* occurs and the morphological similarity of this material with *D. myoporoides* do not support a theory of hybrid origin. Possibly internal changes involving the pattern or nature of the genes were responsible. On the other hand, the New Caledonian material may be a relict of a primitive form from which the genotypes of the Australian mainland originated.

## Uptake of Dyes into Cut Leaves

The limitation of petiolar uptake of solutes by detached leaves shown in the following experiments does not seem to have been previously recorded.

Leaves of *Atropa belladonna* L. and of cherry laurel (*Prunus laurocerasus* L.) were placed with their petioles in dilute solutions of the basic dyes methylene blue and safranin, and of the acid dye acid fuchsin. In two to three hours approximately 0·25 ml. of the acid fuchsin had been taken up and could be seen by the naked eye, and by the microscope, to have reached the finest ramifications of the leaf vascular system.

Uptake of the basic dyes was very much slower; but the safranin experiment was prolonged until approximately 0·5 ml. had been taken in. No colouring of the leaf was noticeable, and lengthwise cutting showed that all the dye had been retained by the first half-inch of the petiole; methylene blue, which is not so basic, had stained approximately the first inch. Such an immovable accumulation of dye molecules in the xylem vessel lumen would naturally impede fluid intake, and the leaves did, in fact, wilt.

The experiment was repeated for cherry laurel leaves using penicillin and streptomycin, which are respectively acidic and basic antibiotics. The concentration in both cases was 1,000 units/ml., and the solutions were at pH 5. Uptake of penicillin solution was rapid, but of streptomycin solution very slow. At varying times disks were removed by means of a cork-borer from parts of the leaf distal and proximal to the petiole. These were finely chopped, and tested for antibiotic content in the usual manner with bacteria-seeded test plates. A well-marked concentration of penicillin was found to have entered the leaves in only 45 min., whereas streptomycin could not be detected after four hours.

Such facts are satisfactorily explained by supposing the xylem elements to be negatively charged. As such they would hinder, or prevent, the intake of basic organic molecules, which are positively charged, while not interfering with, or even accelerating, the intake of negatively charged acidic molecules. There seems to be no reason why this condition should not prevail in the intact xylem system; but it would scarcely affect such mobile positively charged particles as the sodium or potassium ions commonly found there.

The origin of the charge is possibly as follows[1]: negatively charged OH′ ions, formed from ionized water molecules, induce a dipole separation of charges in the non-ionizing cellulose and lignin of the xylem. This polarization causes an attraction to arise between the OH′ ions and the xylem surface, which is sufficiently great to overcome the thermal energy of the ions. Consequently, the OH′ ions are bound to the xylem surface, which thus becomes negatively charged. For explanation of the special ability of anions, particularly OH′ ions, to induce charged surfaces of this type, ref. 1 should be consulted.

Petiolar feeding of leaves may be said to have as its objective the administration of substances to the mesophyll cells in the most 'natural' way. The above results suggest that the method may be unsuitable for administering basic substances, in which case infiltration technique should be used.

It might further be added that while acidic substances, as judged from rapid petiolar intake of their solutions, enter the xylem with ease, this is no guarantee that they obtain rapid access to the chlorophyll-containing cells. Speed of access to these cells will be determined by the semi-permeable properties of the close-fitting cells sheathing the xylem and its branches; for an unstable substance like penicillin any considerable delay would be serious.

## Orientation of Telotrematous Brachiopoda

A study of the development of the rhynchonellid, *Tegulorhynchia nigricans*, Sowerby, shows the larva to be furnished with two pairs of large tufts of long setæ set on the hind margin of the mantle rudiment. The members of one pair lie dorso-laterally, those of the other pair laterally. On the mid-ventral surface of the larval mantle is a longitudinal thickening of ciliated cells some 70 μ long and reaching to the hind edge. Two bands of muscle fibres pass forward inside the larval pedicle and are finally inserted one each side of the mid-dorsal line of the base of the mantle.

After attachment and mantle reversal, the dorso-lateral tufts of setæ are found on the edge of the brachial valve near the mid-line, and the lateral tufts are found laterally on the edge of the pedicle valve. Lying mid-longitudinally on the inner face of the pedicle valve is a short cellular thickening which is probably derived from that on the mid-ventral side of the larval mantle. Adjustor muscles pass between the stalk and the pedicle valve. Other muscle pairs are present, notably the divaricators. It is clear that the ventral part of the larval mantle gives rise to the pedicle valve of the young adult and that the dorsal portion of the larval mantle provides the brachial valve.

The fact that immediately after mantle reversal a pair of adjustor muscles passes between the stalk and the pedicle valve shows that the larval muscle bands consist of more than adjustor elements and that their inner portions give rise to other muscles, those likely being the divaricators, the upper ends of which lie alongside the ends of the adjustors inserted on the pedicle valve.

The well-marked features of the late larva of *Tegulorhynchia* make possible the ready relation of the external structures of that phase with those of the young adult immediately after metamorphosis.

In the case of *Terebratella inconspicua* Sowerby, the development of which has been described[1], the larva possesses little externally which can be reliably followed through metamorphosis. The setæ are minute, few, squarely set about the long axis, and useless for orientation. The median ventral thickening, about 35 μ long, has not been traced immediately after reversal; but a small thickening appears on the inner face of the pedicle valve when the mouth forms, and projects somewhat into the latter. Whether this is a reappearance of the original thickening is not certain. The guide through metamorphosis for orientation was taken as the pair of muscle bands in the larval pedicle, passing forward to the dorsal side. These muscles were considered to become the pair of adjustors of the young adult, thus making the pedicle valve morphologically dorsal.

The observations on the metamorphosis of *Tegulorhynchia* bring into question the value of the interpretation of the metamorphosis of *Terebratella inconspicua*. The interpretation of the latter metamorphosis in terms of that of *Tegulorhynchia* simplifies what would otherwise be complex and is in accord with similarities of other kinds which exist in the two developments.

The earlier interpretation of the metamorphosis of *Terebratella* is discarded and is replaced by one which makes it agree essentially with that of *Tegulorhynchia*. The orientation of the two young adult brachiopods is then similar to that of *Lingula*, as described by Yatsu[2].

## Determination of Adrenalin and Noradrenalin in the Human Fœtal Adrenals and Aortic Bodies

The adrenalin content of the fœtal adrenals has been studied in experimental animals by biological and chemical methods to a relatively insignificant extent; corresponding studies on human material are scarce. Lelkes[1] has shown by biological methods that as early as towards the end of the third fœtal month the human adrenal gland already contains adrenalin, and beginning with the fifth month it can also be demonstrated more abundantly in Zuckerkandl's body. The noradrenalin content of the human fœtus has scarcely been studied at all. Therefore, we have attempted to make a chemical determination of the noradrenalin and adrenalin in human fœtal adrenals and Zuckerkandl's body at different stages of the intrauterine period.

The series comprised nineteen cases ranging from 230 up to 4,270 gm., in which determinations were performed by the micromethod. In collecting the material, particular consideration was given to its freshness. Noradrenalin and adrenalin were determined in a trichloracetic extract according to v. Euler's and Hamberg's iodine oxidation reaction[2], carrying out oxidation both at $pH$ 4 and 6.

During the last three months of the intrauterine period the total catechols of the adrenals averaged 71 μgm. The corresponding figures for the aortic bodies were 40 μgm. and 11 μgm. respectively. The ratio between the catechols of the aortic bodies and the adrenals remained constant throughout fœtal life. The total catechols of the adrenals and aortic bodies per kgm. of body-weight were somewhat less than the corresponding amount in normal adult adrenals (in cases of sudden death).

A considerable part of the total catechols in the adrenals consisted of noradrenalin; in three-quarters of the cases noradrenalin accounted for more than half, which is notably more than in adult humans. The preponderance of noradrenalin in the aortic bodies was even more pronounced, amounting on an average to five-sixths of the total catechols during the last three months of intrauterine life.

The concentration of catechols in the fœtal adrenals was found to be considerably less than in the adult glands (1 : 50), due to the large cortex characteristic of fœtal life.

No clear correlation could be established between concentrations of catechol in the organs studied and difficulties of labour. Normal amounts of catechol were found even in prolonged asphyxia.

A full account of this work is being published elsewhere[3].

## Spontaneous Parthenogenesis in a Fish

THE guppy, *Lebistes reticulatus*, is a viviparous fish the reproductive physiology of which has been well studied (bibliography in Gordon[1]). A female, *D*9, of English domestic stock of this species born October 5, 1950, was separated from adult males twelve days after birth. The litter of which she was a member were placed in separate jars when thirty-nine days old. The first sign of differentiation of the anal fin into a gonopodium was seen in one of her brothers twelve days later, the family being raised at 20° C. The isolated female, at the age of 216 days, bore a female offspring which died at the age of 304 days. The mother was then mated to a male litter-mate, and bore four litters of at least twenty-six, of which twenty-four were females and one male. The male mated with *D*9 died before the birth of the second litter, consisting of seven females and one male which were separated from each other at the age of four days. One of these females, *DD*20, gave birth to three young at the age of 193 days.

The first example of unexpected births could be explained by fertilization of the female by an adult male during her first twelve days or by an immature brother during the first thirty-nine. The second could only be explained by fertilization of a female aged less than five days by a male of the same age, which, however, showed no sign of gonopodial differentiation until thirty-eight days old. Even if the gonads matured early, it is difficult to see how internal fertilization could have been achieved with an unmodified anal fin. Winge[2], after prolonged experience, states that "males and females should be separated as soon as the sex can be determined, i.e., 2–3 weeks before maturity is reached".

Amateur breeders have described parthenogenesis in fish verbally on several occasions; but do not seem to have published any repetition of their observation under controlled conditions. Considering the ease with which artificial parthenogenesis can be obtained in some vertebrate groups[3], the same phenomenon would be expected to occur spontaneously, and has been reported[4].

(*February* 14, 1953. Three further anomalous litters have been born. All nine fatherless fish old enough for the sex to be recognized are females.)

## Somatic Reduction Division in the Development of the Sea Urchin

IN the sixteen-cell stage of the sea urchin egg, four micromeres occur around the vegetal pole. At the following division, which is delayed in the micromeres[1], these cleave off 'small micromeres', which behave in many respects differently from the rest of the embryo[2]. They do not flatten against their neighbours, appear optically empty in dark-field illumination, and cannot be vitally stained, for example, by nile blue sulphate. In all these respects the small micromeres resemble the polar bodies[2]. This suggests a deeper similarity, namely, that the small micromeres function as 'somatic polar bodies', the division leading to their formation implying a reduction of the chromosome number.

Studies were made of sections of *Paracentrotus lividus* (Lamarck) from Naples. The diploid chromosome number of this species[3] is 36. In three embryos with the micromere division in late telophase to early anaphase, the number was found to be 18. In some embryos with early anaphase stages and the chromosomes in two different sections, the chromosome number of the two groups varied between 17 and 21, the higher numbers probably depending on fragmentation of some chromosomes. In many divisions in metaphase the number of chromosomes could not be exactly counted, but was estimated to fall between 32 and 40. It is thus obvious that the division of the micromeres implies a reduction of the chromosome number to half.

Material of *Strongylocentrotus drœbachiensis* (O. F. Müller) was obtained on the west coast of Sweden. Also in this species the division of the micromeres yields haploid nuclei. The haploid number calculated from seventeen haploid and sixteen diploid chromosome counts was 20·2. This agrees well with that observed from an equatorial plate in polar view of a micromere. Here a pairing of the forty chromosomes is taking place, being equivalent to the 'secondary pairing' in mitosis (Diptera and polyploid plants) and meiosis (plants) (cf. Darlington[4]).

Somatic reduction divisions seem not to have been observed in animals, but are known to occur spontaneously in plants, and have also been experimentally induced (cf. Battaglia[5]).

The micromeres and their descendants have very important functions. During the blastula stage this material has a high potency in restraining the tendencies towards extension of the animal differentiations and, when transplanted into isolated animal halves, in inducing vegetal differentiations[6]. Later, it produces skeletal substance. Possibly these functions depend upon the haploid state. An experimental analysis of these and related problems is in progress.

A detailed account of this work will appear in *Experimental Cell Research.*

## Reversal of Phototaxis in Prepupæ of Hymenoptera (Tenthredinidæ) caused by Amyl Acetate Vapour emanating from Marking Paint

In autumn the grass-feeding larvæ of *Tenthredopsis litterata* Geoff. and *T. nassata* F. undergo an ecdysis prior to entering the soil at plant roots, where they remain as overwintering non-feeding prepupæ until pupation occurs in the following summer.

The newly formed prepupæ, although lethargic, exhibit positive phototaxis; but within a period of two or three days they become more active and photonegative. This negative phototaxis appears to direct them to the pupation site in soil, and at present there is no evidence that a gravity reaction is involved.

While investigating the details of the taxis mechanism, a cellulose lacquer was used for occluding in part the vision of active photonegative prepupæ. For a period lasting from a few minutes up to two hours, prepupæ so treated became strongly photopositive, but afterwards reverted once again to their pre-treatment photonegative condition. Further experiment showed that paint placed on other parts of the body produced the same effect, and that this reversal of reaction to light could also be caused by previous treatment for a short period with the vapour of amyl acetate, or handling by instruments contaminated by this vapour. Prepupæ so treated, after being photopositive for a while, returned to their original photonegative condition fairly abruptly and usually within a minute of such a reversal tendency being observed. Ethyl acetate, acetone and chloroform vapours did not alter the reactions of prepupæ to light.

The above observations were made in a dark room on prepupæ moving in a horizontal plane with respect to a diffuse lateral beam of light. The beam emanated from a 100-watt lamp bulb placed 45 cm. from the experimental area and shone through an aperture 5 cm. × 3 cm., across which was placed a glass vessel containing water. Further experiments were conducted to ensure that variation in light intensity, heat gradients, nature of substratum and previous exposure of prepupæ to light were not responsible for the observed reversal of behaviour.

Since amyl acetate is a constituent of paints which may be used in various experiments involving insect behaviour, it is felt that these observations might be of particular interest to workers in such fields.

## Manganese Requirements of Tomato Plants at Different Phases of Growth

During investigations on the iron and manganese requirements of plants[1], it was decided to determine whether tomato plants required a continuous supply of manganese throughout their growth or whether the element was more essential at one phase than at another. Investigations on similar lines have been reported by Gericke[2] for wheat and by Brenchley[3] for barley. These workers, however, were concerned with the major nutrient elements.

The method used was the water culture technique[1] and the general plan of the experiment is shown in Table 1.

Table 1

| Treatment designation | Period I 1st 2 weeks | Period II 2nd 2 weeks | Period III 3rd 2 weeks | Period IV 4th 2 weeks |
|---|---|---|---|---|
| *A* | + Mn | − Mn | − Mn | − Mn |
| *B* | + Mn | + Mn | − Mn | − Mn |
| *C* | + Mn | + Mn | + Mn | − Mn |
| *D* | + Mn | + Mn | + Mn | + Mn |
| *E* | − Mn | + Mn | + Mn | + Mn |
| *F* | − Mn | − Mn | + Mn | + Mn |
| *G* | − Mn | − Mn | − Mn | + Mn |
| *H* | − Mn | − Mn | − Mn | − Mn |

Manganese as manganese chloride and iron as ferric citrate were supplied at concentrations of 0·5 p.p.m. manganese and 1·0 p.p.m. iron in the culture solution. After a two-week germination period in the absence of iron and manganese, the seedlings were transferred to the various treatments (four replicates of each). The culture solution was changed weekly.

The plants in treatment *A* showed symptoms of manganese deficiency in the upper leaves five weeks after the beginning of the treatment. The plants in treatments *B*, *C* and *D* were quite normal and were setting fruit on the first truss at the end of the experimental period. In the second series (treatments *E*, *F*, *G* and *H*), the following observations were made: (1) treatment *E* produced normal plants; (2) manganese-deficiency symptoms appeared in treatment *F* five weeks after sowing but plants recovered two days after manganese was supplied; (3) in treatment *G* the plants developed manganese-deficiency symptoms and only partially recovered from these when manganese was supplied; and (4) treatment *H* produced severe manganese-deficiency symptoms and no flowers were produced.

The average yield (Table 2) of plants from treatment *A* was significantly less than the yields produced by treatments *B*, *C*, *D* and *E*, all of which were equivalent to each other. The plants from treatments *F*, *G* and *H* reflect the delayed manganese supply in their low dry-weight yields. These observational and yield data indicate that, for normal development, from germination to the formation of young fruits on the first truss, manganese must be available at least for four weeks after the initial two-weeks growth in its absence.

Table 2

| Treatment designation | Average dry weight (gm.) Roots | Tops | Whole plant | Conc. of manganese in tops (p.p.m.) |
|---|---|---|---|---|
| *A* | 1·09 | 10·19 | 11·28 | 10 |
| *B* | 1·43 | 12·45 | 13·88 | 62 |
| *C* | 1·68 | 12·50 | 14·18 | 120 |
| *D* | 1·66 | 13·74 | 15·40 | 123 |
| *E* | 1·54 | 12·80 | 14·34 | 109 |
| *F* | 0·99 | 6·78 | 7·77 | 120 |
| *G* | 0·41 | 4·08 | 4·49 | 94 |
| *H* | 0·33 | 3·44 | 3·77 | 5 |

From the manganese concentrations in the tissues (Table 2), it is clear that treatment *A* did not supply sufficient manganese, but that periods of treatment for the first four or more weeks provided adequate quantities for normal growth. This was also true when manganese was withheld for two weeks only (treatment *E* with 109 p.p.m. manganese). When manganese was available during the last four and two weeks of the experimental period, it accumulated to 120 and 94 p.p.m. respectively; but adequate utilization of this amount was not reflected in the dry-weight yields at the time of harvest. A response to this manganese might have been obtained if the experiment had been continued longer.

A further experiment was designed to investigate the manganese requirements during the first six weeks of growth. The treatments are summarized in Table 3.

Table 3

| | Treatments: *J* 8 weeks with Mn | *K* 3rd and 4th weeks only with Mn | *L* 3rd week only with Mn | *M* 4th week only with Mn |
|---|---|---|---|---|
| Average dry weight of plants (gm.) | 18·97 | 20·68 | 19·97 | 19·49 |
| Conc. of manganese in tops (p.p.m. dry wt.) | 108 | 46 | 27 | 25 |

All plants irrespective of treatment were normal at all stages, the dry-weight yields showed no significant difference between each other and the average manganese content of the tops was adequate (Table 3).

Thus, if manganese was available for only one week during the fifth or sixth week after sowing, no adverse effects resulted. It was observed that treatment *M* in the second experiment did not show any signs of manganese deficiency during the fifth week as did treatment *F* in the first experiment. This difference could only be attributed to external factors beyond control. It was unfortunate that a more comprehensive experiment was not possible at this stage. However, the results indicated that, for the period from germination to the setting of fruit on the first truss, manganese was necessary only during the fifth or sixth week after sowing. The manganese absorbed during this short period was sufficient for normal growth for a further five or four weeks. Addition of manganese to cultures deprived of this element for periods longer than six weeks had little beneficial effect by the end of the tenth week after sowing.

The work reported here was carried out in the University of Birmingham.

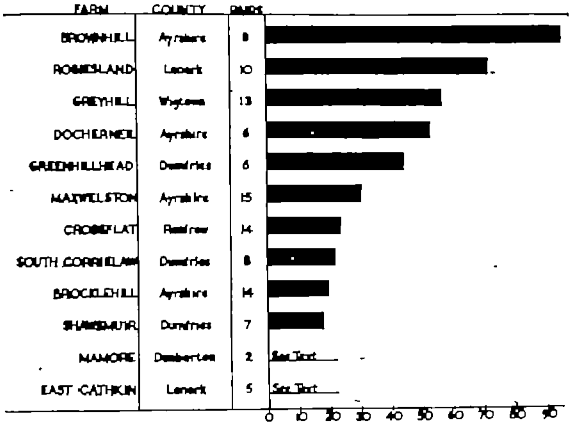
## Feeding of Seaweed Meal to Lactating Cows

The butterfat production of lactating dairy cows in the west of Scotland has been shown to be increased by the single addition of copper sulphate to the diet one to six days after feeding the supplement[1]. The response to the feeding of foodstuffs rich in trace elements (including copper) should show a similar effect on the fat production of the cows in this area. Such a foodstuff is available as seaweed meal.

A supply of the meal (dried, milled *Ascophyllum nodosum*) was obtained from the Institute of Seaweed Research, Inveresk Gate, Musselburgh, and a sufficient quantity was distributed to seventeen West of Scotland dairy herds whose owners co-operated in the experimental work. The method adopted in drawing up the groups of animals for the experiment on those farms has already been described[1]. The meal was delivered to each farm in hundredweight canisters; and, in the experimental group, one scoopful (200 gm.) of the afternoon production ration in the feeding trough of each cow was measured back, and in its place a similar quantity of seaweed meal was substituted. The thorough mixing of the seaweed meal with the production ration was effected in the trough.

A number of cows in the experimental group (those which had calved six months or more beforehand) experienced difficulty in consuming the whole of the production ration containing the seaweed meal, and in five herds the experiment had to be terminated after a day or two. In the other twelve herds, however, despite occasional refusals, the meal continued to be fed for a period of three weeks to one month. After this time a further daily test of the milk and



fat production of the experimental and control animals was carried out.

The full results of the experiment are shown in the accompanying chart. The responses obtained in two of the herds (markedly positive in both cases) are not shown; in all the other herds the number of comparable pairs is six or more.

In all cases a positive response was obtained in the fat production of the animals after the inclusion of seaweed meal in the ration. The magnitude of the response varied greatly between cows and between herds. It is noteworthy, however, that in the case of some of the herds in which the response was greatest (Brownhill, Greyhill and Docherneil) the disease 'swayback' in lambs was experienced during the 1951 lambing season in the sheep flock. Swayback has been shown to be controlled by the administration of copper sulphate to the ewe immediately before lambing[2].

The results were examined by the staff at Rothamsted Experimental Station, from whom the following was received: "The treatment has a real effect although apparently not large enough to be detected on most single farms. The standard error is calculated from $SW(y - \bar{y}_w)^2$, where $W$ is the number of pairs at a farm and is appropriate if the weights are inversely proportional to the within farm variances".

The storage of copper in the liver three days after drenching has been shown to be less than 10 per cent when comparable doses of copper sulphate (0·4–2 gm.) were administered to mature sheep. Usually the amount stored was less than 3 per cent of the dose administered[3].

In some herds the inclusion of seaweed meal in the ration (200 gm. per day) for a period of three weeks would appear to stimulate the fat production of the dairy cow to a greater extent than the administration of a single dose (10 gm.) of copper sulphate (cf. ref. 1).

Further experiments are being conducted to determine whether copper is the sole nutrient responsible for the increased fat production of the cow when seaweed meal is included in the ration.

## Electron Diffraction Study of the Hydrogen Bonds in Boric Acid

IN recent years the techniques of X-ray diffraction structure analysis have been refined to such an extent that, with careful work, the positions of hydrogen atoms in a structure may be determined when each hydrogen atom is bound to a single atom. The detection of a hydrogen ion in a hydrogen bond, however, is a much more difficult task, since only a fraction of an electron can be considered as localized near the proton. This amount of ionization reduces the atomic scattering factor for X-rays. However, the atomic scattering factor for electrons is correspondingly increased since this is given by $\epsilon = (Z - f)\lambda^2/\sin^2\theta$, where $Z$ is the atomic number, $f$ is the X-ray scattering factor, $\lambda$ is the effective wave-length of the electron beam and $\theta$ is the Bragg angle. Hence, hydrogen ions in hydrogen bonds should be detected more readily in structure analyses based on electron diffraction data. Techniques for structure analysis using single-crystal electron diffraction patterns have been evolved and will be described elsewhere. They have been applied to the study of the structure of boric acid layers.

Zachariasen[1] has shown that boric acid has a layer lattice structure. The layers are composed of planar $BO_3^{3-}$ groups joined by hydrogen bonds, and have hexagonal symmetry. These layers are stacked in such a way that the unit cell is triclinic and contains portions of two layers.

Boric acid crystals, formed by evaporation from aqueous solution, which are small enough to give good single-crystal spot patterns (that is, a few hundred angstroms in thickness and a few microns in diameter) show a high degree of disorder in the stacking of the layers. Observations on a number of substances seem to indicate that such stacking disorder occurs almost without exception in very small crystals with layer-lattice structure. Many of the 'two-dimensional' or 'cross-grating' spot patterns reported in the literature may be explained in this way.

If the stacking of the layers were completely random except that all layers had the same orientation, the diffraction pattern would be the same as that of a single layer. For boric acid, although the electron diffraction spot patterns show very nearly a hexagonal symmetry when the beam is perpendicular to the plane of the layers, the intensities deviate slightly from those to be expected for complete randomness.

A method has been developed whereby the amount and nature of the stacking order can be determined provided that the structure of the layer is known approximately, and this information can be used for deriving the intensities corresponding to a single layer from the observed intensities. The details of this method will be published elsewhere.

The intensities measured from a single-crystal electron diffraction pattern, taken with the beam nearly perpendicular to the layers, were corrected in this way. The Fourier projection of the potential distribution in a boric acid layer, calculated from the corrected intensities, is shown in Fig. 1. The atomic positions are indicated clearly. The groups of three oxygen atoms surrounding a boron atom, and the arrangement of these groups in the unit cell, are exactly as found by X-ray work. However, whereas Zachariasen assumed that the hydrogen ions were located half-way between two oxygen atoms, it is

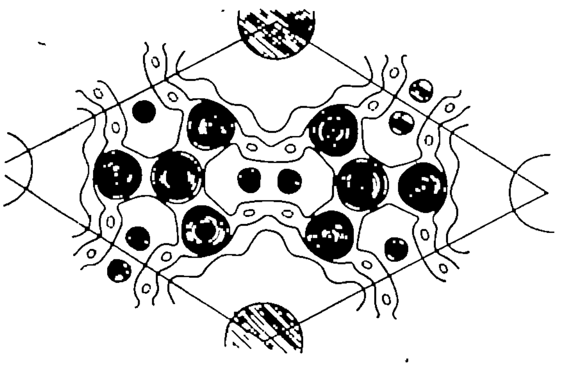

Fig. 1. Fourier projection of a boric acid layer. The full contours mark equal increments in potential in arbitrary units. The dotted contour represents a half increment

seen that the most favoured position for the hydrogen ions is close to one or the other of the two oxygens. The O—H distance is approximately 1·05 A. The hydrogen bonds occur in pairs between pairs of oxygen atoms in adjacent $BO_3^{3-}$ groups, and it is to be noted that the hydrogen positions do not lie on straight lines between oxygen atoms as might be expected, but are displaced in each case towards the neighbouring hydrogen bond. This appears to result from a tendency for the formation of a hydrogen bond from an oxygen atom not only to its nearest neighbour in the adjacent $BO_3^{3-}$ group, but also diagonally across to its second nearest neighbour. For such a diagonal bond it is to be expected that the most favoured position for the hydrogen ion would be approximately 1 A. from an oxygen atom. The resulting hydrogen distribution may be considered as resulting from the combination of the canonical arrangements shown in Fig. 2.

It seems probable that this type of interaction between parallel hydrogen bonds may occur in many crystals where the geometry of the structure is favourable, and may play an important part in determining the structure of some organic compounds, such as the carboxylic acids, and proteins.

Another point of interest in the Fourier projection (Fig. 1) is that the boron and oxygen peaks are very nearly equal in height in spite of the large relative difference in atomic numbers. This effect may be ascribed to the state of ionization of the atoms. The intensities of electron diffraction spots are much more sensitive to the degree of ionization than are the X-ray diffraction intensities, particularly for spots of low indices. Cations have more, and anions less, scattering power than the corresponding neutral atoms. Hence it seems possible that different ionization states may be distinguished readily by such an electron diffraction structure analysis.

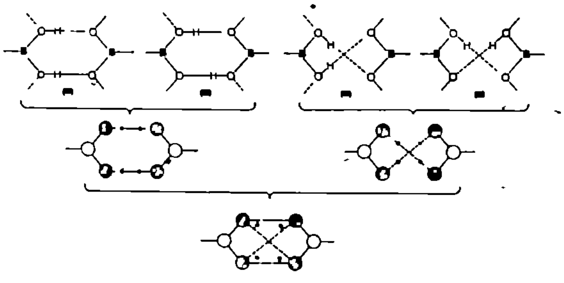

Fig. 2. Combination of arrangements of hydrogen ions in hydrogen bonds between four oxygen atoms to give the observed distribution

I wish to express my gratitude to Dr. A. L. G. Rees for discussion on the interpretation of the hydrogen-bond configuration.

## Intermolecular Force and Transport Coefficients

The Chapman–Enskog theory of non-uniform gases expresses the transport properties in terms of a set of collision integrals[1] which depend on the law of molecular interaction. These integrals have been evaluated for various molecular models and the computed values of the transport coefficients have been compared with the experimentally observed values by Chapman and Cowling. Hirschfelder, Bird and Spotz[2], Winter[3] and others have shown that the Lennard-Jones 12 : 6 potential energy function

$$E(r) = 4\epsilon\,[(r_0/r)^{12} - (r_0/r)^6] \qquad (1)$$

is more in accord with the observed properties of gases than any other model, but the values of the force constants $\epsilon$ and $r_0$ employed by them were deduced from viscosity data. It is well known that the coefficient of thermal diffusion is far more sensitive to the type of molecular interaction than the three elementary gas coefficients. We have, therefore, utilized the data on thermal diffusion, and in particular the variation of the thermal separation ratio $R_T$ of argon isotopes with temperature, to calculate the force constant $\epsilon$.

As shown by Jones and Furry[4] and others, $R_T$ for the case of isotopes is given by:

$$R_T = \frac{16{\cdot}9\,(C-1)\,(1+A)}{A\,(11-4B+8A)}, \qquad (2)$$

where $A$, $B$, $C$ are known functions of the various collision integrals $W^l(n\,;\,kT/\epsilon)$. Equation (2) shows that $R_T$ does not involve $r_0$ and depends only on $\epsilon$ and $T$. It is therefore possible to calculate $\epsilon$ from equation (2) for argon at different temperatures, quite independently of whether $r_0$ is constant or not, by plotting $R_T$ $\epsilon$ versus $T$ and $R_T$ (from equation 2) versus $x$, where $x = kT/\epsilon$. Comparison of the two curves at various corresponding points readily gives $\epsilon$ at different temperatures, the values thus obtained being given in the accompanying table (col. 2). These values of $\epsilon$ are much more accurate than those obtained by others from viscosity and virial coefficient data, since this method, in addition to being far more sensitive, does not assume the constancy of $r_0$.

The figures in the table show clearly a slow decrease in the value of $\epsilon$ with decrease of temperature. It is true that the experimental values of $R_T$ have the

| Temp. (° K.) | $\epsilon/k$ (° K.) | $r_0$ in A., from viscosity | $r_0$ in A., from self-diffusion |
|---|---|---|---|
| 120 | 115·0 | 3·478 | 3·473 |
| 140 | 116·6 | 3·468 | 3·447 |
| 160 | 120·8 | 3·443 | 3·432 |
| 180 | 120·0 | 3·449 | 3·424 |
| 250 | 135·1 | 3·370 | 3·337 |
| 300 | 142·9 | 3·344 | 3·319 |
| 350 | 152·2 | 3·321 | 3·296 |
| 400 | 158·1 | 3·309 | |
| 480 | 165·5 | 3·300 | |
| 550 | 168·3 | 3·293 | |

most probable errors of ± 5 per cent, which is likely to produce an error of ± 15 per cent in the value of $\varepsilon$ at high temperatures and of about ± 5 per cent at very low temperatures. Nevertheless, the decrease in the value of $\varepsilon$ is definite and unmistakable, though the magnitudes may be much in error. These investigations thus show that the 12 : 6 potential function can represent the interaction even over a long range of temperatures, provided $\varepsilon$ and $r_0$ (as will be seen later) are varied very slowly with temperature. Exact calculations by us from viscosity data also show an unmistakable tendency for $\varepsilon$ to increase with increase of temperature. Using these values of $\varepsilon$ in the expressions for viscosity and self-diffusion, $r_0$ at different temperatures has also been found, the values being given in the table.

This variation of $\varepsilon$ and $r_0$ can be accounted for theoretically. Writing equation (1) in the form :

$$E(r) = \lambda r^{-12} - \mu r^{-6}, \qquad (3)$$

it can be shown that

$$\varepsilon = \tfrac{1}{4}\mu^2/\lambda, \quad r_0 = (\lambda/\mu)^{1/6}, \qquad (4)$$

where $\mu$ and $\lambda$ are supposed to remain constant. From London's quantum-mechanical formula for the dispersion energy leading to the van der Waals' attraction[5] :

$$E(r) = -\mu r^{-6} - \mu' r^{-8} - \mu'' r^{-10} - \ldots \qquad (5)$$

it is evident that if, for large distances, we limit the formula to the first term only, $\mu$ must be made to increase when the intermolecular distance $r$ is decreased, in order that the single term may still give the attraction correctly. Since at higher temperatures the most effective contribution of the molecular field to the transport properties will be for smaller intermolecular distances, it follows that $\mu$ must increase with increase of temperature. Similarly, it can be shown that the repulsion term $\lambda$ must decrease with rise of temperature. In consequence, $\varepsilon$ will increase and $r_0$ will decrease with rise of temperature. In fact, from equations (4) the effective $\mu$ and effective $\lambda$ can be calculated at different temperatures and are found to be fully consistent with the virial coefficient data. A similar procedure has been used for other gases also. Detailed investigations are being published in a series of papers.

## Ion-exchanging Surfaces in Radiological Decontamination

THE adsorption of radioelements by the walls of glass vessels is recognized as a source of inaccuracy in radiochemical assessments, and the great affinity shown by many radioactive substances for working surfaces in the laboratory is shown by the vigorous chemical and mechanical treatments which are needed for their removal from these surfaces. Chemically resistant metals such as stainless steel and lead have been shown[1] to adsorb phosphorus-32, barium-140 and iodine-131, and complete removal was possible only by removing a thin layer of the surface. Organic materials such as polythene[2] and vinyl chloride-acetate copolymer have been found to be particularly resistant to contamination by aqueous solutions of radioisotopes, and they are extensively employed as constructional materials or protective coatings. We have found that films of unplasticized polystyrene, prepared by brushing a surface with a 30 per cent solution of 'Distrene' in toluene, possess very low adsorption for fission elements (which were in aqueous solution as nitrates). Results of experiments are given in the accompanying table.

RETENTION OF FISSION PRODUCT ISOTOPES BY POLYSTYRENE AND SULPHONATED POLYSTYRENE

| Surface | Beta/gamma count after 1 min. immersion in fission products solution (10,000 counts min.$^{-1}$, c.c.$^{-1}$) | Beta/gamma count after washing with 5 per cent ammonium citrate for 3 min. |
|---|---|---|
| Polystyrene | 108 counts/min.<br>58<br>65<br>85 | 5 counts/min.<br>3<br>2<br>19 |
| Sulphonated polystyrene (prepared by exposing to SO$_3$ for 2 min.) | 769<br>1,091<br>1,470<br>1,140 | 7<br>114<br>235<br>44 |

It was considered that decontamination might be more readily effected if a surface could be rendered ion-exchanging by some means, since it has been established[3] that isotopes of rare-earth elements can be adsorbed on ion-exchanging phenol formaldehyde resins and can afterwards be completely removed by treating the resin surface with an elutriating solution of citric acid. We have recently carried out a comprehensive series of experiments to determine the degree of attachment and relative ease of removal of fission elements from sulphonated polystyrene, which we prepared in the laboratory, and have come to the conclusion that the use of a cation-exchanging material of this kind does not facilitate complete decontamination to the extent that might have been expected. Full details will be reported in due course, but the table shows typical results.

It will be seen that the adsorption of fission elements is higher for the ion-exchanging surface and that elutriation does not bring the final level of activity down to that of untreated polystyrene.

We are indebted to the Admiralty for permission to publish this note.

## Column Procedures for the Salt Fractionation of Enzyme Preparations

Two procedures for fractionating enzyme preparations on a column, somewhat different from the previously described chromatopile[1], have been found useful in preliminary tests.

In the first procedure, a column of the precipitated enzyme in the presence of an inert carrier and in a medium of high salt concentration is eluted with a dilute salt solution. The resulting fractions of effluent are then analysed for enzyme activity and for protein.

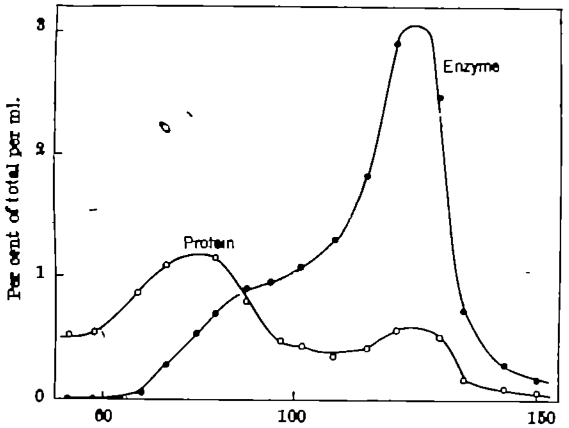

Fig. 1

For example, 50 ml. of saturated ammonium sulphate was added to 25 ml. of a concentrated culture fluid of *B. macerans*[2]. The slurry resulting from the addition of 15 gm. of 'Celite' was poured into a tube and washed with one-third saturated ammonium sulphate, and the effluent was analysed for starch-degrading activity[2] and 'protein' (turbidity of trichloracetic acid suspensions). The results are shown in Fig. 1.

In the second procedure, the impure enzyme preparation in dilute salt solution is allowed to pass down a column consisting of a water-absorbing, insoluble substance. The activity and protein are then eluted with a dilute solution and the effluent fractions are analysed as in the first procedure. For example, 25 ml. of an impure malt alpha-amylase preparation in 0·4 saturated ammonium sulphate was allowed to pass down a column consisting of 60 gm. of calcium sulphate hemihydrate. The amount of the latter was calculated from the experimental dead space of the column on the assumptions that a salt concentration gradient was to be established on the column ranging from 0·4 saturated to 0·7 saturated ammonium sulphate and that hemihydrate would take up the theoretical amount of water. The column was then washed with saturated calcium sulphate solution at 5°. The results are shown in Fig. 2. Equally effective fractionations were obtained using other amylase sources.

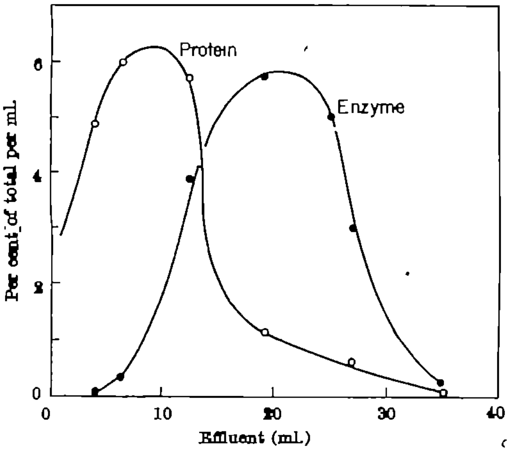

Fig. 2

The effectiveness of both these methods was probably due to the differential extraction-rates of the proteins[3], and possibly to the establishment of salt concentration gradients along the columns. Such a gradient might possibly be established upon properly impregnated paper. In principle, one might use a procedure of the type herein described as a specific activity – solubility test for purity[4].

## An Electrostatic Single Lens permitting Rigorous Calculation

ALTHOUGH for magnetic electron lenses the field[1]

$$B_z(z) = B_0/[1 + (z/a)^2] \qquad (1)$$

is known to permit rigorous calculation, this is not the case for electrostatic single lenses as used in electrostatic microscopes, for which up to now no type permitting exact calculation was known. We shall show in the following that the electrostatic counterpart to (1), namely:

$$\Phi(z) = \Phi_0 - \Phi_0\kappa^2/[1 + (z/a)^2] \; ; \; 0 < \kappa^2 \leq 1 \qquad (2)$$

is also integrable. The differential equation of paraxial rays for this field, which approximates very well to the axial potential distribution of a three-aperture lens, can be transformed into an equation with constant coefficients. A magnetic field of the Glaser-type can be superposed. Inserting in

$$\sqrt{\phi}\, \mathrm{d}(\sqrt{\phi}\, \mathrm{d}r/\mathrm{d}z)/\mathrm{d}z + [\tfrac{1}{4}\, \Phi'' + eB_z^2/8m]\, r = 0 \qquad (3)$$

the new variables $v$, $\varphi$:

$$z = a \,.\, \mathrm{ctg}\, \varphi \; ; \; r = v(\varphi)/\sin \varphi, \qquad (4)$$

which is well known from the bell-shaped field (1), we get:

$$\sqrt{\phi}\, \mathrm{d}(\sqrt{\phi}\, \mathrm{d}v/\mathrm{d}\varphi)/\mathrm{d}\varphi + [\Phi + \tfrac{1}{4}\, (\mathrm{d}^2\phi/\mathrm{d}\varphi^2) + ea^2B_z^2/(8m \sin^4\varphi)\,]\, v = 0. \qquad (5)$$

The fields (1) and (2) become:

$$\Phi = \Phi_0\, (1 - \kappa^2 \sin^2\varphi) \; , \; B_z = B_0 \sin^2\varphi. \qquad (6)$$

Inserting in (5) we obtain

$$\sqrt{1 - \kappa^2 \sin^2\varphi}\, \mathrm{d}(\sqrt{1 - \kappa^2 \sin^2\varphi}\, \mathrm{d}v/\mathrm{d}\varphi)/\mathrm{d}\varphi + [1 + k^2 - \tfrac{1}{4}\kappa^2]\, v = 0 \; ; \; k^2 = \frac{eB_0^2a^2}{8m\Phi_0}. \qquad (7)$$

Changing the independent variable by means of

$$\mathrm{d}\varphi/\mathrm{d}\tau = \sqrt{1 - \kappa^2 \sin^2\varphi}, \qquad (8)$$

we get

$$\mathrm{d}^2v/\mathrm{d}\tau^2 + \omega^2 v = 0, \quad \omega^2 = 1 + k^2 - \tfrac{1}{4}\kappa^2, \qquad (9)$$

and the solutions:

$$v = A \cos \omega\tau + B \sin \omega\tau. \qquad (10)$$

The variable $\tau$ is, from (8), given by the elliptic integral of the first kind:

$$\tau = \int_0^{\varphi} \frac{d\varphi}{\sqrt{1 - \varkappa^2 \sin^2\varphi}}; \quad \text{or } \varphi = \mathrm{am}\,\tau. \qquad (11)$$

The paraxial electron trajectories are

$$r = (A\cos\omega\tau + B\sin\omega\tau)/\sin(\mathrm{am}\,\tau) = C\sin(\omega\tau - \zeta)/\mathrm{sn}\,\tau \qquad (12)$$

with

$$z = a \,.\, \mathrm{ctg}(\mathrm{am}\,\tau) = a \,.\, \mathrm{cn}\,\tau/\mathrm{sn}\,\tau = a \,.\, \mathrm{cs}\,\tau. \qquad (13)$$

Since these functions are tabulated exhaustively, the trajectories are known numerically. The calculation can be carried out on similar lines for the slightly generalized case,

$$\Phi = \Phi_0 + (A + Bz)/[1 + (z/a)^2]\ ; \quad A \gtrless 0. \qquad (14)$$

Mirror effects can be discussed. Third-order aberration coefficients have been calculated. It was even possible to determine the electron paths everywhere, without restriction to the neighbourhood of the optical axis. This can be done by reduction to the problem of two centres. The results will be published in detail in another journal.

I am indebted to Prof. W. Glaser for several discussions on the subject and for the opportunity of carrying out this work in his Institute.

## Long-Delay Ionospheric Echoes at 150 kc./s.

IT is well known that in the ionosphere (a doubly refractive medium) a radio wave splits into two components, commonly designated as the ordinary and extraordinary modes. The propagation characteristics of the medium are determined from the corresponding ordinary and extraordinary indices of refraction. The modes may be appreciably coupled in certain ionospheric regions[1], depending upon the wave-frequency and other factors.

A common experimental technique used for studying these split components, at certain frequencies, involves the use of pulsed radio soundings, in which the components are received as echoes separated in time, since their corresponding heights of reflexion are different. These split echoes are commonly observed near the critical frequencies of the layer.

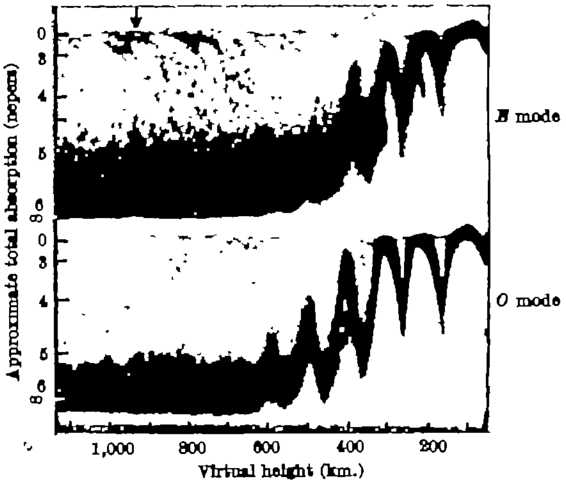
At the much lower frequency of 150 kc./s., the extraordinary mode does not usually, if ever, encounter a 'reflexion condition' below the maximum electron density in the $E$- and $F$-regions; and no great effort has hitherto been directed towards the further tracing of this component into the upper ionosphere. A recent analysis by us[2] employing an estimated equinox, midnight ionospheric model has indicated a strong possibility of substantial reflexion of the 150 kc./s. extraordinary component, from a region well above the maximum in electron density of the $F_2$ layer. This region corresponds to a 'fourth condition for reflexion'[3], and contains extremely rapid variations of refractive index with height. The analysis, involving laborious wave solutions by a special technique[4], indicates virtually total reflexion from a height of 940 km. in the assumed model. Absorption considerations indicate, further, that such an echo may be returned to earth with sufficient amplitude to be recorded by recording techniques which are fairly common. The reason why these echoes have not previously been observed may lie in the fact that no effort has been devoted, at this frequency, to high-altitude searching with high-gain receiving equipment.

The Ionosphere Research Laboratory at the Pennsylvania State College has been procuring regular, extended-range night-time recordings on 150 kc./s., at vertical incidence, for several months, employing a 2-MW. peak power pulse-transmitter and sensitive receiving equipment. The recording height-range during most of the observations extended beyond 1,200 km., with the receiver sensitivity limited by the atmospheric noise-level. To improve the signal-to-noise ratio, photographic time integration is employed, with a 5-min. exposure of 12·5 sweeps per sec.

Occasional 'isolated' echoes have been observed in the range 600–900 km., some of these undoubtedly belonging to the multiple hop system of echoes from the $E$-region, but augmented by ionospheric focusing. The signals were received on a single fixed-loop aerial and no polarization data were available.

Recently, however, a circularly polarized receiving-aerial system has been employed, making possible simultaneous recordings of the unsplit ordinary and extraordinary components. This modification was suggested by polarization considerations of the '940-km. echo' being sought, the latter containing an ordinary to extraordinary amplitude ratio that should be roughly inverse to the same ratio of the multiple-$E$ hop system[5]. The 5-min. recordings were taken every 30 min. during the hours 2000–0400 L.M.S.T.

On the night of November 9, 1952, there appeared, on three different records, an isolated echo corresponding to a height of approximately 900 km. They were visible only on the extraordinary mode. These were followed by similar observations on two additional nights. The record reproduced herewith was taken on November 10, 1952, at 0300 L.M.S.T. The upper and lower photographs display, respectively, the extraordinary and ordinary modes. Height increases horizontally from right to left; the first pulse being the first-hop $E$ reflexion. The vertical scale, indicating signal amplitudes, is quite non-linear due to receiver saturation effects. The amplitude of the echo of great delay (marked by an arrow) is of order of magnitude of that computed in ref. 2.



Among the possibilities for the interpretation of these long-delay echoes are: (*a*) ionospheric focusing of *E* reflexions, (*b*) oblique reflexions from distant ion clouds in the *E*-region, (*c*) large delays due to lateral deviation[6,7], and (*d*) reflexions from the 'fourth reflexion condition', above the maximum of the $F_2$-layer. Ionospheric focusing is immediately ruled out by the fact that the echo polarization is radically different from that of the *E* hops. Other records containing a definite focusing phenomenon do not show the reversed mode that is observed on the long-delay echoes. Oblique reflexions of detectable amplitudes would require an oblique surface of such proportions as to make this explanation extremely unlikely. No calculations have been made on possible time-delays due to lateral deviation; but it does not, at present, seem likely that this could account for the amplitudes and the time-delays of the orders observed.

We believe there is a strong possibility that these long-delay echoes are reflexions from above the maximum of ionization density in the $F_2$-region, and that the reflexion mechanism corresponds to the 'fourth condition for reflexion'. It is hoped that future observations will add further evidence regarding this possibility.

This investigation has been supported by the National Science Foundation under Grant NSF-066 and, in part, by the Geophysics Research Division of the Air Force Cambridge Research Center under Contract AF19(122)-44.

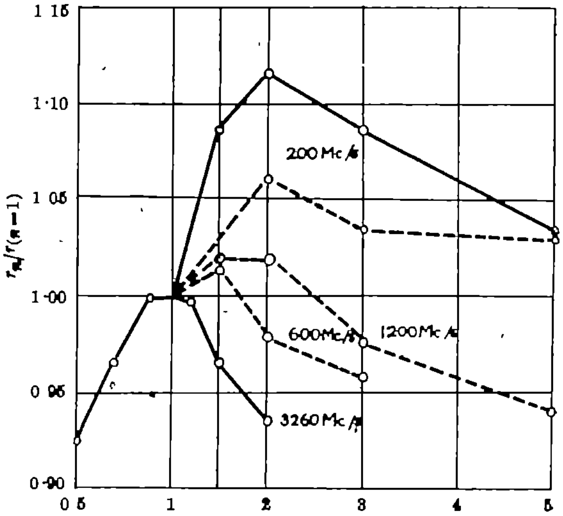
## A Method of Analysis of the Directivity of Solar Radio Emission from Sunspots

IT has been reported previously that the daily values of intensity of solar radio emission are approximately proportional to the whole disk Wolf's sunspot relative number or sunspot area[1,2]. On the other hand, there is a tendency for the intense radiation to be observed when active sunspots are near the central meridian, especially in the metre wavelength region. If the solar radio emission has such a tendency, the daily values of solar radio emission will show better correlation with the sunspot relative number, $nA_1 + A_2$, than the whole disk sunspot relative number, $A_1 + A_2$, where $A_1$, $A_2$ indicate Wolf's relative sunspot number in the central-circle zone (half-diameter circle) and in the outer zone respectively, and $n$ is a parameter which indicates the importance of the sunspots located in the central-circle zone compared with those in the outer zone. To investigate the directivity of solar radio emission from the sunspots quantitatively, the value of $n$ to give a maximum correlation coefficient was determined.



Correlation coefficient $r$ between solar radio emission and sunspot number *versus* $n$, which indicates the importance of the sunspots located in the central circle zone compared with the sunspots in the outer zone. ———, May to August 1951; – – – –, January to June 1951

In the accompanying graph the correlation coefficient $r$, between solar radio emission at 3,260 Mc./s. observed at our observatory and the sunspot relative number, is plotted against $n$, and this is compared with the radio emission at 200 Mc./s. observed at Tokyo Astronomical Observatory in Japan, and 600 Mc./s. and 1,200 Mc./s. observed at Pott's Hill, Sydney; the solid lines are for observations from May to August 1951, dotted lines for those from January to June 1951. The sunspot number is taken from the Tokyo Astronomical Observatory Report.

As shown in the graph, the correlation coefficients between solar radio emission and sunspot relative number have the following maxima:

$n = 1{\cdot}0$ at 3,260 Mc./s. and $r_{\max.} = 0{\cdot}86 \pm 0{\cdot}02$ (May–August 1951)
$n = 2{\cdot}0$ „ 1,200 „ „ „ $= 0{\cdot}68 \pm 0{\cdot}04$ (January–June 1951)
$n = 1{\cdot}5$ „ 600 „ „ „ $= 0{\cdot}54 \pm 0{\cdot}05$ ( „ )
$n = 2{\cdot}0$ „ 200 „ „ „ $= 0{\cdot}54 \pm 0{\cdot}05$ ( „ )
$0{\cdot}49 \pm 0{\cdot}06$ (May–August 1951)

Unfortunately, the standard errors are large at 200, 600 and 1,200 Mc./s. compared with the variations of $r_n/r_{(n-1)}$ shown in the graph, so the results obtained at these frequencies by this method are almost meaningless. The directivities at these frequencies are therefore being investigated using another method of analysis; but it also shows a tendency to result in similar directivities.

It may be concluded that the solar radio emission at 3,260 Mc./s. from sunspots can be observed on the earth at almost equal intensity whatever the location of the sunspots; but at present the directivities are not clear quantitatively at other frequencies.

It is also doubtful if these directivities may be applied to the radio emission at bursts or outbursts.

I should like to express my thanks to Mr. Martin Ryle, of the University of Cambridge, for his helpful criticism.

# FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

## Monday, March 9

University of London (at Bedford College, Regent's Park, London, N.W.1), at 5.15 p.m.—Prof. S. Bergstrom : "Intestinal Absorption of Fats".*

Institution of Electrical Engineers (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Discussion on "Is the Presentation of Technical Literature Adequate ?" (to be opened by Prof. M. G. Say).

Manchester Literary and Philosophical Society (in the Reynolds Hall, College of Technology, Manchester), at 5.30 p.m.—Prof. R. A. Fisher, F.R.S. : "The Evolution of Genetics" (Ramsden Memorial Lecture).*

Royal Geographical Society (at 1 Kensington Gore, London, S.W.7), at 5.30 p.m.—"Western Nepal" (Colour films with commentary by Mr. O Polunin).

University of London (at King's College, Strand, London, W.C.2), at 5.30 p.m.—Prof. R. Plank (Karlsruhe) : "Entropy and Probability".*

Pharmaceutical Society (at 17 Bloomsbury Square, London, W.C.1), at 7.30 p.m.—Dr. J. H. Burn, F.R.S. : "Progress in Biological Standardization".

Royal Institute of Chemistry, London Section (joint meeting with the Woolwich Polytechnic Scientific Society, at the Woolwich Polytechnic, Woolwich, London, S.E.18), at 7.30 p.m.—Dr. A. G. Maddock : "Developments in Experimental Techniques of Radio Chemistry".

## Tuesday, March 10

Zoological Society of London (at the Zoological Gardens, Regent's Park, London, N.W.1), at 5 p.m.—Scientific Papers.

Royal Institution (at 21 Albemarle Street, London, W.1), at 5.15 p.m.—Prof. G. C. Varley : "The Causes of Insect Abundance". (Further Lectures on March 17 and 24).

Institution of Chemical Engineers (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Mr. J. M. Coulson and Mr. R. R. Mehta : "Heat Transfer Coefficients in a Climbing Film Evaporator" ; Mr. F. H. Warner and Mr. K. A. R. Julian : "Natural Circulation in External Evaporators".

Institution of the Rubber Industry (at the Royal Society of Tropical Medicine and Hygiene, 26 Portland Place, London, W.1), at 5.30 p.m.—Mr. L. Landau : "Some Aspects of Latex Dipping" ; at 7 p.m.—Mr. J. M. Buist : "Ageing and Weathering of Rubber, and Methods of Assessment".

British Institution of Radio Engineers, London Section (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 6.30 p.m.—Discussion on "The Standardization of Symbols and the Arrangement of Electronic Circuit Diagrams" (to be opened by Mr. L. H. Bainbridge-Bell).

## Wednesday, March 11

Society of Public Analysts and other Analytical Chemists, Biological Methods Group (joint meeting with the Food Group of the Society of Chemical Industry and the British Region of the Biometric Society, at the Wellcome Research Foundation, 183 Euston Road, London, N.W.1), at 2.30 p.m.—Symposium on "Flavour Assessment".

Institution of Electrical Engineers, Radio Section (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Mr. H. McP. Leyton, Mr. H. A. Nind and Mr. W. S. Percival : "Low-Level Modulation Vision Transmitters, with special reference to the Kirk O'Shotts and Wenvoe Stations".

University of London (at King's College, Strand, London, W.C.2), at 5.30 p.m.—Prof. R. Plank (Karlsruhe) : "Steam Jet Refrigeration".*

## Thursday, March 12

Royal Society (at Burlington House, Piccadilly, London, W.1), at 11 a.m.—Discussion on "The Function and Location of Enzymes in Cells" (to be opened by Prof. J. Z. Young, F.R.S.).

Royal Society of Arts, Commonwealth Section (at John Adam Street, Adelphi, London, W.C.2), at 5.15 p.m.—Prof. Raymond W. Firth : "Social Changes in the Western Pacific".

University of London (at Bedford College, Regent's Park, London, N.W.1), at 5.15 p.m.—Prof. S. Bergstrom : "Formation and Interconversion of Bile Acids".*

Institute of Welding (joint meeting with the Institution of Structural Engineers, at 11 Upper Belgrave Street, London, S.W.1), at 6 p.m.—Mr. H. M. Lewis : "Construction of the New Testing Laboratory of the British Welding Research Association at Abington".

Royal Aeronautical Society (in the Rolls-Royce Welfare Hall, Nightingale Road, Derby), at 6.15 p.m.—Squadron-Leader W. A. Waterton : "Some Aspects of High Performance Jet Aircraft".

## Friday, March 13

Society of Dyers and Colourists, Manchester Section (in the Great Hall, College of Technology, Manchester), at 2 p.m.—Symposium on "Synthetic Fibres".

Royal Astronomical Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Scientific Papers.

Physical Society (at the Science Museum, Exhibition Road, London, S.W.7), at 5 p.m.—Prof. M. Born, F.R.S. : "The Conceptual Situation in Physics and its Prospects of Development" (Guthrie Lecture).*

Bedson Club (in Lecture Theatre I, Chemistry Building, King's College, Newcastle-upon-Tyne), at 5.30 p.m.—Dr. F. Fairbrother : "Catalytic Inorganic Halides and the Friedel-Crafts Reaction" (89th Bedson Lecture).

Institution of Mechanical Engineers (at Storey's Gate, St. James's Park, London, S.W.1), at 5.30 p.m.—"Steels for Steam Power Plant" : a review of work of a Sub-Committee of the British Electrical and Allied Industries Research Association between 1930 and 1951, compiled by A. M. Sage.

University of London (at King's College, Strand, London, W.C.2), at 5.30 p.m.—Prof. R. Plank (Karlsruhe) : "Absorption Refrigeration".*

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Prof. L. Hawkes, F.R.S. : "Geology and Time".

# APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned :

Chemist (Senior Scientific Assistant) at the Central Laboratory, Chiswick, with responsibility for section concerned with wide variety of analytical and investigational work other than metals, fuels, lubricants and paints—The Staff Officer (F/EV.229), London Transport, 55 Broadway, London, S.W.1 (March 13).

Assistant Chemist and Bacteriologist—The Chief Engineer, Mid-Wessex Water Company, Frimley Green, Aldershot (March 14).

Assistant Inspector of Fisheries and Pollution—The Clerk to the Avon and Dorset River Board, Rostherne, 3 St. Stephen's Road, Bournemouth (March 14).

Experimental Officers in the Guided Weapons Department, Royal Aircraft Establishment, Farnborough, for work on design, development and performance of new weapons and associated guidance and control systems ; instrumentation of flight trials and investigation of trials results—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting D.508/52A (March 14).

Assistant Keeper (with honours degree in zoology or equivalent) in Zoology in the Manchester Museum—The Registrar, The University, Manchester 13 (March 20).

Senior Scientific Officer at the High-Speed Aerodynamics Laboratory, Salisbury, Australia, to be responsible, under the direction of a Principal Scientific Officer, for research into problems of stability and control at high speeds—The Senior Representative, Department of Supply, Canberra House, 87 Jermyn Street, London, S.W.1 (March 20).

Instructor/Lecturer of Forestry Field Training School, Forest Department, Ceylon—The High Commissioner for Ceylon in London, 13 Hyde Park Gardens, London, W.1 (March 21).

University Demonstrator in Physics—Dr. F. B. Kipping, Chemical Laboratory, Cambridge (March 21).

Lecturer in Physiology—The Dean of the Medical College, St. Bartholomew's Hospital, West Smithfield, London, E.C.1 (March 25).

Principal (with an industrial background, considerable administrative experience in education, and an intimate knowledge of the whole field of technical education) of the Technical-Vocational High School, Winnipeg—The Secretary-Treasurer, School District of Winnipeg, Winnipeg, Man., Canada ; or The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (April 1).

Tutor (Crop Husbandry) and a Tutor (Animal Husbandry) to train Staffs of Departments of Agriculture and others in the practice and theory of agriculture at sub-university level—The Principal, Eastern Caribbean Farm Institute, Arima P.O., Trinidad, B.W.I. (April 1).

Head of the Department of Biochemistry—The Academic Secretary, Weizmann Institute of Science, Rehovoth, Israel (April 15).

Agriculturist (with a degree in agriculture, preferably with technical, industrial or administrative experience) at the Technical and Scientific Register—The Ministry of Labour and National Service (K Section), Almack House, 26 King Street, London, S.W.1, quoting G.6/53A.

Analytical Chemist (temporary) for work arising from experiments with farm animals—The Secretary, Rowett Research Institute, Bucksburn, Aberdeenshire.

Assistant Lecturer (Grade B) in Electrical Engineering—The Registrar, Hatfield Technical College, Roe Green, Hatfield, Herts.

Assistant Works Manager (with honours degree in chemistry or chemical engineering, A.R.I.C., A.M.I.Chem.E., or equivalent) for Atomic Energy Factory at Salwick, Preston, to be responsible for operation of chemical plants—The Ministry of Supply, Division of Atomic Energy (Production), Risley, Warrington, Lancs, quoting Ref. 425.

Electrical or Mechanical Engineer (Scientific Officer grade) at the Royal Aircraft Establishment, Farnborough, for research and development in connexion with generation, conversion and control of electric power for aircraft—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting D.54/53A.

Lecturer in Chemistry, a Lecturer in Physics, a Lecturer in Mathematics, a Lecturer in Zoology and Botany, an Assistant for Geography and English, and an Assistant for Mathematics—The Principal, Adisadel College, Cape Coast, Gold Coast (by air mail).

Scientific Assistant, mainly to examine and abstract world scientific literature on grassland and field-crop research—The Director, Commonwealth Bureau of Pastures and Field Crops, Aberystwyth.

Scientists (M.A., M.Sc. or Ph.D. or equivalent in one of the physical sciences, mathematics, biomathematics, or mathematical economics, preferably with some industrial or laboratory research experience) for Operational Research and Systems Analysis—The Director, Research Personnel, Defence Research Board, Department of National Defence, 'A' Building, Ottawa, Canada.

## RESEARCH IN NATIONALIZED INDUSTRIES

IN one of its first studies, the Acton Society Trust expressed the opinion that parliamentary supervision of the nationalized industries in Great Britain is inadequate, and in a later study examined in some detail the use of the Parliamentary question. It is generally agreed that if the Parliamentary question were given free play over the whole field of activity of a nationalized industry, much of the advantage of a public corporation over a government department would be lost. To the extent to which some of the existing weaknesses of the nationalized industries are due to over-centralization, this is important; for Sir Henry Clay has shown convincingly how in practice real decentralization by a government department is impossible—the Minister cannot divest himself of the ultimate responsibility placed upon him by Parliament. The basic feature of the Parliamentary question is that it is answered by the Minister ultimately responsible for the decisions about which he is questioned.

The importance of the subject has been attested by the attention given to its broader aspects in recent books on British government. "British Government since 1918", for example, published in 1950, included a valuable contribution by the late Sir Arthur Street entitled "Quasi-Government Bodies since 1918", in which he sketched very clearly a number of the unsolved problems relating to the organization of public corporations, whether responsible for nationalized industry or not. More recently, in "Parliament: a Survey", Prof. A. L. Goodhart contributed a chapter on parliamentary control over the nationalized industries which, after reviewing recent Parliamentary and other discussions, endorsed much that Sir Arthur Salter wrote in his essay "The Crux of Nationalization", and concluded that up to the present no answer had been found to this major problem of control.

A Select Committee on Nationalized Industries was appointed in December 1951 to consider the present methods by which the House of Commons is informed of the affairs of the nationalized industries and to report what changes, having regard to the provisions laid down by Parliament in the relevant statutes, may be desirable in these methods, and its report is now available*. Whether Parliament has maintained an adequate control of the corporations is important and is also the one to which most attention has been directed. Whether Parliament has devised a method which, while allowing for adequate control, has provided a guarantee for the efficient management of these industries is, as Prof. Goodhardt rightly emphasizes, still more important. Nor do the Acton Society Trust studies suggest we are yet anywhere near finding an answer. It is, as Prof. Goodhardt remarks, a sobering reflexion that a major part of the economic life of Great Britain will soon be placed in the hands of a few comparatively unknown men who will be responsible for the efficient development of the fundamental industries; nor can we say whether it is possible to select men capable of solving the vast problems which attend the concentration of so much power in a few bodies.

---

* Report from the Select Committee on Nationalised Industries, together with the Proceedings of the Committee, Minutes of Evidence and Appendices. Pp. xxvi+140. (London: H.M. Stationery Office, 1952.) 6s. 6d. net.

In the April–June issue of 1950 of *The Political Quarterly*, a series of eight essays on aspects of nationalized industries in Great Britain were published. These have now been expanded and issued under the editorship of Prof. W. A. Robson in "Problems of Nationalized Industry"*. Six of the original essays are included in the present volume. That of D. N. Chester on the organization of the nationalized industries has been replaced by one by A. Albu on the same theme, and J. A. G. Griffith's essay "The Voice of the Consumer" is also discarded in favour of chapters by F. Milligan on "The Consumer's Interest" and "Public Relations in the Nationalized Industries". Six new essays include one on "Joint Consultation in Nationalized Industry" by A. M. F. Palmer, and one by Edmund Dews on "Scientific Research and Nationalized Industry". Prof. Robson contributes an introductory essay on the public corporation in Britain and also a comparison of nationalized industries in Britain and France, while the whole of the second part consists of general conclusions which he himself has drawn on the themes of the various essays constituting the first part.

Strong support is lent by these essays to the view that more general publicity regarding the work of the nationalized industries is desirable: some of the annual reports of the boards are severely handled. Generally speaking, however, it is not increased publicity in Parliament that is urged so much as effective use of such devices as the consumers' councils and an adequate system of public relations, both to secure the ventilating and remedying of grievances and the explanation to the public of the policy and operation of the boards.

The place of science and of scientific research in these industries requires closer consideration. Studies made by the Acton Society Trust and others have pointed to the difficulties which the scientist or technologist engaged in nationalized industries encounters and to conditions which may affect adversely the recruitment of men of the desired calibre. The recent Ridley Report, at least by implication, stressed the importance of research and its organization in nationalized industry and, as Mr. Dews reminds us in his chapter on scientific research and nationalized industry, the Advisory Council on Scientific Policy was asked so long ago as April 1947 to consider what should be the respective functions of Government departments, of the research councils and of outside bodies (including the boards of nationalized industries) in carrying out research.

The Advisory Council gave some attention to this problem in its first report and expressed the view that the executive department should be responsible for identifying problems requiring research, settling their order of priority, deciding where the various investigations should be carried out and applying their results. It is clear from the report that the boards of the nationalized industries are for this purpose regarded as executive departments, and to them likewise applies the Advisory Council's further recommendation that such departments require to employ scientific staffs corresponding approximately to the operational research units attached to the Service ministries and commands during the Second World War. The specific recommendation is made that departments should appoint a chief scientific officer to advise generally on the scientific aspects of departmental policy and, particularly, to define the problems calling for research, to arrange for its conduct and to watch the application of its results, and that this officer should be provided with an adequate scientific staff; this is in line with the comment of the Select Committee on Estimates in its third report for the session 1946–47 that a major weakness in the government organization for research and development was the absence of sufficient provision for the identification of scientific problems in day-to-day administration.

The Select Committee itself recommended the appointment of scientific officers or advisers, as the Advisory Council afterwards did, but it also recommended that such scientific advisers should stand high in the departmental hierarchy and should have direct access to the highest policy-forming level. Although it appears, from the review of government scientific organization in the civilian field which the Advisory Council on Scientific Policy issued in 1951, that there is sufficient contact between the chief scientific officers of the National Coal Board, the British Electricity Authority, the Gas Council, the Department of Scientific and Industrial Research and the Ministry of Fuel and Power, there would appear to be some reason to doubt whether this latter recommendation of the Select Committee has really been given effect in the nationalized industries. It is a question of status and the level at which science is able to affect policy.

This broad question of efficiency has not so far received attention from the Select Committee on Nationalized Industries, except from the negative aspect of the effect of the Parliamentary question on the management of these industries, and it would appear that managerial efficiency as such lies rather outside the terms of reference of that Committee. The minutes of evidence taken before the Select Committee scarcely suggest, however, that the Parliamentary question has adversely affected efficiency, though it clearly could do so if abused. Sir Hubert Houldsworth's evidence did not imply that, on the technical side, the danger is very real; but while he clearly recognized that the nation, as well as Parliament, has the right to be fully informed both as to general policy and the results of that policy, he looked to other means of providing such information—notably in the annual reports of the boards and in public debate on such reports.

Sir Hubert here made the important stipulation that such debate and discussion should be objective and constructive, proceeding not along political party lines but inspired by the desire to secure the highest standards of technical efficiency and public service. Prof. Robson, in the essays already mentioned, also recognizes the need for more impartial discussion and, particularly in commenting on Mr. Dews's essay, remarks on the need for a vigorous policy of research and development in the nationalized industries. He does not, however, like Mr. Dews, stress the need for new tests of efficiency and service, nor is it clear that he shares the view that, properly organized, an industrial research programme should be one of the means by which the nationalized industries can be kept under public review. To secure this, Mr. Dews points out, the research organization must be strong and active, in close touch with the industry and on friendly terms with it, yet independent enough to offer public criticism; and he thinks that a modified system of research associations is most likely to answer the purpose.

---

* Problems of Nationalized Industry. Edited by Prof. William A. Robson. Pp. 390. (London: George Allen and Unwin, Ltd., 1952.) 25s. net.

The question of the most appropriate organization of research is important—much more important than the exact means by which the necessary financial support is provided, subject to two conditions, both of which seem to escape both Prof. Robson and Mr. Dews. They seem prepared to admit that there is as yet little evidence that nationalization has provided the long-range outlook and the command of resources required for an effective research programme. Prof. Robson concedes also that we should not expect the public corporations to look very far ahead in the scientific sense, and that we should rely on the research associations rather than on the public corporations as sources of new knowledge and improved technology. Nevertheless, the responsibility for deciding expenditure on new ventures must rest with the boards: neither in nationalized nor in private enterprise can it wisely be entrusted to government departments.

Prof. Robson appears to be somewhat over-optimistic—particularly in view of the trend of recent questions in the House of Commons regarding public expenditure on scientific and industrial research—as to the freedom and independence which the research associations enjoy for the continuous and uninterrupted pursuit of long-range projects in fundamental or in applied science. More important, he, like Mr. Dews, has omitted the whole question of outlook to which Sir Henry Tizard directed attention in his Messel Memorial Lecture. Sir Henry Tizard was disturbed at the implications of a situation in which we are coming to rely increasingly on the State to finance developments for civilian purposes which formerly would have been financed by private enterprise.

Whether or not British industry is becoming less adventurous, it has to be admitted that financial conditions and taxation policy tend to discourage enterprise. It must also be admitted that there is little evidence that adventurousness is fostered by State control: quite apart from the high costs of the development stages, it is premature to claim that we have as yet entirely solved the problem of securing the continuous prosecution of long-range research where the financial resources are in the main provided by the State. The reports of the Advisory Council for Scientific and Industrial Research are not reassuring on this point, and it well merits further examination by the Advisory Council for Scientific Policy.

The most efficient and appropriate relations between the research organization in the nationalized industries and the relevant government departments and research associations, however, will fail to yield their full results unless the nationalized industries can attract scientific and technical staff of high quality. Against this possibility Mr. R. Lewis and Mr. A. Maude, in their recent book "Professional People", put a significant question mark. Difficulties do not arise so much from the conditions of service; rather they are inherent in nationalization itself and the consequence for the professional man of finding only one employer available for his talents. Prof. J. W. Cook, in an address to the Royal Institute of Chemistry some two years ago, noted the problem, but few besides Mr. Lewis and Mr. Maude have really faced the issue. Nevertheless, it is one that should figure prominently in discussing the organization of scientific research and development in the nationalized industries, and the wider question of the most appropriate organization of those industries to serve the needs of the day.

## SIR JOSEPH BANKS: 'THE FATHER OF AUSTRALIA'

### Sir Joseph Banks, K.B., P.R.S., the Autocrat of the Philosophers

By Dr. Hector Charles Cameron. Pp. xx+341+9 plates. (London: Batchworth Press, Ltd., 1952.) 25s. net.

CONSIDERING the immense impression that Sir Joseph Banks made on the science of his own time, he has been treated with singular unfriendliness by biographers and historians. The general conception of him that has come down to our time has been formed by his enemies. It is that of an overbearing tyrant, who ruled the Royal Society with a rod of iron for forty-two years, who blocked all access of scientific men to the Sovereign, who contributed nothing himself to the body of scientific knowledge, who belittled the achievements of those mathematically inclined, and who owed his commanding position mainly to his very great wealth. The well-known picture of him by Thomas Phillips that hangs in the rooms of the Royal Society has done something to reinforce this unfavourable view. It is right to remember that it was done when he was old, ill, gouty and unwieldy. We prefer to think of Sir Joshua Reynolds's picture of the gallant and intelligent young man whose eyes are seeing more clearly the vision of his childhood. Dr. H. C. Cameron's industry has excavated many new facts concerning the manly and not ungentle figure of this great man, and much of what he has to say places Banks in a new and very pleasing perspective.

Banks was little more than a child when he had a vision of what his life should be. It was to be devoted to the study of Nature and to the disposal of the results of that study for the public good. He was but a youth when he became sole controller of an immense fortune; but until the day of his death at seventy-six he never swerved from complete loyalty to his childhood's vision to which all his resources were completely devoted. His scientific writings are very few indeed; but there was scarcely any important scientific venture made in Britain during his adult years in which he did not play some direct or indirect part. He was truly the 'father of Australia', where alone full justice is done to his memory. Of British public institutions, Kew Gardens, the British Museum and the Royal and the Linnean Societies, among others, owe him an incalculable debt. In the "Age of Elegance" he was utterly indifferent to the calls of social gatherings unless science could be furthered thereby. He was as much at his ease in talking to gardeners as to the King, and there is every reason to believe that he and George III were sincerely attached to each other. During periods of George's mental alienation, his medical advisers found that nothing did the King so much good as a talk with Banks about plants, and this we may readily believe. He helped innumerable struggling, distressed and unfortunate men of science and their families and was not infrequently deceived by them. His scientific knowledge was prodigious. His personal courage was unquestioned and his honour was unspotted. If he made no great discoveries—and why should that be said of the man who explored the Pacific with Cook on the *Endeavour*?—he set a standard for all time of single-minded devotion to science.

Dr. Cameron has done a real service by throwing the clear light of documentary evidence on the career, acts and motives of this noble man. On putting down the book one feels that the shade of Banks has handsomely won a libel action which the living Banks would have been far too magnanimous to bring.

Charles Singer

# FORMATION OF SYMBOLS IN THE CHILD'S MIND

## Play, Dreams and Imitation in Childhood

By Prof. Jean Piaget. Translated by C. Gattegno and F. M. Hodgson. Pp. x+296. (London: William Heinemann, Ltd., in association with the New Education Fellowship, 1951.) 21*s*. net.

This translation of Prof. J. Piaget's "La Formation du Symbole chez l'Enfant" is the third of a trilogy devoted to mental development in the first years of life, and is largely based on the detailed study of three children. In the earlier volumes ("La Naissance de l'Intelligence chez l'Enfant" and "La Construction du Réel chez l'Enfant"), which are now being translated, the main theme was the development of sensori-motor intelligence at the pre-verbal level. This third volume deals in the main with the stage of 'representative thinking' which leads to reflective or operational thought proper. In 'representation' the child's mind goes beyond the present moment of time and the immediate space of the perceptual field. This is made possible by previous imitation and play, the former giving rise to images of successful adjustment and the latter to assimilated meanings of the environment. Representation is the union of the centrifugal images of imitation with the centripetal images of play. During the subsequent stage of 'operations', actions may be expressed by signs instead of being actually carried out. 'Operations' are possible actions reduced to anticipatory schemas, at the same time increasing the speed of thought and endowing it with the important characteristic of reversibility.

Each of these three phases, sensori-motor, representative and operational, is interpreted in terms of equilibria between assimilation of the environment and accommodation to it. They are progressive stages of adaptation. In assimilating the environment the organism preserves its cycle of processes, thus exemplifying a feed-back principle. In accommodating to the environment, the movements and positions of external objects act upon the movements and perception of the organism.

The first three chapters trace the development of imitation from reflex and sporadic beginnings through more systematic forms involving new audio-visual models to the stage of deferred imitation to an internal model. At the age of seven or eight there is imitation of detail, consciousness of imitation, and discrimination; but it is only imitation which is relevant to the child's needs.

The second part of the book discusses the beginnings of play and games and criticizes the various theories that have been advanced to explain ludic behaviour generally, though something of value is found in each of them. Prof. Piaget then develops his own theory of games. He distinguishes three aspects: practice games, symbolic games and games with rules. Children's games begin to decline when they are played according to rules. At that stage the transition to adult play begins. Just as symbolic games replace practice games when thought makes its appearance, so the symbol is replaced by the rule as soon as social relationships begin to be formed. Play is the converse and complement of imitation. In imitation there is primacy of accommodation over assimilation, whereas in play there is primacy of assimilation over accommodation.

The third part deals in detail with the development of cognitive representation: through the various stages from the earliest verbal schemas, 'preconcepts', and reasonings from particular to particular, to reversible operations.

The critic may feel that something is missing from Prof. Piaget's account, that something being the child himself in his chameleon-like activities and exuberant loves and hates. The child, it may be said, is more than an apparatus for answering the pointed questions of the investigator. But Prof. Piaget would be the last to claim that he is examining more than the cognitive life of the child. He has placed child development in the very forefront of psychology where it belongs, and his magnificent attempt to trace the emergence of logical structures from psychological ones will doubtless rank as one of the outstanding contributions to contemporary psychology.

The student of the history of scientific ideas will be interested in the resemblances which Prof. Piaget notes between the beginnings of rational thought in the child of seven or eight years and the scientific notions of the early Greek thinkers, who explained certain natural phenomena, for example, the origin of the stars, in terms of the identification of substances—stars being produced by air or clouds. He assumes that the same developmental mechanisms which account for the child's thought were characteristic of pre-Socratic thinking emerging from a mythological and pre-logical epoch.

"In spite of their trivial character, these examples are deserving of careful examination" (p. 218). This remark is in a way the keynote of the book and, indeed, of Prof. Piaget's work generally. Every remark or action of the child, even his first 'mummy' or 'bow-wow', is worthy of the most painstaking examination. It is on the analysis of the same material that Prof. Piaget has erected his imposing axiomatic system as described in his recent "Introduction à l'Épistemologie Génétique" (1950), an English translation of which is very much to be desired since it would provide the necessary stimulus for a wider discussion of this important work.

The translators of the present work deserve commendation for their excellent performance, which has won much praise from the author himself.

John Cohen

## THE PRACTICE OF SCIENTIFIC RESEARCH

### An Introduction to Scientific Research

By Prof. E. Bright Wilson, Jr. Pp. xiii+375. (London: McGraw-Hill Publishing Co., Ltd., 1952.) 51*s*.

THE title of Prof. E. Bright Wilson's book might suggest one of those works which, though they often stimulate discussion, have not been known to influence any actual research. On the contrary, the present book mainly comprises practical advice. After a short chapter more or less about why a scientist undertakes research, the second chapter gives some elements of the technique of an information service, that is, how to find, assemble and store the essentials of relevant prior work. The next chapter, on scientific method, is somewhat metaphysical; but it is sensible, not profound. The chapter on the design of experiments goes into more detail on subjects such as replication, factorial analysis and significance; but it tends to be discursive with brief common-sense observations on a number of topics which have a general connexion with how an experiment is approached. Under the headings of the design of apparatus and the execution of experiments, the author treats the elements of laboratory and workshop practice in scientific work. There are useful suggestions and interesting information; but the mixture is uneven, for the range of topics includes aphorisms about taking records and accessibility in the design of apparatus needing maintenance, fundamental matters such as the limitation of sensitivity by random fluctuation, and technological subjects such as closed control and amplifying systems.

The next four chapters, taking up nearly half the book, comprise a more systematic treatment of statistical principles and techniques, particularly for the assessment of significance. Some topics are included, such as confidence limits and quality control, which are of use more often in industrial studies. On the other hand, there is some formal logic at the beginning of the section, and it closes with the logical basis of probability theory, mentioning symbolic logic in passing. The author clearly attaches great importance to the assessment of the probability that a scientific conclusion is valid, and he explains what he means with care. The last three chapters return to the discursive style of the opening, with one or two notes on mathematical processes, a brief survey of modern aids to computation and hints on writing reports and papers.

The value of a book of this kind depends upon a judicious selection and treatment in the light of the needs of an important enough class of reader. It will not appeal to the experienced man of science, because it is too elementary and because there are too many important omissions in its lists of sources. Indeed, some remarks are so elementary that the student who needed to be told them would seem ill-advised to attempt a scientific career. Nevertheless, we must not forget that the vast expansion in scientific pursuits means that a great and increasing number of young scientific workers will lack the opportunity of acquiring a general knowledge of scientific endeavour and an appreciation of the realities of scientific research by direct contact with leading men of science. To those so placed, this book can be of value. They will realize that the life's work of a man of great ability and industry may be enshrined in a single sentence in a text-book. They will understand that, although a young scientist's research problem may seem very specialized, yet if he is to make a real advance he may have to call on a surprisingly wide range of knowledge and skill. This book can save the young scientific worker much unrewarding toil and inspire him to broaden his studies truly to fit himself for his calling.

S. Whitehead

## A TEXT-BOOK OF PRACTICAL BOTANY

### Textbook of Practical Botany

By Prof. R. C. McLean and Dr. W. R. Ivimey-Cook. Pp. xxiv+476. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1952.) 36*s*. net.

THE authors justify the appearance of this work, a companion volume to their "Textbook of Theoretical Botany", by pointing to the scarcity of practical text-books. It is written for "a general University course", which presumably means General B.Sc. standard, and how far such a book is needed at this stage is controversial. Ideally, at this level, the student should treat each exercise as an independent investigation, and in the main obtain the guidance he needs from standard works. By so doing he will learn his way about the literature and, at the same time, acquire a healthy independence of outlook. To work by this method alone would call for much more time than is normally available.

At the other extreme the student can be issued with schedules and instructions for all his practical work, but such 'cookery book' botany is far from ideal. In practice, some half-way measure seems to be indicated, and this is a part which the present book could fill. Very detailed instructions over the wide field which it covers are clearly out of the question in a book of fewer than five hundred pages, and there has been a good deal of careful selection so that parts of the syllabus which are not likely to be done in practical are omitted. Some of the sections are very short—variation (four pages), evidences for evolution (two pages), hybridization and inheritance (eight pages) and plant ecology, including soil analysis (nineteen pages). The student therefore could scarcely rely on this book alone, and more references to suitable literature might have been desirable. How far the book maintains a good balance must, of course, be a matter of opinion, and it would be unfair to criticize the allocations which the authors have made.

More serious is the criticism which must be made of inaccuracies and misleading or vague statements. A student might well have misgivings when he discovered that Fehling's test on a non-reducing sugar failed, although he had followed the instructions to the letter, for there are no directions that the solution should be neutralized after hydrolysis. The descriptions of *Pandorina*, *Volvox* and *Hæmatococcus* are not entirely accurate, while that of the dehiscence of a fern sporangium scarcely gives a good picture of the course of events. Transfusion tracheids are referred to as parenchyma; laburnum wood is not the happiest choice for tyloses; nor will the student find many chloroplasts in *Nostoc*; and it is surely time that meiosis lost its heterotypic and homotypic divisions. To expect a book of this type to be free from errors or to attain perfect lucidity would be unreasonable; but it does seem reasonable to ask if what might be regarded as a permissible margin—and the examples just noted are only a sample—has not been exceeded.

Nearly all the illustrations are from photographs, and they have been very sparingly used to illustrate material which is difficult to obtain or to prepare. As a whole, they are excellent and form an attractive feature of the book.

F. W. Jane

# MODERN THEORIES OF INTEGRATION

### The Lebesgue Integral

By J. C. Burkill. (Cambridge Tracts in Mathematics and Mathematical Physics, No. 40.) Pp. viii+87. (Cambridge: At the University Press, 1951.) 12*s.* 6*d.* net.

### The Theory of Functions of a Real Variable

By Prof. R. L. Jeffery. (Mathematical Expositions, No. 6.) Pp. xiii+232. (Toronto: University of Toronto Press; London: Oxford University Press, 1951.) 45*s.* net.

### Lezioni sulla teoria moderna dell' integrazione

Per Prof. Mauro Picone e Tullio Viola. (Manuali Einaudi, Serie di matematica.) Pp. 404. (Torino: Edizioni Scientifiche Einaudi, 1952.) 5,000 lire.

EVERY honours student of mathematics should know why Lebesgue's definition of an integral is preferable to the older definition due to Riemann. One of the easiest ways to acquire this knowledge is to study the clear and concise exposition of the subject by Dr. J. C. Burkill. The preface points out that by adopting Lebesgue's definition we can arrive quickly at results which otherwise require tiresome discussions. This general remark is illustrated by reference to a particular example. There are six chapters, entitled respectively sets of points; measure; the Lebesgue integral; differentiation and integration; further properties of the integral; and the Lebesgue–Stieltjes integral. The tract concludes with hints for the solution of all but the easiest of the fifty-five examples contained in various places, with more detailed solutions of the most important. Perhaps on some pages the virtue of conciseness has been carried to excess. For example, on pp. 7 and 11 there are results without proof, preceded by the statement "the reader will satisfy himself that . . ."; and on p. 10 the proof of a theorem concerning measure ends curtly with the words, "taking the limit, we have the general case". The table of contents is also too concise. For example, it does not reveal that the book contains the inequalities of Holder and Minkowski (pp. 65–66), and there is no index. But these are small defects in an excellent book.

A fuller treatment may be found in the book by Prof. R. L. Jeffery, which seems to consist of two distinct parts. The first part is for beginners in the subject, and starts with an introduction giving a brief account of the real number system. Then follow five chapters which may be described roughly as an amplified treatment of the corresponding chapters in Dr. Burkill's book. One novelty is that the treatment of measure is based upon Lebesgue's outer measure, which Prof. Jeffery prefers to call "metric of a set", and denotes by an unusual symbol. No use is made of inner measure, which he considers to be of purely historical interest. Another novelty is the inclusion of G. D. Birkhoff's ergodic theorem, which arose from problems in dynamics and statistical mechanics but is really a theorem in Lebesgue integration.

The second part of the book, which Prof. Jeffery himself considers of greater importance, consists of Chapters 6 and 7, entitled respectively the inversion of derivates, and derived numbers and derivates. These are written for more advanced students and aim at giving an exhaustive account of a subject to which the author has contributed by his own researches.

The last chapter, dealing with the Stieltjes integral, forms a sort of appendix to both parts. It starts with a simple account of the Riemann–Stieltjes integral and then proceeds to the more difficult topic of linear functionals and the recent ideas on measure and distribution due to L. Schwartz.

The book contains more than a hundred problems, a bibliography of seventy items, an index of subjects and an index of authors. It is carefully written in an attractive style.

The characteristic feature of the Italian book by Profs. M. Picone and T. Viola is the great emphasis on the Stieltjes integral. The introduction deals with two physical problems, the attraction of a body at an external point and the motion produced by an impulse. The first of these problems leads to an integral which involves elements of mass. Such integrals, in the light of modern physical views on the structure of matter, can be understood only as Stieltjes integrals. The authors then develop the whole theory of integration from this point of view, and introduce the term *massa elementare* for an additive function of finite variation. The word *massa* is used continually, roughly as often as the word *measure* in other treatises, but the word *misura* (measure) seems to occur very seldom. The early parts of the book make use of the original work on the theory of limits due to Prof. Picone. These opening chapters are rather different from those of other books, but later on we find the usual theorems, sometimes approached from an unusual angle. The advanced student will find this book interesting and valuable, containing many novelties which would require too much space to specify in detail. It concludes with four indexes, those of notations, of 'examples' (really applications of the theory), of authors, and of subjects. The style is readable, and the printing and paper are very good indeed.

## Lost City of the Incas

The Story of Machu Picchu and its Builders. By Hiram Bingham. Pp. 224+59 plates. (London: Phoenix House, Ltd., 1951.) 21*s*. net.

In the face of great physical difficulties, Dr. Hiram Bingham opened up the magnificent ruins of the late Inca city of Machu Picchu and made them generally known some forty years ago. He published a full account of his work shortly afterwards; but it is now out of print. He recently revisited the site, and this has impelled him to write a shortened popular account of it and of his work there. This is quite pleasant reading, and the photographs are good; but it would be easier to follow if the map had covered the whole of the area described and a plan of the ruins themselves had been provided.

In his original publication, Dr. Bingham put forward the theory that Machu Picchu was Tampu Tocco, the legendary ancestral home of the Incas, and suggested that it was reoccupied in late Inca times after being abandoned for many years. The reasons given for the earlier occupation were flimsy, and the archæological evidence pointed strongly to the late date of the site. No new evidence for an early occupation has come to light since, but Dr. Bingham again advances it in his new book. In general, this book betrays a neglect of recent archæological work in Peru, and a bad fault is the improper use of the term Inca to cover the whole span of ancient Peruvian civilization, which is calculated to give the impression that Machu Picchu is older than it really is.

## Synthesis of Electronic Computing and Control Circuits

By the Staff of the Computation Laboratory. (Annals of the Computation Laboratory of Harvard University, Vol. 27.) Pp. ix+278. (Cambridge, Mass.: Harvard University Press; London: Oxford University Press, 1951.) 52*s*. net.

The first part of this book is concerned with the procedure to be followed in the design of electronic circuits for performing complex binary switching operations such as are required in a digital computer. The principal problem is to arrive at a design which uses the minimum number of components. In 1938 C. E. Shannon showed how Boolean algebra could be applied to the analogous problem of the design of relay switching circuits. The present authors use a closely related method depending on ordinary algebraic manipulation to discuss the design of circuits using diodes, triodes and pentodes.

Tables are given which enable economical designs to be obtained in the case of circuits with up to four binary inputs, and one binary output. Advice is given as to how to proceed in more complicated cases, but, although the authors have clarified the problem to a considerable extent, it cannot be said that the advances they have made are fundamental in character.

The second part of the book contains an interesting chapter on the choice of a binary code to represent the ten decimal digits in a digital computer working in the scale of ten. Later chapters deal with the design of decimal adders, accumulators, multipliers, etc.

The book runs to more than two hundred pages (excluding tables), and the detailed discussion given, together with the large number of examples incorporated in the text, make it difficult on occasion to follow the main trend of the argument. The lack of an index is also a handicap. While everyone concerned with the design of binary switching-circuits should undoubtedly study this book, the reviewer feels that the authors would have made better propaganda for the use of their methods by publishing one or two separate papers in which the important features were explained concisely. The attention of readers may be directed to a group of papers published recently by Kalin, Burkhart and other members of the Harvard Computation Laboratory who were closely associated with the preparation of the book ("Proc. Assoc. for Computing Machinery, Pittsburgh Meeting": Richard Rimbach Associates, Pittsburgh, Pa., 1952). M. V. Wilkes

## Cooperation among Animals

With Human Implications. A revised and amplified edition of "The Social Life of Animals". By Prof. W. C. Allee. Pp. xv+233. (London: Sir Isaac Pitman and Sons, Ltd., 1951.) 21*s*. net.

This is a revised edition of a popular book on biology which is deservedly well known and highly appreciated in the United States. The main section of the work, which is much the same as in previous editions, does not require comment now; but the two last chapters, dealing with some implications of biology for human relations, contain much that is new. Here the author deals with the lessons biology has to teach mankind in connexion with such problems as population growth, food supplies and war. Such applications of biological knowledge to human problems are beset with pitfalls, as so many of the past *ex cathedra* statements of biologists have shown. Prof. W. C. Allee is sufficiently level-headed and critical never to fall into the error of assuming that human beings are just animals or that we can expect studies of *Drosophila*, white rats or chimpanzees to be directly applicable to human societies. His wise humanity and deep understanding of the nature of war and of some of the problems of human population and growth should do much to suppress those wild and muddle-headed theorizings which the less well-read biologist, however technically competent he may be, sometimes tries to convey to the long-suffering public. W. H. Thorpe

## New Biology, 13

Edited by M. L. Johnson and Michael Abercrombie. Pp. 128+19 plates. (Harmondsworth: Penguin Books, Ltd., 1952.) 2*s*.

In the thirteenth issue of "New Biology", which ably maintains the high standard of its forerunners, Prof. R. C. Oldfield contributes an interesting article in which he describes investigations into human skill which have been carried out at Cambridge and elsewhere during the past ten years. Another article, by H. Spurway, suggests that animals in captivity are not really at all representative of the wild populations from which they were originally drawn but are on the road to domestication. In an article on polyploidy and plant breeding, Dr. M. S. Swaminatham discusses some of the means of improving plants by multiplying the number of chromosomes they possess. Prof. E. J. W. Barrington's article on problems of thyroid function in vertebrates is an argument for a broad basis of comparison of different organisms as an aid to the understanding of any one. Dr. C. G. Johnson examines the bed-bug in its ecological relations to human beings.

# STORM DAMAGE TO WOODLANDS IN SCOTLAND ON JANUARY 31, 1953

By Prof. H. M. STEVEN
University of Aberdeen

THE storm on Saturday, January 31, 1953, caused widespread and serious damage to woodlands in the region of Scotland north of the River Tay and east of Inverness. This storm, which the day before had caused the sinking of the *Princess Victoria*, and on the evening of the same day was responsible for the flooding on the east coast of England and in the Low Countries, struck this region of Scotland during Saturday as the storm centre moved eastwards and south-eastwards along its track north of the mainland of Scotland.

## Meteorological Data

Data have been made available by the Meteorological Office for stations at Kinloss on the Moray Firth, Dyce near Aberdeen, and Leuchars in Fifeshire. From midnight on January 30–31, the direction of the wind changed slowly in the two more northerly stations from west-north-west to almost north in the afternoon. At the height of the storm about noon, it was between north-west and north-north-west. At Dyce the average hourly wind speeds increased from 9 m.p.h. for the hour ending 1 a.m. to 38 m.p.h. at 6 a.m., to 63 m.p.h. at noon. There was a slight decline thereafter, but the speeds remained high until evening. Gusts of more than 90 m.p.h. were recorded between 10 a.m. and 4 p.m.; the highest was 101 m.p.h. between 11 a.m. and 12 noon, with several greater than 92 m.p.h. during that period. At Kinloss, the pattern was similar, with higher speeds in the early hours, but the peak at the same period with gusts up to 98 m.p.h. At Leuchars, the speeds were less; the highest gust was 72 m.p.h. at 12.20 p.m. Most of the damage in woodlands took place between 10 a.m. and 2 p.m., when the winds were of hurricane force.

Wind-throw in woodlands often takes place when storms are preceded and accompanied by heavy rain, and the soils are water-logged and spongy. For example, this was so in the storm from the west on November 17, 1893, when a million and a half trees were blown down in Perthshire and Angus alone. The hurricane in New England, United States, on September 21, 1938, was also of this type, when gusts of more than 120 m.p.h. were recorded on the coasts, and in the week previously more than 9 in. of rain had fallen; the woodlands there still bear the mark of that disastrous storm. On this occasion, however, the rainfall in Scotland during January in the region affected had been less than normal at most stations, although the storm was accompanied by showers of rain and sleet.

The north-east of Scotland is less subject to exceptional storms than the western regions and the islands. Nevertheless, the woodlands have to withstand gales. For example, in Gold's records of highest wind gusts for the period 1909–35, speeds of 58 m.p.h. and more were recorded at Aberdeen in every year except 1921 and 1922. There have also been severe gales in recent years, for example on January 15, 1952. Some of these gales did damage to woodlands, particularly that on January 28, 1927, when a gust of 70 m.p.h. was recorded at Aberdeen; but the damage done by that and other gales in living memory was much less severe than in the recent storm.

## Damage to Woodlands

The type of damage caused by the storm of last January varies locally. In some woods the trees have been levelled as if a giant bulldozer had passed over them. From eye-witness accounts, it appears that this was caused by a series of gusts of hurricane force: the first bent the trees over; they rose up again, but succeeding gusts completed their over-throw—thus, in some instances, the trees lie in an unusually orderly way for storm damage. In others the damage is more selective and patchy and the stems may be tangled. In some woods there is little breakage of stems; in others, broken trees stand up among the blown.

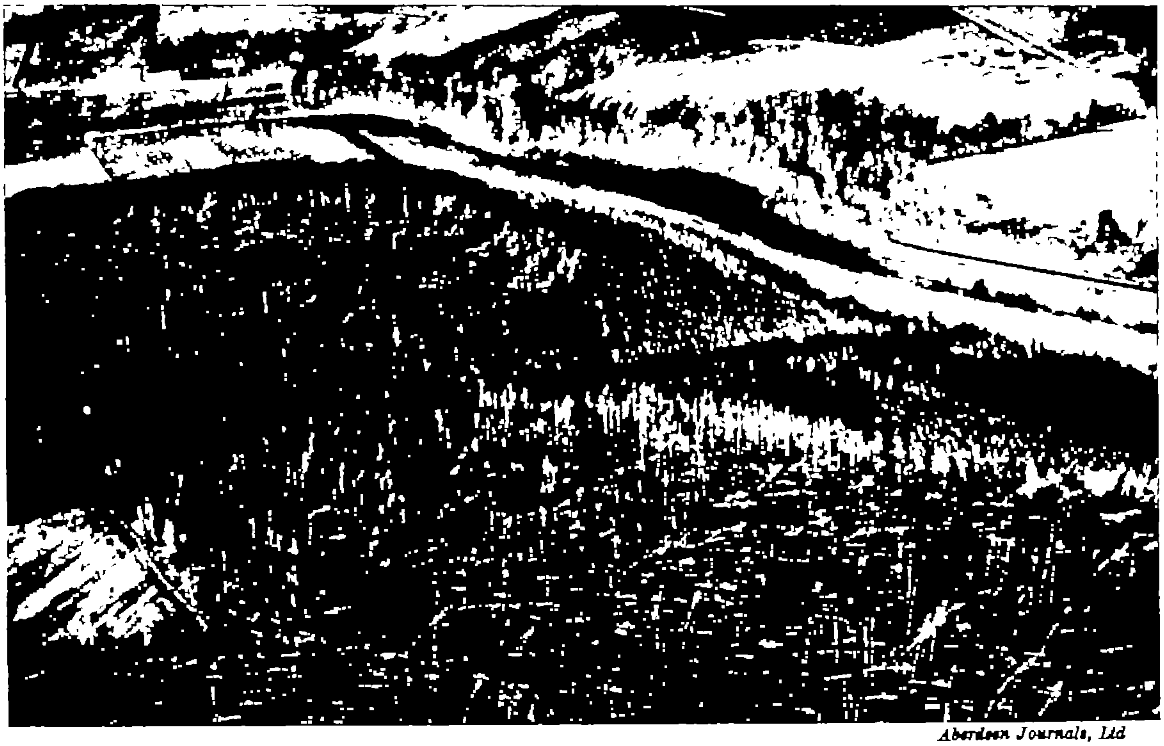
Immediately after the storm, officers of the Forestry Commission made a survey and obtained information from private woodland owners. It is estimated, provisionally, that about 35 million cubic feet of timber (more than one million tons) has been blown. Of this total, about 15 per cent is of broad-leaved species and the balance coniferous, mainly Scots pine. Approximately 90 per cent is on privately owned estates.

The amount of damage varies throughout the region. In the coastal strip north of Inverness, it is not serious. Greater damage has been done in the lowland regions of counties of Nairn, Moray and Banff, and the Spey Valley below Grantown-on-Spey. In the Upper Spey Valley it is somewhat less, particularly where the woodlands were sheltered by the higher land masses. Many of the woodlands in the lowlands of Aberdeenshire, the lower Dee and Don valleys and Kincardineshire have sustained catastrophic damage. In Upper Deeside, where sheltered by the Cairngorms, it is less severe. There is considerable damage to the woods of Angus; but as one proceeds southwards it decreases.

## Influence of Different Factors on the Damage

Where the effect of the storm has been catastrophic, it is not easy to discern the relative resistance of different tree species, the effect of soils, rooting, etc. It so happened that the influence of wind on forest stands was already under study in the Department of Forestry, University of Aberdeen, and a post-graduate worker immediately began a study of the effect of this storm, the Forestry Commission detailed a research officer, and the Macaulay Institute for Soil Research may study the correlation with soils. Until these and other studies are completed, only the broad patterns can be stated, and then only provisionally.

*Age and Height.* The clearest correlation is between the height of the stands and damage. Few woods less than 40 ft. in height have been damaged; it is thus the middle-aged and older woods that have suffered. It is difficult to believe that this is explained entirely by the known gradient of wind-speed with height above ground, and closer investigation is



*Aberdeen Journals, Ltd*

Middle-aged Scots pine in Carlogie Wood, Ballogie Estate, Aberdeenshire, after the storm damage on January 31. Photograph from the air

needed. This correlation is one reason why Forestry Commission woodlands have suffered relatively little damage, and that mainly in woods which they had acquired.

*Species.* Most of the woodlands in the region are coniferous, and Scots pine is the principal species. It is normally deep-rooting and is usually considered wind-firm. It has not proved so in this storm. In some, but not all, Scots pine woods, there is considerable breakage of stems at 6–12 ft. from the ground. European larch has shown greater resistance both to wind-throw and breakage; it has a more elastic stem and the timber is stronger. Both Norway and Sitka spruces have suffered wind-fall; but as they are shallow rooting and not considered wind-firm, one noted with surprise instances of greater resistance relative to pine. The same observation applies to Douglas fir.

Among broad-leaved species, beech is a common species in the lowlands of Angus, Aberdeenshire and the Moray Coast. Many of the trees are mature and over-mature, and the species has been considered, hitherto, as resistant to wind-throw. It has, however, suffered serious damage in this gale. It is even more surprising that the deep-rooting oak has also not proved wind-firm.

*Stocking.* In normal gale damage, there is often a correlation between damage and dense stocking. In woods where thinning has been neglected, the percentage of living crown is low and consequently the centre of gravity is higher than in woods thinned sufficiently early and regularly. This storm does not appear to have left such a pattern; but a closer study may reveal correlations with stocking.

*Physiography.* The factors comprised in this term are taken into account in planning forests and choosing species relative to wind risks. The effect of local shelter can be seen in this instance, but, perhaps, less clearly than usual. One point is noteworthy: many of the woodlands that suffered most severely were growing at low elevations.

*Soil Conditions.* Most of the soils in this region are derived from parent materials of glacial origin. It has been known for a long time that in this region there is often a compacted horizon which may be relatively near the surface, and which may impede the downward penetration of tree roots, either directly or through its influence on soil water relations. The upturned roots in many woods confirm this. Foresters have been aware of this problem. Indeed, more than a century ago, there are records of hand trenching to deal with it, and during the past twenty years, the deep ploughing on heaths carried out by the Forestry Commission and others has been done partly in the hope that depth of rooting would be increased. The opportunity will be taken, therefore, to investigate the connexion between wind-throw and soil conditions.

## Risk of Insect Epidemics

Because most of the blown timber is Scots pine, insect pests attacking this species are the potential menace. The pine weevil, *Hylobius abietis*, breeds in the stumps and roots of pine, and the adults attack young trees. It will be necessary to keep this pest under observation; but as many of the roots are exposed, and will dry quickly, it is not thought that populations will rise steeply. Indeed, at one time on some parts of the Continent 'pan felling', namely, winching the trees over, was practised to reduce the incidence of this pest.

The pine shoot beetles (*Myelophilus piniperda* and *M. minor*) are more likely to be a menace. Both breed under the bark of felled, dead and dying pine, and the adults tunnel into living shoots of the crown. The now abundant breeding material will almost certainly mean a rapid rise in populations, with consequential damage to adjoining crops. The pine, and especially the larger blown pine, should thus be salvaged first.

### Problems of Salvage

The timber blown would have had a value standing of more than £4,000,000. It is essential, therefore, that it should be salvaged before deterioration, alike in the national interest and that of the owners. As already stated, 90 per cent is privately owned, and if a substantial part of its standing value does not accrue to its owners, private forestry and the rehabilitation of private woodlands after the heavy war fellings will be prejudiced seriously in this region.

Largely through the enterprise of the public press, the importance of the problem of salvage is realized widely, and Ministers of the Crown in Parliament and elsewhere have given assurance of help. As soon as the first surveys were completed, the Chairman of the Forestry Commission, accompanied by the Director-General, went to Aberdeen and met the Forestry Commission Regional Advisory Committees for the East and North Conservancies of Scotland, consisting of representatives of private owners, timber merchants and others. The Conservator of the East Conservancy, Forestry Commission, has been put in general charge of the salvage operations, assisted by a small committee of representatives of the regional advisory committees, landowners' organizations and timber trade associations. It has been decided to aim at the completion of salvage within two years. Representatives of the home timber trade in Scotland estimate that there is sufficient sawmill capacity to enable this to be done. The necessary additional logging equipment can be got. Labour is likely to be the limiting factor, and plans are being worked out to obtain what is needed. The Forestry Commission has suspended the licensing of standing softwood timber for clear felling in Scotland, so that the resources of the timber trade can be concentrated on the blown timber.

Of the estimated 35 million cubic feet of timber blown, about 30 million is softwood from coniferous species, and 5 million of hardwoods from broad-leaved species. Of the softwoods, it is estimated that about 12 million will go into pitwood and the balance into sawn goods. The hardwood will produce sawn timber. The National Coal Board should be able to absorb the pitwood. The quantity of sawn softwood, although large, is less than 10 per cent of the annual consumption of this category in the United Kingdom; hence its absorption should not present serious difficulties, although unusually large quantities have been purchased overseas for delivery in 1953. The hardwoods consist principally of beech, and of a quality not suitable for high-grade use, but which could be sawn into railway sleepers and crossings. If the British railways revert temporarily to war-time practice and take this species for this purpose, it would be of assistance. The timber will have to be transported longer distances than normal, both for conversion, and later to consumers. Thus the question of railway-rates will be important in determining the prices obtained by owners of timber.

There are difficult problems still to be solved before the rapid and economic salvage of the blown timber is ensured, but none is insoluble. They must be solved if the effects of this disaster to forestry in the northern half of Scotland are to be mitigated by efficient salvage.

## RÔLE OF VITAMINS IN METABOLIC PROCESSES

THE Nutrition Society held a symposium on "The Rôle of Vitamins in Metabolic Processes" in the Biochemistry Department of the University of Sheffield on December 20, 1952. The conference was attended by more than a hundred and thirty members and guests, a number of whom took part in the discussions that followed the reading of the papers. The latter have been published in full in the *Proceedings of the Nutrition Society*.

In opening the meeting, Prof. H. A. Krebs (Biochemistry Department, Sheffield) said that the subjects of the papers had been chosen with the idea of concentrating attention on the recent advances in this field, and for this reason consideration of thiamine, riboflavin and nicotinamide had been excluded. During the first session, papers were read dealing with pantothenic acid, pyridoxin and vitamin $B_{12}$, substances which are growth factors for micro-organisms as well as for higher animals and which have been shown to have direct connexions with certain metabolic reactions. During the second session, the fat-soluble vitamins and vitamin C were considered; despite the existence of a considerable body of knowledge relating to the effects of their deficiency, comparatively little is known of the nature of their direct participation in metabolic processes.

Mr. D. E. Hughes (Medical Research Council Unit for Research in Cell Metabolism, Sheffield) showed how the bound forms of pantothenic acid, discovered through the use of micro-organisms for the assay of the vitamin, can now be seen to be various stages in the synthesis or breakdown of coenzyme A. The provisional structure assigned to this coenzyme incorporates a phosphorylated adenosine pyrophosphate and pantetheine, which is a peptide-like compound formed from pantothenic acid and mercaptoethylamine. The thiol group of the latter acts as a carrier of acyl groups in a variety of metabolic reactions. The oxidation of pyruvic acid, for example, results in the formation of acetyl coenzyme A, which may then react with oxaloacetate to give citric acid, thus furthering the oxidative metabolism of carbohydrate, or may contribute to the synthesis of a fatty-acid molecule. Succinyl coenzyme A, and probably other acylated forms of the coenzyme, may arise from other oxidative reactions and may serve in other synthetic reactions—for example, the synthesis of porphyrins.

The signs of pantothenic deficiency in the rat include striking changes in the adrenal cortex. Existing evidence might suggest that these arise, first, through an increased demand placed upon this part of the gland and, secondly, from a lack of ability to perform the synthesis of steroids as a consequence of a lack of coenzyme A. Many tissues, including the adrenal cortex, become depleted of coenzyme A when the diet is deficient in pantothenic acid, and the liver, which is the last to suffer depletion, shows a reduced capacity to acetylate sulphonamides. The greying of the fur and the secretion of porphyrin by the lachrymal glands may be secondary effects of the disturbance of adrenal functions.

Dr. H. M. Sinclair (Laboratory of Human Nutrition, Oxford) reviewed the characteristic signs of deficiency of pyridoxin in the rat, and in other animals. These include changes in the skin (erythema and œdema with superficial hyperkeratosis and atrophy of the transitional layers), a microcytic anæmia, and a characteristic gait with, occasionally, epileptiform fits, suggesting changes in the central nervous system. Increased vascularization of the skin in rats is not accompanied by vascularization of the cornea.

As with pantothenic acid, these signs of deficiency bear no simple relation to the known functions of the vitamin as a coenzyme. In the form of pyridoxal phosphate it is apparently concerned with the general metabolism of the amino-acids, as the coenzyme of transamination reactions. It is also required by bacteria for the breakdown of serine and cysteine, and the decarboxylation of certain other amino-acids; and for the synthesis of tryptophane by *Neurospora*. No satisfactory connexion can be established between the effects of deficiency of the vitamin and a lowered histaminase activity, as was suspected at one time.

Consideration of the possible connexions between these coenzyme functions and the changes in various tissues of the rat can go no further than speculation that protein synthesis is impaired, and that lesions appear where the tissues are most subjected to trauma and thus most need repair. This general connexion between the vitamin and protein metabolism is supported by observations on certain aspects of the protein metabolism of deficient animals.

Dr. J. W. G. Porter (National Institute for Research in Dairying, Reading) reviewed the many results suggesting that vitamin $B_{12}$, like folic acid, is concerned with the metabolism of one-carbon fragments, such as formyl and methyl groups, in animals and bacteria. In this case, however, the evidence does not extend to the identification of the vitamin as the coenzyme for a specific reaction. Methionine can partly replace vitamin $B_{12}$ in the nutritional requirements of rats and chicks, and can wholly replace it for certain mutants of *E. coli*. Thymidine has been reported to produce hæmatopoietic responses in man and the pig, and it can replace vitamin $B_{12}$ for the growth of *Lactobacillus leichmannii*. In both cases the explanation could be that the vitamin is required for the methylation of the normal precursors of these substances. These observations connect vitamin $B_{12}$ with protein and nucleic acid synthesis.

A possible clue to the form in which it functions lies in the presence in fæces of several forms of the vitamin, having different activities when tested on various organisms. At least five such forms are now known: of these, all are active towards *E. coli*, but two have little or no activity for *Lb. leichmannii*. All these forms have been found in small amounts in ox liver.

The presence of cobalt in the vitamin has provoked an investigation of its relation to cobalt deficiency in ruminants, and the most recent results indicate that doses of vitamin $B_{12}$ large in relation to those used to treat pernicious anæmia will cure the symptoms of cobalt deficiency in sheep.

Prof. C. P. H. Dam (Afdeling for Biokemi og Ernaering, Danmarks Tekniske Højskole, Copenhagen) was prevented from attending by illness, but his paper, entitled "Recent Studies on Vitamin K", was read for him. He outlined the relationship between vitamin K and blood coagulation, pointing out its complexity. The fact that the plasma from chicks treated with dicoumarol, or with coumachlor (a rodenticide: 3-(α-phenyl-β-acetylethyl)-4-hydroxycoumarin), shortens the prothrombin time of plasma from chicks deficient in vitamin K, and vice versa, shows that more than one coagulation factor is lacking in vitamin K deficiency; but mixing the two plasmas does not bring the prothrombin time to its normal value. There are differences between natural vitamin K and synthetic substitutes for it, such as menaphthone (2-methyl-1,4-naphthoquinone); the latter do not counteract the effects of administration of dicoumarol, and the natural vitamin gives a faster reduction of prothrombin time in chicks deficient in vitamin K. Prof. Dam thought it more likely that dicoumarol displaces vitamin K from an enzyme system than that it inhibits the synthesis of the vitamin. About 10 per cent of a dose of dicoumarol labelled with radioactive carbon was found in the liver after twenty-four hours. Simultaneous administration of a vitamin K substitute increased the rate of disappearance of the dicoumarol from the liver; the longer the dicoumarol was present in the liver the greater its effect on the prothrombin time.

There are natural variations in the clotting time of blood. A very extensive survey in Copenhagen has shown that for three days after birth there is a rise in the prothrombin time, which may be prevented by the administration of vitamin K to the mother *ante partum*, or to the infants. Irrespective of treatment, the (lower) adult level is not reached for six months. That hæmorrhages in the new-born cannot be entirely due to the increased prothrombin-time is indicated by the observation that there is a seasonal variation in the frequency of hæmorrhages, but not in the prothrombin time. Prof. Dam compared the observed decrease in mortality attributable to vitamin K therapy in Copenhagen, one per thousand births, with the extremes of optimism and pessimism attending its first discovery.

In reviewing the other fat-soluble vitamins, Dr. T. Moore (Dunn Nutritional Laboratory, Cambridge) began by pointing out certain differences between vitamins A, D and E. The daily doses for rats are, respectively, 0·025, 0·5 and 50 μgm.; and whereas the precursor of vitamin A, β-carotene, is readily converted to the vitamin in the body, the immediate precursor of vitamin D is formed in the body but cannot be converted to the active form without the aid of ultra-violet light. Vitamin A has a well-defined role in the cyclic formation of rhodopsin in the eye, and in some organisms this may be its sole function. However, in mammals only a minute fraction of the total vitamin A is present in the retina, and in deficiency of the vitamin characteristic changes are seen in the epithelial tissues, possibly due to the replacement of mucoproteins by keratin. In the vaginal epithelium the effects of œstrogens and vitamin A oppose one another, and excess of either may counteract the normal effects of the other. The metabolic reactions underlying these effects are unknown.

No detailed understanding of the action of vitamin D in promoting calcification exists; but some attempts have been made to substantiate the hypothesis that it acts directly on the conversion of phosphate from the organic to the inorganic form.

The observation that methylene blue can cure or prevent some of the symptoms of vitamin E deficiency, in particular the pigmentation of the uterus, suggests that vitamin E may have two functions in metabolism: one to serve as an intracellular anti-oxidant, the other a more specific one connected with reproduction. In vitamin E deficiency there are chemical changes in the muscles, including the depletion of creatine, and there is evidence of interference with protein metabolism. The red blood cells of rats deficient in vitamin E are hæmolysed by dialuric acid.

In the final paper, Dr. L. J. Harris (Dunn Nutritional Laboratory, Cambridge) examined the literature which, despite its bulk, still leaves us without evidence for a specific metabolic role of vitamin C. Among the older hypotheses was one associating ascorbic acid with collagen formation, and also the more general theory that certain formative cells, such as osteoblasts, show reduced activity; in these cells the vitamin has been found to be concentrated in the Golgi apparatus.

Recent studies have established that the metabolism of tyrosine is affected. The intact scorbutic animal (including man) fails to oxidize completely additional tyrosine fed to it, and tissue slices from deficient animals oxidize tyrosine less rapidly than normal.

The extent of conversion of folic acid into folinic acid is reduced in deficiency of the vitamin, a finding which might explain a suspected connexion between scurvy and anæmia.

The adrenal gland, the original source of Szent-Györgyi's 'hexuronic acid', contains high concentrations of the vitamin, and investigations are in progress to see whether any specific relation exists between the activity of the adrenal cortex and the function of the vitamin.

The great majority of animals can synthesize vitamin C, but, although glucose is known to be its precursor, it is still not known whether synthesis is a property of all cells of the body, or whether certain tissues are specialized for this purpose; similarly, the function of the vitamin in plants is still obscure.

J. S. D. Bacon

# ROYAL SOCIETY MOND LABORATORY, CAMBRIDGE

## By Dr. D. SHOENBERG

THE Royal Society Mond Laboratory was formally opened on February 3, 1933, by Mr. Stanley Baldwin, then Chancellor of the University. The twentieth anniversary of this occasion was recently celebrated by a party, preceded by demonstrations of phenomena at very low temperatures. In this brief review of the work of the Laboratory, it is appropriate first to recall how much it owes to the initiative and enthusiasm of Dr. P. Kapitza, who was its first director. Soon after Kapitza came to Cambridge in 1921, he became interested in measuring the curvature of α-ray tracks by magnetic fields, and this led him to think of the possibility of using magnetic fields much larger than those usually available in electromagnets but lasting for only a small fraction of a second. By limiting the duration of flow of a current in a coil to 1/100 sec., much higher currents can be used without producing too much heat, while at the same time 1/100 sec. is usually ample for the full establishment of any magnetic effect to be studied—thus, for example, an α-particle spends only about $10^{-9}$ sec. in the apparatus.

Kapitza first applied this principle in practice by discharging a specially designed accumulator battery through a coil, and breaking the current within a very short time of making by various automatic devices; by this means he studied α-ray curvatures, and later the Zeeman effect. The success of these preliminary experiments, in which fields of order 100,000 gauss were obtained, led him to think of more reliable methods of achieving still greater fields, and eventually he set up a large electric alternator which, during half a cycle of its operation, was connected across a coil to give a field of 300,000 gauss over a volume of several cubic centimetres. The equipment required considerable space, not only because of the large size of the machine and control gear, but also because, in order that the mechanical shock of the discharge should not disturb the delicate recording oscillographs, these had to be placed at a distance of about thirty yards away from the generator—a distance greater than that travelled by the shock wave in 1/100 sec. Space was provided on a site now occupied by the Department of Physical Chemistry, and Kapitza carried out a series of pioneer researches on various magnetic properties of matter—particularly the change of resistance of metals in a magnetic field, and also a study of magnetostriction and susceptibility. Many of the effects studied became much more striking at lower temperatures, and this led Kapitza to construct a hydrogen liquefier and to think of a helium liquefier in order to exploit more fully his high-field technique. It became clear that more laboratory space would be required to house such a complex of magnetic and cryogenic research, and the Royal Society made available funds from a bequest of Ludwig Mond in order to build a new laboratory suitable for the purpose, and at the same time appointed Kapitza to be Messel professor and director of this laboratory.

The special requirements of the Laboratory led to an unorthodox but attractive design of building, the central feature of which is a large hall for the high-field equipment, around which are grouped various smaller rooms for research and for the technical services (liquefiers, workshop and machine room); apart from some office accommodation and a conference room on an upper story at one end, the laboratory is mostly on one floor. The central hall later lost its primary function; but I think everyone who has worked in the Laboratory will agree that it has served a useful secondary function in lessening the isolation of the individual research rooms and providing a spacious atmosphere which is, perhaps, lacking in the more conventional type of laboratory built around narrow corridors.

As soon as the new Royal Society Mond Laboratory had been opened and the various machines installed, Kapitza set to work to build a helium liquefier. In characteristic style he preferred to design an entirely new type of machine rather than copy existing ones, and he was successful in developing a liquefier in which cooling below liquid-nitrogen temperatures was achieved by an expansion engine, and no liquid hydrogen was used (although, of course, liquid hydrogen was available from a separate liquefier if required for investigation at higher temperatures). It is interesting to note that Kapitza's machine was the forerunner of the Collins helium liquefier, which has become commercially available, and has been largely responsible for the enormous development of cryogenic research in the United States in recent years.

Just when it seemed that the Laboratory was ready to carry on full-scale research at low temperatures and high magnetic fields, a serious setback occurred when Kapitza was unable to return to Cambridge from a visit to the U.S.S.R. When it became clear that this situation was likely to continue, it was eventually decided to sell his high-field equipment to the U.S.S.R. so that Kapitza could carry on his work in Moscow, and to develop the Cambridge laboratory primarily as a cryogenic rather than a magnetic laboratory ; J. D. Cockcroft, who had been closely associated with Kapitza in much of his early work, was put in charge of the laboratory. Up to this time, cryogenic research at the temperatures made available by the use of liquid helium had been almost an exclusive monopoly of the Kamerlingh Onnes Laboratory at Leyden, though, on a smaller scale, work had been going on in Toronto, Berlin, one or two centres in the United States, and had just started in Oxford. A number of quite new and unexpected phenomena, such as superconductivity and the λ-transition in liquid helium, had been discovered in Leyden ; but these were, as yet, little understood, and there was still plenty of scope for relatively simple experiments designed to investigate points of principle.

During the next few years work, the policy of carrying out such experiments yielded handsome dividends. J. F. Allen and various collaborators (A. D. Misener, J. Reekie and E. Ganz) took up the study of the properties of liquid helium below the λ-point. Investigation of the anomalously high heat conductivity led to the discovery of the striking 'fountain effect', which showed that the heat flow was intimately associated with material flow. This was followed by the discovery that the liquid could flow in fine channels with an almost complete absence of viscosity, and this led eventually to the concept of a superfluid component of liquid helium. By a curious coincidence, Kapitza, in his new Moscow laboratory, had turned aside from his investigations at high magnetic fields and made the discovery of superfluidity in fine channels independently at the same time. D. Shoenberg took up various questions of the magnetic behaviour of superconductors which, following the discovery of the Meissner effect, were beginning to excite interest ; later, his studies of the magnetic susceptibility of small superconducting particles in mercury colloids, in parallel with experiments by E. T. S. Appleyard and others on superconducting thin films, proved the reality of the small depth of penetration (of order $10^{-5}$ cm.) of a magnetic field into a superconductor, which had been envisaged in the theory of F. and H. London, and demonstrated that this depth of penetration was strongly dependent upon temperature. At the same time, J. Ashmead had designed water-cooled coils to give steady fields of up to 50,000 gauss and used them in the development of the technique of adiabatic demagnetization, which had been recently opened up in Leyden and in Oxford, as a practical method of working at temperatures below 1° K.

All this work was interrupted by the Second World War, and for the next six years the Laboratory was turned over to various researches for the defence ministries. Late in 1945, cryogenic research was started again, first under Allen's direction, and since 1947, when Allen was appointed to the chair of natural philosophy at St. Andrews, under Shoenberg. Perhaps the most striking advance since the War has been the application, by A. B. Pippard, of the radar techniques developed during the War to problems of superconductivity. He has studied the behaviour of superconductors at very high frequencies—where the resistance is no longer zero, but drops only gradually as the temperature is lowered—and has developed methods of studying the depth of penetration which are not only more accurate than the colloid method and other 'static' methods developed in the Laboratory since the War but also lend themselves better to a variation of physical conditions such as crystal orientation and purity. These investigations have reached a stage where the London theory, which provided such a valuable interpretative guide in the past, is beginning to prove inadequate, and Pippard's results are indicating the direction in which the theory needs modification. Other researches on superconductivity by E. R. Andrew, T. E. Faber, J. M. Lock and D. Shoenberg have cleared up some of the puzzles connected with the intermediate state in the transition from the superconducting to the normal phase, and have enabled the magnitude of the surface tension between the phases to be estimated. New data have also been obtained by G. T. Pullan on the behaviour of the thermoelectric power in the transition and by J. K. Hulm and B. B. Goodman on the thermal conductivity of superconductors ; the adiabatic demagnetization technique is being used to extend the latter data into the range below 1° K., which is of particular interest theoretically.

A by-product of Pippard's work on superconductors has been his study of the anomalous skin effect in normal metals, which sets in when the electron mean free path becomes comparable with the skin depth—as occurs at very high frequencies and low temperatures. Pippard's semi-quantitative explanation of the effect was developed in detail by G. E. H. Reuter and E. H. Sondheimer, and comparison with the more detailed experiments later carried out by R. G. Chambers has provided new information about the parameters which enter into the electron theory of normal metals. The de Haas - van Alphen effect (a periodic variation of magnetic susceptibility with field strength) provides somewhat similar information, and during the past few years Shoenberg has discovered this effect in a number of metals. Quite recently he has developed a new method of studying the effect at high fields produced by discharging a large condenser through a coil, thus on a modest scale reviving the Kapitza tradition in the Laboratory.

Work with liquid helium since the War has been carried on by K. R. Atkins (now in charge of the Toronto cryogenic laboratory), D. V. Osborne, A. C. Hollis-Hallett and C. E. Chase. One of the most important researches has been the measurement of the speed of 'second sound' down to about 0·1° K., which proved to show just the rise predicted by Landau's theory. Other work has included studies of the helium film, the hydrodynamic properties of liquid helium and the absorption of sound. Rather as in superconductivity, here too, the further the experiments are pushed the more evident does it become that existing theories are in need of improvement.

In the course of all these researches the essential simplicity of experiments which was characteristic of the early days of the Laboratory has to some extent been lost with the necessity for more accurate measurements of less easily studied properties. More and more complicate devices have had to be accommodated in ever larger liquid-helium 'dewars', while at the same time the number of projects going on simultaneously has also increased. For these reasons the Kapitza liquefier which had rendered such excellent service for many years was abandoned in 1949, when Ashmead built a larger liquefier, working on the more conventional cascade principle, but yielding 3·7 litres per hour instead of the previous 1·8. This gain in yield was achieved by making use of the full capacity of the hydrogen and helium compressors of the Laboratory, and particular attention was paid in the design of the liquefier to ease of servicing. At present, as many as six or seven separate 'helium runs' can be carried on simultaneously on each of the two 'helium days' every week, and it is hoped that the flexibility of experimenting will be still further improved soon, when a large liquid-helium storage vessel is brought into use, so that it will be possible for liquid helium to be used at any time.

In such a brief account as this of twenty years work, it has been scarcely possible to do more than point out the main trends; and inevitably some of the individual researches—such as the experiments on paramagnetism before the War by H. M. Barkla and E. S. Shire, J. Ashmead and J. Reekie and more recently by C. G. B. Garrett—have found no mention. In its main lines of research, on superconductivity and liquid helium, the work of the Laboratory has helped in clarifying many tangled questions; but though in some ways it is now clearer what it is that has to be explained, the underlying fundamental theories are still far from developed. This is an attractive situation for the experimenter in the challenge it offers, and it is hoped that the Laboratory will play a part in the future in reaching the deeper understanding which is still lacking.

# NEWS and VIEWS

## Wool Textile Engineering at Leeds:
## Dr. Alfred H. Nissan

An interesting development in the Department of Textile Industries of the University of Leeds is the recent appointment of Dr. A. H. Nissan as the first holder of the research chair of wool textile engineering, which was endowed in 1947 by the Wool Industry Surplus Cloth Corporation and the National Wool Textile Export Corporation with donations amounting to £52,500. Dr. Nissan is a graduate in chemical engineering of the University of Birmingham; he was awarded the Sir John Cadman Medal and the Burgess Medal and Prize of the Institute of Petroleum. After carrying out research for the degree of Ph.D., he was appointed to the staff as lecturer in petroleum production engineering in 1939 and proceeded to the degree of D.Sc. in 1943. During the War he worked under the direction of Prof. F. H. Garner on flame-thrower problems, including the hydrodynamics of flow of complex visco-elastic systems and chemical engineering problems connected with the development of a novel flame-thrower fuel. In association with L. Grunberg, he also devised an interesting method of making sea-water potable by removing the chlorine ion with silver oxide and the sodium ion with uranium oxide. After the War, Dr. Nissan's attention was turned to combustion processes in diesel engines and the properties of detergent oils as lubricants, until he was appointed head of the Central Research Laboratories of the Bowater Paper Corporation, Ltd., in 1947. There he has had the interesting and satisfying experience of developing a strong and successful research team from the smallest beginnings; he should find equal opportunities in the work of the new chair to which he has been appointed.

## Imperial College of Tropical Agriculture:
## Dr. G. A. C. Herklots

Dr. G. A. C. Herklots, who is succeeding Mr. H. J. Page as principal of the Imperial College of Tropical Agriculture (see *Nature*, 170, 564; 1952), studied at Leeds and Cambridge under J. H. Priestley, Walter Garstang and F. F. Blackman. In 1928 he went to Hong Kong University to take charge of the new Department of Biology. His first interest in natural history found expression in the ten volumes of the "Hong Kong Naturalist" and in books on trees, orchids, natural history and birds. His interest then extended to economic products; and the *Journal* of the Hong Kong Fisheries Research Station, a book on food fishes, and another on vegetable cultivation, were the practical outcome. The problem of nutrition appealed to him, and he was fortunate in being seconded to Dr. B. S. Platt's nutrition survey unit in Nyasaland for six months in 1939. On his return to Hong Kong his services were lent to the Government, first in connexion with firewood supplies; later, as scientific adviser to the Food Controller, he helped in the establishment of a siege reserve for 1,800,000 people. Following forty-three months internment by the Japanese, when he had practical experience of poverty and malnutrition, he was entrusted with the task of re-organizing the fishing industry and organizing vegetable production on a large scale in Hong Kong. (Hong Kong now sells wholesale 30,000 tons of fish and more than 40,000 tons of locally produced vegetables annually.) As secretary for development he was responsible for the creation of a Department of Agriculture and for the administration of departments of gardens, forestry and of the fish and vegetable marketing organizations. Since 1948 he has been secretary for Colonial agricultural research at the Colonial Office—an appointment which has enabled him to visit most of the Colonies of the British Empire.

## Instruments and Accessories for Use with Radioactive Isotopes

The second edition has been published of "Instruments and Accessories for Radio-Isotope Applications", a useful brochure for the potential users of radioactive isotopes, edited by Dr. Denis Taylor and A. G. Peacock (pp. 20. London: Scientific Instrument Manufacturers' Research Association, 1952; free). Without detailed knowledge, the selection of suitable electronic equipment may be very difficult, and the details given of the various detector elements and associated equipment used for radioactive assay and radiation monitoring, together with the names and addresses of manufacturers, will therefore be of considerable assistance. The brochure is divided into sections, dealing with assay instruments, including Geiger, proportional, and scintillation counters, and ionization chambers; monitoring instruments; geological survey prospecting equipment; special instruments, including material-thicknesses gauges, pulse-amplitude analysers, D.C. amplifiers and oscilloscopes; and accessory equipment, covering isotope containers and handling equipment, laboratory furnishings and dry boxes, mass spectrometers and vacuum equipment. In addition to the Isotope Information Office of the Atomic Energy Research Establishment, from which details of the isotopes available, cost, method of delivery, etc., can be obtained, Isotope Developments, Ltd., (120 Moorgate, London, E.C.2) and Tracer Processes, Ltd., (385 Oxford Street, London, W.1) are listed as consultants on radioactive tracer techniques. Three books are recommended for further information on radioactive isotopes and counting-tubes.

### Physiology of Rubber Tapping

An attempt has been made by J. P. Riches and E. G. B. Gooding (*New Phytol.*, 51, No. 1, 1; 1952), and by E. G. B. Gooding (*ibid.*, 11), on the basis of work done at the Rubber Research Institute, Malaya, to give a more exact account of the forces at work and the processes involved when rubber trees are tapped for latex. The general conclusions of Arisz and Frey-Wyssling are retained in a modified form. When a trunk is first tapped, the latex is of high concentration and high viscosity. As a result of exudation at the cut surface, there is a fall in the internal pressure at the cut ends of the latex vessels; but, because of its resistance to movement, only a small amount of latex is forced out, and the drop in pressure extends over a short length of vessel only. Even though dilution takes place in the affected region, the concentration and viscosity of the latex are still so great as to offer resistance to its exudation. The resistance to movement of the latex has an effect similar to a positive turgor pressure: water is taken in slowly, and pressure release in distant parts of the vessel is delayed. Hence the slow exudation of only slightly diluted latex. These ideas are followed up in their application to subsequent tappings during which flow becomes easier, concentrations become lower, and the region affected by the exudation more extensive. Related aspects are also considered. In a further contribution (*ibid.*, 51, No. 2, 139; 1952), the effect of various factors on the concentration of latex is considered.

### Studies on the Lymnæidæ

In an extensive monograph entitled "Recent Lymnæidæ: their Variation, Morphology, Taxonomy, Nomenclature and Distribution", consisting of 223 pages, illustrated by 369 text-figures and 5 plates (Kungl. Svenska Vetenskab. Hand., Bd. 3, No. 1, 1951. Stockholm: Almquist and Wiksell; London: H. K. Lewis and Co., Ltd.; 25 kr.), Bengt Hubendick has reviewed the taxonomy and nomenclature and discussed critically the distribution of the living Lymnæidæ. As the result of a careful study of many examples of sixty-nine populations from different localities in Scandinavia, the author describes in Part 1 the variations, considered morphometrically, of the important species *Lymnæa peregra*. The range of variation disclosed in the shell and reproductive organs is truly remarkable and no doubt played its part in causing the author to become a 'lumper'. All too frequently collectors, having found a few specimens in a new locality which differ from the actual type in a few or some particulars, have erected a new species without pausing to consider the entire range of variation of the original population even in the type locality; they have also omitted to take into account the possibility or extent of ecophenotypical variations. In Part 2 of the monograph Mr. Hubendick passes on to discuss the value and applicability of morphological characters in the determination of species. In the course of this he has examined a wide specific range of material not only from the shell but also, wherever possible, by dissection and by serial sections of the male copulatory organs. Part 3 is a critical review of the recent Lymnæids considered under biogeographical regions in the light of the preceding mass of information. Finally, a bibliographical list of the previously recorded Lymnæidæ is provided, excluding the specialized Lancinæ, which includes a number of genera and about a thousand specific names. These the author has reduced to three genera and forty species with a number of varieties. This work will remain indispensable to workers in the field for many years.

### Pocket Check List of Malayan Timber Trees

In *Malayan Forest Records*, No. 17, Mr. J. Wyatt-Smith has prepared a "Pocket Check List of Timber Trees" for use by Malayan forest officers (pp. 716: Kuala Lumpur: Forest Department, 1952; 3 Malay dollars or 7*s.* 6*d.*). The list includes all trees which reach timber size, fixed arbitrarily at 4 ft. in girth at breast height. A limited number of common small trees, although they do not reach timber height, are included as being of importance in providing poles and firewood used locally. This publication does not suffer from the disadvantage that attends many other forestry manuals of being too bulky to be taken out into the field. Indeed, this small volume is intended as a book of reference, and its regular use should ensure that only preferred vernacular names are employed and correct symbols used for enumeration surveys and linear sampling. The book is divided into four parts as follows: list of Dipterocarps; list of non-Dipterocarps; alphabetical index to scientific names of all trees included in Parts 1 and 2; keys to groups and species of Dipterocarps. An interesting addition is a translation into Malay of the introductory notes to Parts 1 and 2 for the benefit of the Malay field staff of the Department of Forestry.

### Housing in the Tropics

The problem of low-cost housing in tropical areas is the main topic of the sixth bulletin in the series on Town and Country Planning published by the United Nations Department of Social Affairs. The bulletin states that the great majority of dwellings in the villages, town and cities of the tropics are woefully deficient in the essential physical and social requirements of shelter. Overcrowded, structurally unsound, insanitary and infested with vermin, they lack the simplest arrangements for cooking and storing food or for washing; they are far removed from the most modest concept of standards of legally established minima. The bulletin also presents articles on design and construction for tropical housing, suggestions for improving sanitation in tropical areas and examples of how numerous communities have achieved better housing through 'self-help' projects. International activities in the field of tropical housing are reviewed in a section covering actions taken by the United Nations and several Specialized Agencies, technical assistance given by the United Nations and other organizations, and housing discussions at recent international or regional conferences.

### Manchester Public Libraries: Annual Report for 1951–52

The hundredth annual report of the Manchester Public Libraries Committee, covering the year ended

March 31, 1952 (pp. 55+10 pl.; Manchester: Central Library, 1952), records a slight decrease in the total issue of nearly six million volumes, continuing the trend in the adult lending libraries since the general increase in the cost of books enforced a reduction in the purchase of several copies of a popular book. The photographic reproduction service is in such demand that many requests from beyond the confines of the City have had to be declined. The value of this service has been demonstrated most effectively in the Technical Library, which has its own photographic equipment. The report indicates the way in which this Library is being developed in the closest possible liaison with the various specialist libraries and industrial organizations, and the value of such technical library service is now becoming recognized by industrial firms. Its seating capacity is taxed to the utmost, and although the total issue of items was 186,095 compared with 186,014 in the previous year, the number of books issued on request at the counter again increased in all subjects, especially in technology. The trade catalogue collection now exceeds ten thousand items, nearly six thousand of which were consulted during the year—an increase of 50 per cent. Stress is laid on the assistance given to readers by the staff of both the Technical Library and the Commercial Library and Information Department. In view of the approaching centenary of the Manchester Public Libraries, a chronological table from the purchase of the first building, the Hall of Science, Campfield, on June 10, 1850, is included with the report.

## Large-volume Measuring-Flasks

Messrs. H. J. Elliott, Ltd., E-Mil Works, Treforest Trading Estate, Nr. Pontypridd, Glam., state that from time to time they receive inquiries from laboratories in Great Britain and abroad for measuring-flasks of 3, 5 and 10 litres capacity; the maximum capacity generally available is only 2 litres. Their present information is that the demand would be limited to about a dozen of each size per annum, which would scarcely justify the expense of obtaining the necessary moulds. Scientific workers interested are invited to write to Messrs. H. J. Elliott, to assist the firm in deciding whether to undertake the production of measuring-flasks of large capacity.

## Nuffield Foundation Gerontological Research Fellowship

The Nuffield Foundation, as part of its programme for the care of old people, is offering a research fellowship, of professorial status, for research on the scientific aspects of ageing, or alternatively one or more fellowships of less senior status. The award(s) may be tenable at any university in the United Kingdom and is open to applicants of either sex, usually not more than forty-five years of age. The senior fellowship will normally be made for a period of five years, renewable for five more years, and will be worth not less than £2,000 a year plus superannuation and child allowance; research expenses will be met by the Foundation, including provision for research assistants, apparatus and technicians. If, instead of this appointment, one or more fellowships of a lower category are awarded, they will be for three years in the first instance and worth £1,000–£1,500 a year plus superannuation, child allowance and research expenses. Application forms, to be returned before June 1, and further information can be obtained from the Secretary, Nuffield Foundation, Nuffield Lodge, Regent's Park, London, N.W.1.

## Sixth International Congress of Microbiology

The Sixth International Congress of Microbiology will be held in Rome during September 6–12, 1953, under the presidency of Prof. V. Puntoni, director of the Institute of Hygiene, University of Rome, with Prof. E. Biocca, director of the Institute of Parasitology, University of Rome, as secretary-general. The following is a provisional list of the sections into which the Congress will be divided: general microbiology (morphology, metabolism, growth factors, etc.); growth inhibitors (antibiotics, chemotherapeutics, antiseptics); genetics; pathogenicity (virulence, toxins); microbiological technique and diagnosis (large-scale production of micro-organisms, quantitative microbiology, etc.); general immunology; immunological chemistry; animal viruses; plant viruses; bacteriophages; rickettsiæ; schizomycetes; spirochætes; fungi; protozoa; microbe-transmitting arthropods; microbiology applied to human, veterinary and plant pathology; microbiology applied to agriculture; industrial microbiology and fermentations; microbiology applied to hygiene; and microbiology of milk and foodstuffs. Since the preliminary programme was prepared, the Organizing Committee has decided to establish a sub-section on bacterial taxonomy. All those wishing to read papers must send in titles and abstracts (not exceeding five hundred words) before April 30. In connexion with the Congress the Istituto Superiore di Sanità is planning six symposia, at which the lectures will be by invitation only. The symposia will be on the following subjects: bacterial cytology; microbial metabolism; nutrition and growth factors; growth inhibitors and chemotherapy; morphology, biology and systematics of the Actinomycetales; and host-virus interactions. Further information can be obtained from the VI Congresso Internazionale di Microbiologia, Istituto d'Igiene "G. Sanarelli", Città Universitaria, Roma.

## Faraday Society: Fiftieth Anniversary and Hundredth General Discussion

The fiftieth anniversary celebrations and the one hundredth general discussion of the Faraday Society will be held in the Royal Institution (21 Albemarle Street, London, W.1) during April 16–18 under the presidency of Prof. H. S. Taylor, dean of the Graduate School, Princeton University. The programme for April 16 will consist of addresses by two founder-members, Prof. F. G. Donnan and Sir James Swinburne; an address by Sir Harold Hartley on "Michael Faraday as a Physical Chemist"; the seventh Spiers Memorial Lecture, on "Models and Molecules", by Prof. J. H. Hildebrand (University of California); and a guest-night dinner at the Dorchester Hotel to commemorate the fiftieth anniversary of the Society. During April 17–18 there will be a general discussion on "Equilibrium Properties of Solutions of Non-Electrolytes", in which the equilibrium properties of liquid mixtures (general theory and experimental) and solubility (gaseous mixtures and liquid mixtures) will be considered. Application for attendance at these meetings must be made by March 22. Application forms and further information can be obtained from the Secretary of the Society, 6 Gray's Inn Square, London, W.C.1.

## Third International Biometric Conference

The third international biometric conference, arranged by the Biometric Society, a Section of the International Union of Biological Sciences, will be held at Bellagio, on Lake Como, during September 1–5. There will be ten half-day sessions on the following subjects: training in biometry, mathematical problems in genetics, industrial applications of experimental designs, agricultural designs, public health and social medicine, biological assay with special reference to immunology, biometrical problems in ecology, functional relations in experimentation, methodological problems in biometry, and sequential experimentation. In order to save time, communications from members may be presented in the form of exhibits of mounted charts, photographs, etc. Full information concerning each contributed paper or exhibit, including a summary in English of not more than two hundred words, should reach the secretary of the conference (Dr. L. L. Cavalli-Sforza, Istituto Sieroterapico Milanese, Via Darwin 20, Milano) before April 30, from whom all further particulars can be obtained.

### Ionization Phenomena in Discharges: Conference in Oxford

The Clarendon Laboratory, Oxford, in co-operation with the Institute of Physics, the Physical Society and the British Electrical and Allied Industries Research Association, will be holding a conference on "Ionization Phenomena in Discharges" during July 18–23. Visits to laboratories, social meetings and excursions have been arranged for July 18–19, and then the main subjects will be discussed as follows: July 20–21, the mechanisms of glow discharges, sparks and arcs, and electrodeless discharges; July 22–23, Geiger counters, photo-ionization processes and ionization by electron collision in gases. A session will be reserved for questions of general interest. Further particulars can be obtained from the secretary of the Conference, Dr. G. Francis, Clarendon Laboratory, Oxford.

### British Sociological Association

The first conference of the British Sociological Association, to be preceded by the annual general meeting, will be held at Queen Elizabeth College, Campden Hill Road, London, W.8, during March 27–29. The topic of the conference will be "Social Policy and the Social Sciences". The address at the first session will be given by Prof. Gunnar Myrdal, executive secretary of the Economic Commission for Europe. The conference will divide into three groups to discuss: (1) health; (2) design and planning; (3) needs and standards in the social sciences. Reports from the groups will be presented and then summed up by Prof. T. H. Marshall. Further information can be obtained from the honorary general secretary, R. J. Goodman, British Sociological Association, Skepper House, 13 Endsleigh Street, London, W.C.1.

### Radio Industry Council Awards for Technical Writing

The Radio Industry Council has awarded six premiums for technical writing in the field of radio, the articles being published during 1952. These premiums, of which the first four are for twenty-five guineas and the other two for ten guineas, have been awarded to the following, the name of the journal and subject of the article being shown in brackets: P. H. Parkin and J. H. Taylor (*Wireless World*: speech reinforcement in St. Paul's Cathedral); T. Somerville and C. L. S. Gilford (*B.B.C. Quarterly*: composite cathode-ray oscillograph displays of acoustic phenomena and their interpretation); J. A. Jenkins and R. A. Chippendale (*Electronic Engineering*: some new image-converter tubes); W. R. Stamp (*Discovery*: underwater television); T. W. Bennington (*Wireless World*: propagation of very high frequency radiation via sporadic E); and Dr. G. N. Patchett (*Wireless World*: faulty interlacing). The awards will be presented at a luncheon of the public relations committee of the Council at the Café Royal, Regent Street, London, W.1, on April 9.

### Announcements

Mr. Walter English, director and general manager of Messrs. Brough, Nicholson and Hall, Ltd., Leek, has been awarded the Textile Institute Medal, in recognition of his distinguished services to the textile industry in general and to the Institute in particular.

A symposium on some present problems in virology, to be conducted in French and English, will be held in Lausanne by the Centre de Collections de Types Microbiens de l'Institut d'Hygiène et de Bactériologie during May 22–23. The fee for the meeting is 15 Swiss francs. Enrolment forms and further information can be obtained from Prof. P. Hauduroy, 19 rue César Roux, Lausanne.

A symposium on cortisone and the suprarenal cortex, organized by the University of Milan and sponsored by the Società Italiana di Reumatologia, will be held in Milan during August 31–September 2. Short papers, lasting not more than twenty minutes, on the biological and clinical aspects of the topic will be read, the permitted languages being Italian, French and English. Further information can be obtained from the secretary of the symposium, Prof. C. B. Ballabio, Clinica Medica dell'Università di Milano, via F. Sforza 35, Milano.

The seventh annual conference of the Stress Analysis Group of the Institute of Physics will be held in the Engineering Laboratory, University of Cambridge, during March 25–27. Further information can be obtained from the honorary secretary of the Group, E. K. Frankl, Engineering Laboratory, Trumpington Street, Cambridge.

The laboratories of the British Non-Ferrous Metals Research Association (81–91 Euston Street, London, N.W.1) will be open for inspection, by invitation only, on March 23 at 3 p.m.

A special exhibition, entitled "Navigation To-day", will be opened by Lord Waverley at the Science Museum (South Kensington, London, S.W.7) on March 31 at 3 p.m. The exhibition will be open to the public until the middle of September; during the course of this time six special evening lectures on various aspects of navigation will be given. Features of the exhibition will be full-size models of a ship's bridge and of the flight deck of an aircraft.

The fifth technical trade exhibition of raw materials and equipment used in the paint, varnish and printing-ink industries, organized by the London Section of the Oil and Colour Chemists' Association, will be held at Borough Polytechnic, Borough Road, London, S.E.1, during March 30–April 1 (2.30–8.30 p.m. each day). Further information can be obtained from the honorary secretary, H. C. Worsdall, c/o Plastanol, Ltd., Crabtree Manor Way, Belvedere, Kent.

Referring to the review of the "Proceedings of the Second Berkeley Symposium on Mathematical Statistics and Probability", published in *Nature* of March 7, p. 410, the Cambridge University Press states that the English price is £4 2*s.* 6*d.*

# HÆMOGLOBIN METABOLISM

A SYMPOSIUM on hæmoglobin metabolism, under the chairmanship of Prof. G. Payling Wright, was held in London on the evening of February 17 by the Section of Pathology of the Royal Society of Medicine. Dr. A. Neuberger was prevented by illness from giving the opening paper, which was on hæm biosynthesis, and his place was therefore taken by Mr. John Scott. Mr. Scott referred to the important work of Shemin and Rittenburg, who were the first to show that glycine is the specific precursor of porphyrin nitrogen. They also showed that the incorporation of nitrogen-15 into hæmoglobin after feeding such nitrogen-labelled glycine to a man revealed that the hæmoglobin of red cells is not continuously degraded and synthesized like other proteins, but has a life-span of about a hundred and thirty days. Certain limitations, inherent in isotope experiments, together with the delay in the delivery into the circulation of hæmoglobin after synthesis of the porphyrin in man, render difficult the interpretation of the persistence of small quantities of isotope in the red cells even two hundred and fifty days after the feeding of glycine. In contrast, the Ashby agglutination technique appears to show that no appreciable number of red cells survive for more than a hundred and thirty days. While this might be due to the synthesis of porphyrin from glycine retaining a low but definite isotope-content for as long as a hundred days, it is not impossible that there is some re-utilization of hæmoglobin or hæm from the cells breaking down. Experiments by Shemin *et al.*, and by Muir and Neuberger, using glycine and acetate labelled in various ways by nitrogen-15 and carbon-14, have shown that all the atoms of the protoporphyrin molecule can be accounted for in terms of glycine and a four-carbon compound, such as succinic acid, derived from acetate by the Krebs tricarboxylic acid cycle. The experimental evidence is in accord with the initial synthesis of a monopyrrolic unit bearing a carboxyethyl and a carboxymethyl group in the β positions. Condensation of four of these units under the restricted conditions postulated by Neuberger, Muir and Gray would lead to the formation of uroporphyrins I and III, the latter in excess. Decarboxylation of the carboxymethyl group of these would lead to coproporphyrins I and III; an oxidative decarboxylation of two of the carbethoxy groups of this last porphyrin would lead to protoporphyrin IX.

Prof. C. Rimington emphasized the enormous synthetic capacity of the hæmopoietic system. Whipple has stressed the great importance of the liver and labile protein reserve in meeting emergencies for the production of fresh red cells and hæmoglobin by the hæmopoietic organs. Reference was made to the stimulating effect of amino-acids in hæmoglobin regeneration after hæmorrhage. Borsook has observed that the incorporation of some amino-acids labelled with carbon-14 into the hæmoglobin and stroma of reticulocytes from phenylhydrazine-treated rabbits is always greater when the maturation is studied in a plasma medium rather than in saline. This effect is in part due to some unidentified factor present in plasma. Thorell has shown that the total protein in bone marrow cells has reached a maximum, and the ribonucleic acid content, which is always correlated with protein synthesis, has fallen to a very low level by the time hæm production is occurring. Although this suggests that globin is formed before the hæm, the microspectrographic method used does not discriminate between globin and other proteins. *In vivo* and *in vitro* exposure to X-rays affects the synthesis of hæm and globin to a different extent, and also suggests that the two processes are independent. Muir, Neuberger and Peronne have shown that, when glycine labelled with carbon-14 is fed to the rabbit, the glycine of the globin and of the hæm are of comparable radioactivity only after twenty-four hours. Before this time, more activity was in the globin glycine. This could be due to globin formation preceding hæm formation or to the relative sizes of the globin and porphyrin pools and other factors. Hæmoglobin synthesis may also be studied in hæmolysates of avian nucleated red cells, and much valuable information may in future be obtained from such a system.

Dr. W. M. Davidson described the structure of the red cell with its preferential barrier to diffusion, and was of the opinion that, at the end of its life-span, certain enzymes become used up so that the cells are destroyed by the reticulo-endothelial system. Lytic processes play a major part in certain disorders, but probably not in normal red cell destruction. Lysis can be effected by certain chemicals, antibodies, hypotonic solutions, heat, freezing, buffeting, alteration in *p*H and the effects of light especially in the presence of photosensitizing agents, such as porphyrins, Rose Bengal, etc. Cells which have been partly damaged by some lysins or are congenitally fragile lyse in slightly hypotonic solution. Ionic surface-active lysins penetrate monolayers of cholesterol and lecithin, substances known to be important constituents of the cell structure, and raise the surface pressure until collapse occurs. The relationship of non-ionic agents to hæmolysis is less clear. Sphering appears to be an important but not essential preliminary to lysis, and the process, though reversible in its early stage, soon becomes irreversible. Serial estimations of the diameters of red cells show the process of development and disappearance of the spherocytes. Lysis is sometimes preceded by agglutination, the formation of siderocytes, Heinz bodies or basophil stippling. It is probable that the hæmolytic activity of bile salts, which are present in circulating blood, is normally prevented by certain inhibitors. In most immune hæmolytic reactions, a factor sensitizes the red cells for the lytic agent which is usually complement. Some hæmolysins cause only agglutination *in vitro*, but hæmolysis *in vivo*; and some incomplete antibodies have no apparent effect on red cells *in vitro*, but cause hæmolysis *in vivo*. Human hæmolytic disorders are classified according to whether the cells of the affected person have, or have not, a shortened life after transfer into normal individuals. There is a definite difference between *in vitro* and *in vivo* effects of the immune hæmolysins; *in vivo*, some factor, possibly a tissue lysin, greatly exaggerates the reaction.

According to Prof. C. H. Gray, the mechanism of breakdown of hæmoglobin to bile pigment is obscure. The original view was that the globin is split from the hæmoglobin molecule to give hæmatin, which is then broken down through protoporphyrin to bile pigment. Earlier workers who attempted to demonstrate the conversion of hæmatin to bile pigment obtained discordant results, but in 1950 London showed by isotope experiments that at least 20 per cent of administered hæmatin is rapidly metabolized to bile pigment. Although the experiments of Grinstein and his colleagues indicate that part of the fæcal protoporphyrin in the dog may be formed from breakdown of hæmoglobin, in man porphyrin excretion can contribute no more than an insignificant amount to the total breakdown products of hæmoglobin. Lemberg has shown that hæmoglobin is oxidized by oxygen in the presence of ascorbic acid to choleglobin, a complex of globin and the iron derivative of a bile pigment. The proportion of the total hæmoglobin broken down by intra-corpuscular degradation of this kind is quite unknown. It seems likely that the dipyrrolic compounds, such as propentdyopents and bilifuscins, are derived from bile pigments subsequent to their excretion by the liver. Isotope experiments have shown that bile pigment can arise not only from cells at the end of a normal life-span, but also by a very rapid mechanism as well as by a slower mechanism not from cells at the end of a normal life-span. In the small intestine, the bilirubin excreted in the bile is reduced to 'fæcal urobilinogen', a mixture of colourless precursors of the pigments stercobilin, urobilin IXα and *d*-urobilin. Baumgartel believes that mesobilirubinogen, the precursor of the optically inactive urobilin IXα, is formed only in the liver, but Watson has contested this view. The determination of fæcal urobilinogen has been much used as a rough measure of hæmoglobin breakdown. Interpretation of the results obtained must, however, always take into account certain limitations: urobilin and urobilinogen are converted into other substances not estimated by the Ehrlich reaction; and hæmoglobin may break down directly into dipyrrolic compounds, or other unknown substances. The very high proportion of bile pigment not formed from old red cells may occur in other diseases as well as in pernicious anæmia and congenital porphyria.

Dr. J. C. Houston outlined the view that the body is unable to excrete iron, and that the amount of this element within the body is normally regulated by its absorption, which is strictly limited, according to the needs of the tissues. Apoferritin of the duodenal and intestinal mucosa appears to act as an acceptor. When all the apoferritin has combined with iron to give ferritin, no more iron can be absorbed until some has been given up to the plasma. The factors controlling the rate of release of iron from the mucosal ferritin into the plasma are obscure. The total iron-binding capacity of plasma is normally only about one-third saturated. In hæmochromatosis, serum iron is always above normal, and there is complete or almost complete saturation. The serum iron of hæmochromatosis patients does not increase after oral ferrous sulphate as does that of a normal person. Attempts using radioactive iron to determine the absorption of iron and the amount laid down in the tissue stores have given discordant results, either because of technical difficulties in measuring fæcal radioactivity or because patients have been investigated at different stages of the disease. Very little isotope passed into the blood, presumably because of dilution by a pool of physiologically available iron that is larger than normal. That some of these enormous deposits of iron in hæmochromatosis are available for regeneration of hæmoglobin has been shown by the failure of these patients to become anæmic even after repeated large bleedings. Patients with hæmochromatosis can thus regenerate hæmoglobin at a great rate, and it seems likely that it is the small reserve of available iron which limits the rate of hæmoglobin regeneration after hæmorrhage.

In the subsequent discussion, Dr. W. W. Payne emphasized the importance of the mucosal block in the absorption of iron by reporting a case of fersolate poisoning in which the serum iron concentration reached 20 mgm./100 ml., consequent to the destruction of the intestinal mucosa. In reply to a question from Prof. N. F. Maclagan, Prof. Gray observed that 'fæcal urobilinogen' determinations are of some value in the diagnosis of hæmolytic disease. Prof. H. Munro Fox described how hæmoglobin synthesis in the crustacean *Daphnia* is greatly stimulated by oxygen lack and how, on re-oxygenation, the extra hæmoglobin rapidly disappears, apparently without bile pigment formation. Dr. J. C. White referred to the observation of Haurowitz, that the oxidation of fatty acids is coupled with the breakdown of hæmoglobin to colourless products. Dr. T. With remarked that in the horse the serum bilirubin is much greater than in man, yet in the horse the bile contains very little bilirubin. Dr. M. G. Good was of the opinion that the thyroid influences hæmopoiesis.

---

# EDUCATION IN CHEMISTRY

A DISCUSSION on education in chemistry was held on February 18, under the joint auspices of the London Sections of the British Association of Chemists and the Royal Institute of Chemistry. This attracted an audience of about two hundred people, not only from the London area, but also from various other parts of Britain. Introductory talks were followed by an animated discussion, and altogether twenty-one people spoke in the course of just under three hours. They were representative of the University of London, the Royal Institute of Chemistry, technical colleges, technical schools, the Ministry of Education and industry.

The five introductory speakers dealt with distinct facets of the subject. Prof. C. K. Ingold (University College, London) spoke about the aim of the revised regulations for the Special degree in chemistry of the University of London. A specialist in chemistry, he said, should reach a standard at which he has studied some aspects in sufficient detail, in order to have the right to form an independent judgment. At the same time, the conventional barriers between chemistry and other sciences are breaking down, and it is necessary for chemistry specialists to have a broad background in other sciences. Prof. Ingold thought that sufficient experience has been gained with the Internal degree of the University to be sure that the students trained under the revised regulations are better developed than those trained under the old regulations.

Dr. J. H. Skellon (Acton Technical College) spoke about External degrees in chemistry of the University of London, mainly from the point of view of the technical colleges. He described ways in which these colleges are adjusting their arrangements to fulfil the additional requirements of the new regulations, and thought that there is a danger of the main subject being neglected in the first years of the course. He felt that the new regulations for the External degree should be reconsidered at the end of an experimental period of, say, five years. A point of serious concern is that a student has to decide at the Intermediate science stage whether he will work for the General degree or for a Special degree, and he felt that this is too early a stage for a specialist to be selected. The old arrangement, whereby a man could take the General degree and, one year later, a Special degree, had a distinct advantage.

Prof. Harold Burton (Queen Elizabeth College, London) said that the only professional qualification in chemistry, apart from the Special B.Sc. degree and the associateship of certain technical colleges, is the associateship of the Royal Institute of Chemistry. The Institute had 3,174 registered students at the end of 1952. Approximately three hundred have entered for the examinations in April, and the normal percentages of passes is of the order of 25 per cent. This qualification places more emphasis on practical work than the University of London degree. He pointed out that many candidates are found to be weak in physical chemistry.

Mr. R. W. Blount (Ministry of Education) discussed National Certificates in chemistry, which are qualifications below the professional level. This scheme has been in operation since 1921, and he felt that, apart from providing an indication of the level of training of chemical assistants, it has a distinct value in encouraging organized part-time courses, in raising the standard of accommodation and equipment at many technical colleges, and in bringing students into early contact with their professional institution. He said that the numbers of candidates for the Ordinary National Certificate in chemistry has risen from 358, with 245 passes, in 1946 to 1,285, with 729 passes, in 1952. For Higher National Certificate the increase has been from 112, with 83 passes, to 593 with 364 passes. Further increase is probable, particularly as opportunities for part-time day-study increase.

Dr. Norman Booth (British Oxygen Co., Ltd.) talked about the requirements of industry, in which two out of every three qualified chemists are employed. He stressed that only about one-third of the qualified chemists in industry are engaged on research work, and that more than 8 per cent are engaged on administrative work of various types, including departmental management and membership of boards of companies. This is a growing tendency which should be taken into account when considering the education of chemists. A man with only scientific and technical knowledge will have a limited scope in industry, and the universities should foster other qualities essential both for senior technical and for administrative posts. Dr. Booth also referred to the value to industry of integration of the respective courses for the National Certificate and for the associateship of the Royal Institute of Chemistry.

The discussion which followed covered a wide range of subjects and is not easily summarized. Some purely factual matters raised were answered by the opening speakers. A number of contributors considered that the Special degree in chemistry, although perhaps suitable for those who will become outstanding academic workers, covers too much detail for most chemists' needs. It was believed that a course which pays particular attention to the principles of chemistry and puts more emphasis on practical training would be more valuable generally. Some desirable features are difficult to achieve; for example, a practical examination in physical chemistry cannot be adopted because of lack of examination facilities.

Many speakers referred to the question of flexibility and integration of courses, the object being to enable a person to change from one type of course to another without necessarily having to start at the bottom of the new course. It was generally felt that there could be improvements in the present system. It was suggested that bursaries should be made available to enable promising persons with Higher National Certificate in chemistry to study as full-time students for a degree, either in pure science or a technology.

It was pointed out that the University of London has taken distinct steps to ease the way for admission of students from technical secondary schools, which for some young people might provide the best approach to the chemical profession. Thus, for example, people of mature years are no longer required to have passed a preliminary examination in a foreign language. The ordinary National Certificate in chemistry is regarded as part-fulfilment of the entrance qualification. Further, in the General Certificate of Education, it is not necessary to take all the subjects at once, as was the case with the old matriculation examination.

Mr. L. E. Ball said that the University of London is revising many of the degree courses; but it has not been possible to bring them all into operation at once. He referred particularly to revised General degree regulations which will require the student to take three subjects in his first post-intermediate year and two subjects for a further two years.

Dr. H. B. Nisbet thought it might be possible to arrange a system so that at about General degree standard a person could decide to proceed either to take a technological course or, if he intended to go into research, to take the Special chemistry course. In this way industry would be able to recruit men with training more appropriate to the type of work they are going to do than is the case at present.

It was noted that there is a class of worker in industry, namely, the process worker or plant operator, who would benefit from instruction in the chemical principles underlying the processes he is operating. Although some industrial concerns themselves provide this training, co-operation with the local technical colleges might well be extended.

Other points which arose in the discussion were the continued shortage of teachers of chemistry in schools and its future effect on higher education in chemistry; the necessity for teaching students to express themselves in simple and unambiguous language; the desirability of industry revising its recruiting standards, for example, by taking more people with a General degree and placing less emphasis on a degree with honours in Special chemistry; and how far attempts should be made to educate chemistry students in the humanities.

It is probable that no single point raised during the discussion would have met with unqualified agreement. It was clear, however, that there is no smug satisfaction with the present system of education, and that there are many constructive ideas for improvement. The education of chemists is evidently receiving serious attention by all sections of the chemical community, and perhaps the one thing on which all would agree is that methods of teaching, the content of courses and the regulations must all be adjusted at suitable intervals of time in the light of new knowledge and new demands.

NORMAN BOOTH

# ROYAL COMMISSION ON AWARDS TO INVENTORS

THE Royal Commission on Awards to Inventors, under the chairmanship of Lord Cohen, which was appointed in 1946, has now submitted a third report containing a general survey of the principles which have guided its decisions and some particulars of the more important claims dealt with up to November 8, 1952.

Since hearings started in February 1947, the Commission has sat in public on 278 days and disposed of 325 cases. Many of the claims have presented features of great complexity and have involved hearings extending over several days. About 255 cases were withdrawn after being referred to the Commission. This large number of withdrawals indicates that the procedure adopted by the Commission for enabling the claimant and the government department concerned to set out their case in writing in the first instance has been useful in clarifying and leading to the settlement of many difficult cases without recourse to a hearing.

The Commission, under its terms of reference, can only deal with those cases referred to it by the Treasury or the government department concerned. To assist the department in determining which cases should be referred, the chairman, at the request of the Treasury, set up an Investigating Committee consisting of two or three members of the Commission who carefully examine all claims submitted to it. This Committee has dealt with about 280 claims. Many of the claims comprised several inventions which had to be considered separately.

Sums totalling approximately £616,770 have been awarded since the Commission began its work. By far the largest number of claims has been on an *ex gratia* basis—that is, where the claimant has no legal right to payment but relies upon the bounty of the Crown. Under this heading, for example, the Commission has awarded a total of £94,600 to the inventors of radar installations, including £50,000 to Sir Robert Watson-Watt. A further series of claims for which a total of £23,300 was recommended concerned the inventions (generally known as 'degaussing') used on ships to counteract the German magnetic mine. Other claims concerned the 'Fido' project for dispersing fog from airfields, the 'Leigh' light for aircraft used in anti-submarine warfare and the 'Morrison' table shelter for air-raid protection.

The Commission has also dealt with several legal claims based on the use of patents, in these cases acting in lieu of the High Court. One of these inventions concerned stabilizing gear for reducing the rolling of ships, and the Commission awarded the claimants £27,500.

The Commission has continued the shortened procedure for dealing with claims, for this procedure provides a claimant with a more expeditious and less expensive means of bringing his claim to a hearing.

Although there is still a considerable number of claims outstanding, which the Commission will deal with as and when it is ready for hearing, it can now be claimed that the major part of the task allotted to the Commission has been accomplished.

# COMMONWEALTH FUND

## ANNUAL REPORT FOR 1951–52

THE thirty-fourth annual report of the Commonwealth Fund*, founded on October 17, 1918, by Mr. Stephen V. Harkness (whose residence, Harkness House, New York, was bequeathed to the Fund and is occupied as its headquarters), covers the year ended June 30, 1952. Of the 2·7 million dollars appropriated during the year, 39 per cent was for medical education, 16 per cent for experimental health services, 15 per cent for medical research and 8 per cent for fellowships, including advanced fellowships in medicine and allied fields, particularly for work involving the crossing and re-crossing of interdisciplinary frontiers, and thirty-one British fellowships and nine Salzburg fellowships. The report lists the thirty research projects currently aided by the Fund; and, of the nine which were new or renewed during the year, six relate to integrative processes in man or to crucial factors in the adjustment of man to this environment.

The major interest of the report, however, lies in its account of the experimental work in medical education and in health services supported by the Fund and of the ideas which are guiding these experiments. In medical education, the experiments turn on the assumption, still to be verified, that medical teaching organized around the student's need to learn and the patient's need for care, will prepare students to meet the responsibilities of medicine as a social institution more effectively than medical teaching organized around the preoccupation of teachers with what they as specialists think they ought to teach. To the five-year grant made in 1950 for the reorganization of the curriculum at the Western Reserve School of Medicine, a further grant of 276,428 dollars has been added. This will facilitate a reorganization in which the initial two phases will occupy about two and a half years; first, the student is oriented to medicine and to the patient, presenting the fundamental principles of man's structure, function, growth, behaviour, and relation to his environment; and then, during the second phase, dealing with disease (by general principles and afterwards by organ and site), the teaching will be done by inter-departmental teams on which each man will teach what he is best fitted for; the third and final phase of the reorganization will take a further eighteen months and will deal with the care of sick people.

The second group of experiments embraces grants to the University of Colorado School of Medicine and to the Cornell University Medical College for studies relating to teaching and learning by contact with patients in the clinical years of the medical course, conducted in a new kind of clinic which will put a premium on continuity and comprehensiveness in medical care. If the experiments succeed, they should assist in providing answers to some of the outstanding questions regarding the relation of generalized to specialized medicine, the responsibility for insight into the patient's total problem and the like. The Fund has also made a new grant for the support of the "family general practice" clinic begun at the University of Tennessee College of Medicine in the autumn of 1951, and one of 200,000 dollars for the expenses of a working-party for three years to devise an integrated programme in human biology and ecology at Yale University based on the joint contributions which Yale College and the School of Medicine might make. The Fund has also provided 96,500 dollars towards a study of the state of the resources of the University of Florida which can, and should, be woven into the pattern of medical education.

---

* Commonwealth Fund. Thirty-fourth Annual Report for the Year ending June 30, 1952. Pp. xiii+42 (New York: Commonwealth Fund, 1952.)

In the field of Experimental Health Services the Fund has been most interested in integrating health care, and its main grant has been a further 158,100 dollars in support of the large experiment in integrated health care at the Hunterdon Medical Centre, New Jersey, which a sound and ably led rural community is building, with a further 250,000 dollars to meet the emergency arising from the sharp increase in building costs. In effect, the plan adds a general staff to existing health services of the United States, and also seeks to encourage a keener understanding of people in need of help by stimulating the community to discover and practise mental hygiene. Comprehensive efforts are also being made to obtain a complete picture of the nature and extent of the need for the treatment of chronic illness and disabling conditions and the rehabilitation of their victims.

# THE BOSE INSTITUTE, CALCUTTA

## THIRTY-FIFTH ANNIVERSARY

THE director, Dr. R. C. Mazumdar, before presenting his report on the working of the Bose Institute for the past year, took the opportunity to refer to the fiftieth anniversary of the publication in 1902 of Sir Jagadish Chandra Bose's book "Response in the Living and the Non-living", which had at the time of its publication evoked a great deal of interest. He also announced the receipt of a legacy of £5,000 from the executors of the late Miss Edith Keating, of London. A fellowship is to be created in the Bose Institute, which will be known as the Edith and Richard Keating Research Fellowship.

Satisfactory progress has been made during the past year in the investigations carried out at the Mayapuri Research Station, Darjeeling, on plant virus and microbiological investigations. The different virus strains in seed potatoes, collected from the Seed Potato Farm at Rungbull, have been isolated and identified. Attempts are being made to produce hybrid strains, which will be immune to many of the virus infections, by crossing local commercial strains of potato with different wild South American species. The work planned is a long-range one and cannot be successful without the financial aid and co-operation of the State Department of Agriculture, West Bengal. A scheme for continuation of this work has been submitted to the Government. At Mayapuri other applied investigations of importance to the Darjeeling District, like the introduction of white and red clover from seeds imported from Britain, are being taken up.

The Institute has been selected by the Indian Council for Agricultural Research for carrying out a five-year scheme of investigation on chemical eradication of weeds which infest fields growing rice and other economic crops.

Some aspects of photosynthesis, on which the nutrition of plants and animals are ultimately based, have been studied in the Institute for some time. At present, radioactive carbon imported from Harwell is being employed in the Institute to elucidate as tracer certain problems of assimilation of carbon during photosynthesis.

Successful X-ray irradiation of seeds of economic plants like jute, cotton and oil seeds with the view of evolving new economic types of mutants are being continued. With jute, a tall mutant has been stabilized; chemical examination of the fibre constituents, tensile strength and anatomical studies of the fibres have been started, as well as a method of impregnating with artificial resins bleached jute fibre, for increasing its wet tensile strength.

Nitrogen fixation by soil and nodule bacteria is being studied. Mention was also made in the report of various plant physiological investigations, including cultures of plant tissue in artificial media, and the study of the conditions for producing neoplastic growth in plant cells, similar to the development of cancer cells in animal tissues. The effect of antibiotic substances on plant nuclei is being studied.

The director also reported on the different schemes for providing additional building accommodation for library and workshop, and for the acquisition of a large plot of good agricultural land to the north of Calcutta where the whole agricultural experimental work of the Institute can be centralized. At present considerable difficulty is being met with in maintaining the agricultural experiment stations of the Institute at two different places, one seventeen miles north of Calcutta at Bamangachi, and the other thirty-two miles south of Calcutta at Falta.

Dr. Mazumdar then delivered the fourteenth Acharya Jagadish Chandra Bose Memorial Lecture entitled "Growth of Scientific Spirit in Ancient India".

# RESEARCH IN THE SOCIAL SCIENCES

THE latest issue of that valuable publication, the "Register of Research in the Social Sciences"*, makes it possible to examine the trends of development that have become apparent in social research in recent years. The most important factor underlying these trends is, of course, the 'Clapham' grant given to the universities to make expansions possible in teaching and research in a number of the social sciences, and the effects are evident in the current issue of the "Register". In addition, the Government has taken action in a number of ways to expand social research, notably by direct grants to such bodies as the National Foundation for Educational Research, the British Institute of Management, and the Colonial Social Science Research Council. The provision made in this way has also been supplemented by generous benefactions from private agencies, the most important of which is the Nuffield Foundation.

The immediate impression which a quick survey of the "Register" makes on the mind is that social research is steadily expanding, that advances are, however, in a number of more-or-less disconnected areas rather than along a general line; and that, though an increasing amount of work of fundamental importance is being undertaken, much 'research' is still very superficial, directed too often to mere trivialities, or to objectives which only possess a temporary importance in an administrative context. The truth is, perhaps, that the social sciences are still unable to ask the really important questions with sufficient clarity and simplicity to make it possible to devise effective methods of answering them. The economists have had most success in this endeavour, and this is perhaps why roughly a quarter of the whole of the research work summarized in the "Register" is in the field of economic analysis of one kind or another.

---

* Register of Research in the Social Sciences in Progress and in Plan: No. 9, 1951–52, with a Directory of Research Institutions. Prepared at the National Institute of Economic and Social Research. Edited by Feodora Stone. Pp. 188. (London: Cambridge University Press, 1952.) 15s.

Development appears to be slowest in the exceedingly important area of social behaviour. The need for relating the study of psychology to that of social organization is obviously great, for this is one of the central problems of the social sciences ; yet the whole psychology section devoted to "General Social Problems" only runs to three pages, or about the same length as that of the agricultural economics section. Modern psychiatry only appears in the outlines of researches on rare occasions, as, for example, in those of the Medical Research Council, the Tavistock Institute of Human Relations, and the Institute for the Study and Treatment of Delinquency. The various university research organizations appear for the most part to have been deterred from entering the more adventurous fields of research, and to have been led to attach too high a value to the safe and respectable. Nevertheless, the wastage-rate among Ph.D. students in the social sciences still remains notoriously high. It is probable that the phase of 'settling-down' in social science research will have to go on for some time yet, and that bolder experiments will have to be encouraged, before substantial advances can be made otherwise than on one or two rather narrow fronts.

# RHODOPSIN AND INDICATOR YELLOW

By Dr F. D. COLLINS

Department of Biochemistry, University of Liverpool*

MUCH is now known[1,2] concerning the biochemistry of scotopic vision ; but the chemical nature of the chromophore of rhodopsin (visual purple) is still obscure. When rhodopsin is exposed to light, various changes can be detected. Wald[3] showed that a substance, which he called retinene, could be extracted from retinæ exposed to light, or treated with a polar solvent such as chloroform. Retinene had an absorption maximum at 385 mμ in chloroform, and at 664 mμ in the presence of antimony trichloride dissolved in chloroform. Work in this laboratory[4,5] showed that vitamin A aldehyde was spectroscopically indistinguishable from retinene. This conclusion has been fully confirmed by subsequent investigations[2,6]. This research on retinene demonstrated that the most promising and practicable method of elucidating the chemical nature of rhodopsin and its breakdown products was by comparing their absorption spectra with those of materials prepared in the laboratory. The naturally occurring pigments are present in very small quantities (for example, 3 μgm. of chromophore per ox retina) and all are unstable. However, the fact that rhodopsin is known to give vitamin A aldehyde provides a starting-point for the preparation of compounds for spectroscopic comparison with the naturally occurring pigments.

The position of indicator yellow in the visual cycle has been uncertain ever since it was first described by Lythgoe[7]. He found that a rhodopsin solution after irradiation formed a substance which exhibited variations in spectral absorption with changing *p*H. In alkaline aqueous digitonin the absorption maximum was at 365 mμ while in acid it was changed to 440 mμ. Work in this laboratory[8-10] showed that vitamin A aldehyde would combine, in alkaline solutions only, with aliphatic amines (in excess) to form a substance with an absorption maximum at 365 mμ (solvent, aqueous ethanol). On the addition of one drop of concentrated hydrochloric acid, the maximum shifted to 440 mμ. It was thus clear that indicator yellow must be a compound of retinene and a free amino-group, perhaps attached to a protein.

Two alternative conclusions are possible. (1) Retinene (in this case the first stable product of the bleaching of rhodopsin) would combine with any free amino-groups (for example, amino-acids or proteins) which might be present. "In this case indicator yellow would be a fortuitous artefact having no direct relevance to visual chemistry"[8]. Although retinene will only combine with amino-groups at an alkaline *p*H, indicator yellow is none the less formed in irradiated rhodopsin solutions buffered at an acid *p*H[10]. This objection can be met by assuming that retinene, when first formed as a result of the irradiation of rhodopsin, is in an 'activated' form and that this 'activated' form combines rapidly with any free amino-groups. (2) The alternative conclusion is that the carbon-to-nitrogen bond present in indicator yellow is also present in rhodopsin.

On the basis of the first proposition, it might be expected that formation of indicator yellow would be totally prevented by 'blocking' the free amino-groups. A well-established means of doing this is by the use of formaldehyde[11-13], as exemplified by the formol titration of amino-acids and proteins. A number of experiments have been carried out to test the validity of the above line of thought.

From the work of Levy[11,12] and his co-workers the reaction between an amino-acid and formaldehyde can be formulated as follows :

$$R\text{—}\overset{+}{\mathrm{N}}\mathrm{H}_3 \rightleftharpoons R\text{—}\mathrm{NH}_2 + \mathrm{H}^+$$
$$R\text{—}\mathrm{NH}_2 + \mathrm{HCHO} \rightleftharpoons R\text{—}\mathrm{NH}\text{—}\mathrm{CH}_2\mathrm{OH}$$
$$R\text{—}\mathrm{NH}\text{—}\mathrm{CH}_2\mathrm{OH} + \mathrm{HCHO} \rightleftharpoons R\text{—}\mathrm{N}(\mathrm{CH}_2\mathrm{OH})_2$$

From the data[11,12] it is possible to calculate the proportion of these forms which will be present in a given set of conditions (see table). The amount of free amino-nitrogen in a rhodopsin solution is small, and an upper limit was established as follows. Two solutions (each 1 ml.) of rhodopsin ($13 \times 10^{-6}$ *M* in respect to retinene) gave readings in a manometric Van Slyke apparatus which did not differ from the blank reading by more than 1·7 mm. of mercury, a difference which corresponds to 3 μgm. amino-nitrogen per ml. : to be quite certain, an upper limit of 5 μgm. amino-nitrogen per ml. was assumed, which is equivalent to $360 \times 10^{-6}$ *M*. Assuming that the amino-groups are all present in the form of tyrosine (the amino-acid with the least affinity for formaldehyde) and that the 'activated' retinene reacts equally well with the two forms of the free amino-group

---

* At present at the Department of Biochemistry, Australian National University, Canberra.

Extent of the reaction between amino-acids and formaldehyde, as calculated from the data of Levy and Silberman (ref. 11), at $p$H 9. Total concentration of amino-acid put equal to 1·00

| Amino-acid | Tyrosine | | Leucine | | Lysine | |
|---|---|---|---|---|---|---|
| Formaldehyde conc. | 2·67 *M* | 10 *M* | 2·67 *M* | 10 *M* | 2·67 *M* | 10 *M* |
| $R$—$\overset{+}{\mathrm{N}}\mathrm{H}_3$ | 0·018 | 0·0019 | 0·0107 | 0·00086 | 0·013 | 0·00109 |
| $R$—$\mathrm{NH}_2$ | 0·015 | 0·0017 | 0·0084 | 0·00027 | 0·00035 | 0·000030 |
| $R$—$\mathrm{NH(CH_2OH)}$ | 0·415 | 0·17 | 0·145 | 0·044 | 0·22 | 0·072 |
| $R$—$\mathrm{N(CH_2OH)_2}$ | 0·552 | 0·83 | 0·840 | 0·954 | 0·76 | 0·926 |

($R$—$\overset{+}{\mathrm{N}}\mathrm{H}_3$ and $R$—$\mathrm{NH}_2$), which is unlikely, then the concentration of amino-nitrogen available for reacting with the retinene will be $12 \times 10^{-6}$ *M* for 2·67 *M* formaldehyde and $1 \cdot 3 \times 10^{-6}$ *M* for 10 *M* formaldehyde, both at $p$H 9. These two figures are 92 per cent and 10 per cent of the available retinene and are the maximum amounts of free amino-nitrogen that could be present. From these figures it is apparent that, if a $p$H of 9 and a formaldehyde concentration of 10 *M* are used, the amount of free amino-nitrogen will be less than one-tenth of the retinene present (molar concentrations). These conditions would allow the two hypotheses to be distinguished: if the first alternative is correct, not more than 10 per cent of the retinene will be present as indicator yellow. If the second alternative is the correct one, then the amount of indicator yellow will approach 100 per cent.

On the second hypothesis, some retinene is to be expected, as the following evidence demonstrates. Retinene combines with methylamine to form a Schiff's base[14] ($R$.CH=NCH$_3$) which has nearly the same absorption maximum as alkaline indicator yellow and which on acidification gives a compound with an absorption band at 440 mμ. If the Schiff's base is dissolved in water (0·15 *M* borate buffer $p$H 9·3) with the aid of 'Tween 80', the absorption maximum changes from 363 mμ (characteristic of alkaline indicator yellow) to 383 mμ (characteristic of retinene) (see Fig. 1). This change is unimolecular with a half period of 25 min. at room temperature (about 18° C.). Therefore, if indicator yellow is formed directly from rhodopsin on irradiation, some retinene will be formed by hydrolysis even before the absorption spectrum can be measured. With the above considerations in mind, the following experiment was carried out (other similar experiments have given the same results). A rhodopsin solution was prepared from cattle rod outer segments as described by Collins, Love and Morton[15]. The rhodopsin was extracted with 2 per cent aqueous digitonin, and 1 ml. of this solution was mixed with 3 ml. of 40 per cent formaldehyde which had been adjusted to a $p$H of 9. The extinction at 500 mμ was recorded and the solution bleached with a photoflood lamp. The absorption curve was then measured at intervals up to 60 min. (see Fig. 2). Finally the extinction at 500 mμ was measured, as was the $p$H. The difference before and after irradiation in the extinction at 500 mμ (0·760 − 0·032 = 0·728) was a measure of the amount of rhodopsin present. Using the figure for the molecular extinction coefficient (in terms of a $C_{20}$ molecule) of 48,000[15], the total concentration of retinene in the final solution would be $15 \cdot 2 \times 10^{-6}$ *M*.

The curves shown in Fig. 2 have a well-defined isosbestic point, from which it follows that one material is being transformed into one other substance. The final absorption curve corresponds closely to that of retinene, while the initial curve differs comparatively little from that of alkaline indicator yellow. As the irrelevant absorption does not alter during the change of indicator yellow to retinene (because of the isosbestic point), the difference in the extinction between that at any particular time and the final reading is a direct measure of the indicator yellow present at that time.

If $x$ be concentration of retinene at time $t$ after irradiation of the rhodopsin solution, and $y$ the concentration of alkaline indicator yellow when the concentration of retinene is $x$, then the final concentration of retinene will be $x + y$. The molecular extinction coefficient of retinene at 360 mμ (aqueous) is 28,200, while that of alkaline indicator yellow is 50,000[13,14]. Hence, using the points on Fig. 2 at 360 mμ, the following equation will hold:

initially $28{,}200\ x + 50{,}000\ y + i = 0 \cdot 676$, where $i$ = irrelevant absorption;

finally $28{,}200\ (x + y) + i = 0 \cdot 543$;

subtracting, $y\ (50{,}000 - 28{,}200) = 0 \cdot 133$;

and hence $y = 6 \cdot 1 \times 10^{-6}$ *M* or 40 per cent of the total retinene.

In another experiment at the same $p$H and strength of formaldehyde, the indicator yellow represented 49 per cent of the total retinene. In both cases the lower limit of the indicator yellow concentration was at least four times the upper limit of the free amino-nitrogen. That the first is a lower limit is evident from the fact that the reading at 360 mμ, after irradiation of the rhodopsin solution, was falling rapidly and that the true initial concentration was certainly higher. The time between the beginning of irradiation and the measurement of the extinction

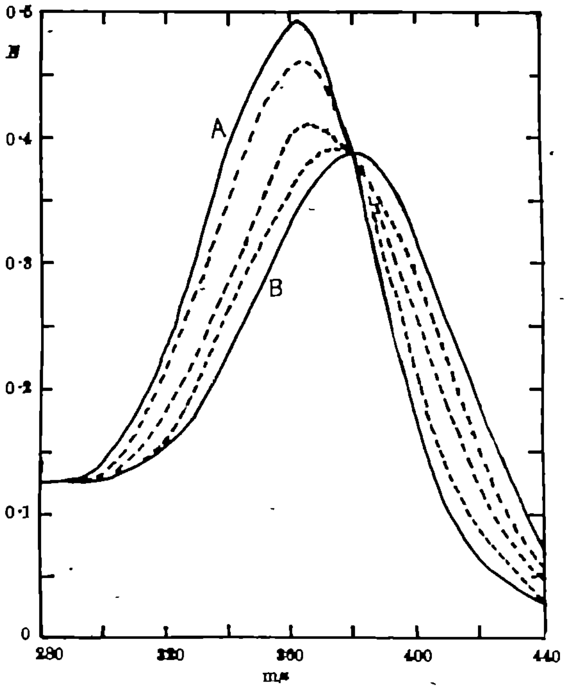

Fig. 1. Retinene methylimine dissolved in aqueous 0·15 *M* borate buffer ($p$H 9·3) with the aid of 'Tween 80'. The first absorption curve *A* was measured as soon as possible after solution had been effected. Curve *B* was measured after 170 min. The absorption curves were measured at frequent intervals between these two extremes, three of which are shown. The rate of change was unimolecular with a half-period of 25 min.

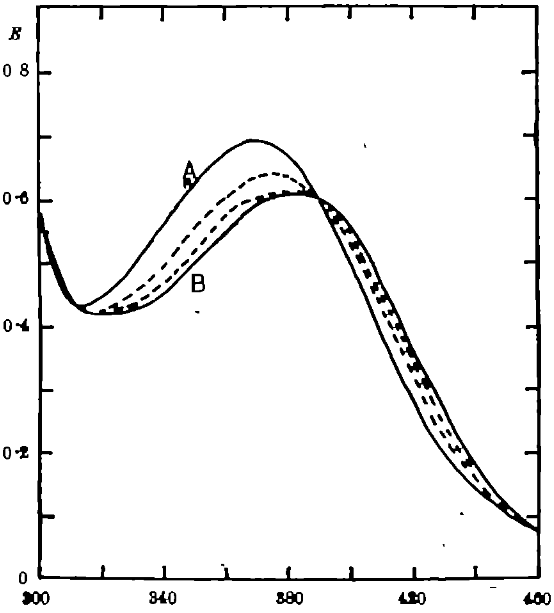

Fig. 2. A rhodopsin solution (in 0·5 per cent (w/v) aqueous digitonin, 10 *M* formaldehyde and enough alkali to bring the *p*H to 9·0) was irradiated and the absorption spectrum measured (*A*). The absorption spectra were measured at frequent intervals (two being shown) and finally after 60 min. (*B*). The rate of change was unimolecular with a half-period of 9·0 min.

at 360 mμ was five to ten minutes, and in this time the concentration of indicator yellow would have fallen rapidly. In the two experiments just described, the difference between the extinction at 360 mμ and the final reading at this wave-length fell off at a unimolecular rate. The values of the rate-constant were − 0·031 and − 0·037, corresponding to a half-life of 9·8 and 8·3 min., respectively, the mean half-life being about 9 min. It is thus evident that all the retinene could have been in the form of indicator yellow immediately after bleaching.

Two differences are apparent between the alkaline form of indicator yellow and the compound between retinene and methylamine. First, the isosbestic points (the wave-length at which indicator yellow or its analogue and retinene have the same value of the molecular extinction coefficients) are different—380 mμ for retinene methylimine, and 389 mμ for indicator yellow. However, retinene in combination with proteins and compounds such as β-alanine and glycine has an isosbestic point with retinene at 386–390 mμ. The second difference is that indicator yellow is hydrolysed by water more rapidly (half-life, 9 min.) than is retinene methylimine (half-life, 25 min.). This difference in the rate of hydrolysis and in the isosbestic point indicates that, although retinene methylimine is an analogue of indicator yellow, it is not an exact one. This is most probably because a methyl group is unlikely to simulate exactly an amino-acid radical or other large group.

These experiments demonstrate that indicator yellow is not a fortuitous artefact, and it thus follows that an understanding of the chemistry of indicator yellow and its analogues is essential to the elucidation of the chemical nature of rhodopsin. Retinene combines with methylamine to yield a crystalline material with an absorption maximum at 365 mμ in ethanol (melting point 73° C.; per cent nitrogen 4·82; molecular weight (rast-camphene) 290). This corresponds to a simple Schiff's base (retinene methylimine). On acidification, a substance with an absorption maximum at 440 mμ in ethanol is obtained. The purest preparation of this analogue of acid indicator yellow had $E$(1 per cent, 1 cm.) (465 mμ in chloroform) = 1,200, melting point 140° C. and 3·9 per cent nitrogen; this material was unstable and to date has not been obtained as a pure crystalline material. The hydrochloride of retinene methylimine would not differ in its absorption maximum greatly from the free imine, and an absorption maximum at 440 mμ would imply a doubled molecule. Collins and Morton[10] put forward provisional formulæ for acid and alkaline indicator yellow, which they claimed were the simplest explanations of the facts. Their conclusions were in principle correct; alkaline indicator yellow is now known to be a Schiff's base, but the acid form may well be a more complicated molecule than that proposed by Collins and Morton. Until the structure of acid indicator yellow is known, it is not possible to say more except that a carbon-to-nitrogen bond must be present in rhodopsin.

Workers in the field of visual chemistry have been divided in their assessment of the role of indicator yellow. Some[7,16,17] have always accepted indicator yellow, although on mainly circumstantial evidence, whereas others (notably Wald and his co-workers[6]) have minimized its importance. The present work demonstrates that indicator yellow is a key substance in visual chemistry and represents a close approach to rhodopsin. How close is demonstrated by the following experiment.

Retinene methylimine was dissolved in chloroform and treated with a solution of antimony trichloride in chloroform. The resulting solution had an absorption maximum at 505 mμ, changing to 497 mμ within ten minutes. Like rhodopsin (which has its absorption maximum varying from 503 to 496 mμ, according to the species from which it is obtained), the band is broad (half-width 110 mμ, rhodopsin 100 mμ). Although this product differs from rhodopsin in several respects (that is, it is relatively thermostable, is photostable and is produced under unphysiological conditions), this result is none the less a clear indication of the potentiality of retinene imines.

Thanks are due to Prof. R. A. Morton, without whose help and encouragement this work would not have been possible. Thanks are also due to Dr. H. K. King for the amino-nitrogen estimations, and to Dr. A. L. J. Buckle, of the Organic Chemistry Department, University of Liverpool, for the determinations of nitrogen (micro-Dumas) and of molecular weight.

# CYTOPLASMIC LOCALIZATION OF NUCLEIC ACIDS IN PLANT CELLS

By J. CHAYEN and K. P. NORRIS

Wheatstone Physics Laboratory, King's College, University of London, W.C.2

It is generally conceded that the nucleic acids are of major importance in the cell. Thus, protein synthesis is almost invariably associated with a high concentration of ribose, or pentose, nucleic acid[1]; and the consistent occurrence of deoxyribose nucleic acid on the chromosomes, even in interphase nuclei, and on the bands of the salivary gland chromosomes of *Drosophila* has led Muller[2], among others, to consider that the gene may be composed of deoxyribonucleoprotein. This conclusion has gained support from the work of Vendrely and of Mirsky, who have used biochemical procedures, and of many others who, by using staining and photometric methods, have shown that diploid nuclei apparently contain twice the amount of deoxyribose nucleic acid present in sperm and approximately half that found in nuclei believed to be tetraploid.

The method most commonly utilized for demonstrating the localization of deoxyribose nucleic acid in cells is the Feulgen reaction. There has been considerable controversy concerning how far this test is specific[3] and whether deoxyribose nucleic acid, with or without the recolorized leuco-basic fuchsin, could diffuse about the cell. Moreover, cytologists have felt that the hydrolysis involved in this reaction, namely, heating the tissue in normal hydrochloric acid for 6 min. at 60° C., was an undesirable part of the procedure.

More recently, Kurnick[4] has developed a method by which polymerized nucleic acid can be stained by a stoichiometric reaction with purified methyl green. It is generally assumed that whereas deoxyribose nucleic acid occurs as a very highly polymerized molecule, ribose nucleic acid is present in cells as a relatively small molecule and hence does not give this stoichiometric reaction with methyl green. While this assumption may be true of aged and differentiated cells, it is not entirely correct for plant meristematic cells, in which some of the ribose nucleic acid may also be polymerized sufficiently to give this reaction; for this reason we have used Kurnick's methyl green method in conjunction with treatment with deoxyribonuclease, acting in the presence of a protease inhibitor[5], to locate deoxyribose nucleic acid. It should be noted that many popular fixatives and treatments apparently depolymerize the ribose nucleic acid, thus removing from it this property of binding methyl green.

A third method of studying the cellular distribution of nucleic acids is by ultra-violet absorption microscopy. Maximal absorption at about 2600 A., the absorption maximum of both the nucleic acids, does not allow differentiation between ribose nucleic acid and deoxyribose nucleic acid, and, if not supported by other evidence, must be interpreted with considerable caution[6].

In our study of the distribution of nucleic acids in cells of plant root meristems, and in particular in the roots of *Vicia faba*, we have been unable to use the Feulgen reaction because the cytoplasmic particles of these cells are readily destroyed by the acid hydrolysis, and clearly it would have been absurd to discuss the localization of substances in cells in which important structures have been destroyed. It has also been found that the cytoplasmic granules are easily disintegrated by other treatments which might have been considered much less drastic than hydrolysis with hot acid. Thus, in cells fixed in neutral formalin, these organelles are lost when the *p*H is lowered to about *p*H 5, so that after such fixation Kurnick's methyl green reaction had to be performed in acetate buffer at *p*H 6 instead of the customary *p*H 4·2.

We have found a constant correlation in the root meristem cells of the broad bean, treated with various techniques, between preservation of cytoplasmic granules and paucity of nuclear absorption at 2650 A., and of nuclear basophilia. Techniques which have been found suitable for demonstrating this include living preparations[7,8], the polyvinyl alcohol–pectinase method[9], neutral 'Formalin–aquax'[10], the Newcomer–Zirkle procedure[10,11], and freeze-drying. In the first two procedures the cells are studied whole in squash or smear types of preparation, whereas in the last three they are examined in sections. On the other hand, when the cytoplasmic granules are destroyed, the nucleus becomes strongly absorbing at 2650 A. and intensely basophilic. This effect may be produced by destroying the granules (for example, by treatment with hot acid) in preparations made by any of the above methods, by fixation in acetic alcohol and either embedding in paraffin or separating the cells in hot hydrochloric acid, or by fixing the roots in hot 45 per cent acetic acid.

When cells containing well-preserved cytoplasmic granules are stained overnight with purified methyl green at *p*H 6 and then washed in buffer at the same *p*H for several hours, only the granules and nucleoli retain the stain appreciably, suggesting that these sites alone contain polymerized nucleic acid. Thus the resting nucleus, apart from the nucleolus, does not retain the stain. The colour of the stained structures is blue-green, quite unlike the vivid green usually produced by the reaction of this dye with cellulosic or lignified structures. If, however, the granules are destroyed by gentle treatment which should have less effect on the polymerization of nucleic acid than hydrolysis in hot acid (for example, by changing the *p*H to 4), it is the nucleus and nucleolus which retain the stain, indicating that the polymerized nucleic acid has become attached to these structures. If the intact cytoplasmic granules are treated with deoxyribonuclease in the presence of a protease inhibitor, they lose all or most of their ability to retain methyl green. Furthermore, nucleolar basophilia and absorption at 2650 A. are lost after the cells have been treated with normal hydrochloric acid at 60° C. for 6 min., which removes ribose nucleic acid from root meristem cells.

It has been shown[9] that if living cells are treated overlong with commercial pectinase, the granules are reduced in number while the nucleus becomes more refractile and increases in density when viewed with stopped-down green illumination, indicating that material has diffused into the nucleus. We have checked that this change of refractivity is not due to light being lost from the system by scatter, etc. (for example, apparent absorption at 3100 A. remains small). A similar effect has often been observed by us when living cells, separated by the pectinase technique, are mounted in Tyrode solution which has been diluted four times with distilled water. Samples of nuclei photographed at 2650 A. after such diffusion has taken place, when compared with samples photographed before the change, suggest a three- to five-fold increase in absorption at this wave-length. A similar result has also been seen in cells prepared in other ways.

We have now followed this change while it occurred in one cell. The bean root had been treated by the pectinase method for separating living cells[8], macerated in distilled water, and photographed immediately at 2650 A. Diluted Tyrode solution was added to the side of the coverslip and almost immediately the interphase nucleus, viewed in green light, began to darken. Serial photographs taken at 2650 A. at three intervals after the addition of dilute Tyrode solution showed a progressive increase of nuclear absorption at this wave-length. This has been confirmed by microphotometry. Of particular interest, however, is the fact that while the nucleolar absorption at 2650 A. in the first photograph is considerably higher than that of the rest of the nucleus and of the cytoplasm, it becomes progressively masked by the rising absorption of the rest of the nucleus although the nucleolus neither lost absorption nor altered in size.

Thus a transfer of absorbing material has been recorded in one cell in which the cytoplasmic granules were disintegrating, the interphase nucleus having been seen to change from a poorly absorbing body to one which absorbed very strongly at 2650 A. To this observation may be added the results with methyl green which suggest that at least much of the deoxyribose nucleic acid is cytoplasmic when the cytoplasmic organization is intact, but nuclear when these granules are disturbed. It has been shown previously[12] that the destruction of these granules does not necessarily cause the absorbing material to shift from the cytoplasm to the nucleus. Thus suitable treatment with acetic alcohol leaves the interphase nucleus weakly absorbing, although when such cells are heated at 60° C. in normal hydrochloric acid for 6 min. the absorption of the nucleus increases several-fold. It is for this reason that the cytoplasmic localization of deoxyribose nucleic acid cannot be demonstrated by the Feulgen reaction which not only destroys the granules but also, as in this case, causes a shift of the freed deoxyribose nucleic acid (or deoxyribose nucleic acid-protein) into the nucleus. It is important to note, however, that this change of cytoplasmic to nuclear localization is observed only in these plant root meristem cells; it is not found in other proliferating cells such as those of the staminal hairs of *Tradescantia*, in which there are no large cytoplasmic granules of the type found in the root meristem cells. Since these granules comprise the mitochondria and similar organelles, it seems reasonable to assume that the cells which contain such bodies are capable of considerable synthetic activity, whereas those which do not possess these structures are less active metabolically and also show a different localization of all or most of the deoxyribose nucleic acid.

At first sight these findings seem to contradict many well-established ideas concerning the chemical nature of the gene and the nucleic acid cycle in mitosis, but this is not necessarily so. For example, no evidence has been presented to show that there is no deoxyribose nucleic acid in the interphase nucleus; absolute measurement is made difficult by the over- and under-lying cytoplasm and by the apparent accumulation of ultra-violet-absorbing cytoplasmic bodies close to the nuclear-cytoplasm boundary. Furthermore, Darlington[13] has stated clearly that although maximum attachment of the deoxyribose nucleic acid to the chromosomes corresponds to maximal spiralization, that is, at metaphase, "At the other extreme, within the resting nucleus, they [the chromosomes] are uncoiled and relatively free from nucleic acid". The present investigation provides no information about the attachment of the nucleic acid to the mitotic chromosomes. Furthermore, since the evidence offered in the present communication depends on cytochemical results, the possibility cannot be excluded of the presence on the granules of some basophilic, ultra-violet-absorbing substance which is removed by deoxyribonuclease but which is yet distinct from deoxyribose nucleic acid. This could be examined by biochemical procedures only if they could be shown not to disturb the delicate cytoplasmic structures, so causing the same artefacts as are discussed above.

The results described above, however, emphasize certain points. First, in actively synthesizing cells it is possible that some, if not most, of the deoxyribose nucleic acid is cytoplasmic, even if it is only partly synthesized or stored there[14]; at least it should not be treated as axiomatic that all deoxyribose nucleic acid must be in the nucleus. Secondly, it follows from this that the Feulgen reaction, in plants if not in other organisms, is of little cytochemical value unless the final preparation compares favourably with living cells; this is likely to be true only if there are no structures present in the cell which both contain deoxyribose nucleic acid and are destroyed at a pH below about pH 5. Thirdly, it may be as well to accept with caution the assumption that the gene is necessarily composed of deoxyribonucleoprotein. At least it may be argued that other evidence of the gene-nature of this complex is required before the gene is actually defined in terms of deoxyribonucleoprotein. Similar conclusions, based largely on other observations, have been discussed previously[12]. The present communication is a summary of experiments conducted during the past four years and a full account of the results will be published elsewhere.

This work owes much to the specialized advice on the various facets of the problem and the encouragement which we have received. In particular, we wish to acknowledge our gratitude to Prof. J. T. Randall, who has made this research possible and whose encouragement has greatly assisted us, and to Dr. H. B. Fell, for her frequent kind and valuable advice. We are grateful to Prof. J. F. Danielli, Dr. C. D. Darlington and Prof. J. Brachet for helpful discussions and for advising us with regard to the manuscript, and to Sir Rudolph Peters for his encouragement in the work. We wish to express our gratitude to Dr. M. H. F. Wilkins for his advice on biophysical problems, and to various of our colleagues at King's College for their help and friendly discussions. We are indebted to the British Empire Cancer Campaign (J. C.) and the Rockefeller Foundation (K. P. N.) for grants which have enabled this work to be done.

## A New Procedure for Correlating the Structure of Glycosides

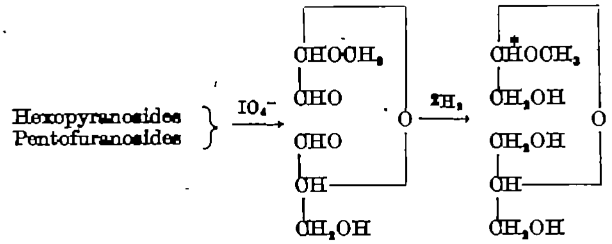
WHEN a sugar glycoside is oxidized with periodate, the ring is severed and a dialdehyde is formed[1]. In the case of pyranosides, cleavage is accompanied by the elimination of the $-CH(OH)-$ group at $C_3$ as formic acid, whereas in the cleavage of pentofuranosides no formic acid is formed. The elucidation of this reaction by recognition of the dialdehydic character of the periodate oxidation product[1] and an extensive study of the corresponding dibasic acids and their salts have enabled the ring structure of glycosides to be determined and have provided a simple method for correlating the structure of the various glycosides[2].

We wish to report another procedure for correlating the structure of glycosides, which consists of the reduction, either catalytically (in alcohol at 100° C. with 1,500 p.s.i. hydrogen and Raney nickel) or with sodium borohydride (in aqueous solution at 25° C.), of the dialdehydes formed by periodate oxidation and an examination of the corresponding alcohols so formed. The dialdehydes (I) from the hexopyranosides and pentofuranosides give the alcohol (II), while the dialdehydes (III) from the pentopyranosides furnish the alcohol (IV). Similarly, the dialdehydes (V) from the 6-deoxy-hexopyranosides yield the alcohol (VI).

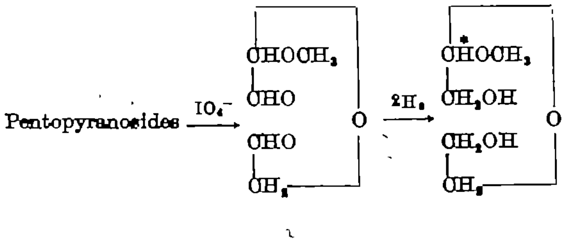
When the dialdehyde (I) is hydrogenated under pressure in the presence of a palladium-charcoal catalyst at room temperature, only the aldehydic group at $C_4$ of the original glycoside is reduced.

There is only one centre of asymmetry in the alcohols II and IV. Consequently, all the α-methyl-D-hexopyranosides and all the β-methyl-L-hexopyranosides should give the same optically active alcohol (*A*). Similarly, all the β-methyl-D-hexopyranosides and all the α-methyl-L-hexopyranosides should furnish the same optically active alcohol (*B*) which is the enantiomorph of *A*. The same relationship should exist among the alcohols (IV) produced from the α- and the β-methyl-D- and L-pentopyranosides. Experiments carried out on the glycosides of D-glucose, D-mannose, D-galactose, D-xylose and L-arabinose have shown that these relationships do actually hold true.

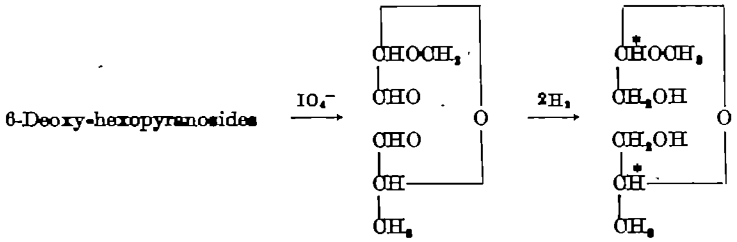
The alcohols represented by the general formulæ II, IV and VI, which can be produced in almost quantitative yield, are colourless fairly mobile liquids and they can be distilled *in vacuo* without decomposition. The enantiomorphic alcohols (II) obtainable from the hexopyranosides and pentofuranosides give the corresponding enantiomorphic tribenzoates, melting point 66°, $[\alpha]_D^{20}$ + 21° and − 21° (ethanol), and the *tris-p*-nitrobenzoates, melting point 110°, $[\alpha]_D^{20}$ + 24° and − 24° (chloroform). The enantiomorphic alcohols (IV) from the dialdehydes (III) furnished by the pentopyranosides yield the enantiomorphic *bis p*-nitrobenzoates, melting point 113°, $[\alpha]_D^{20}$ + 10° and − 10° (chloroform). The diasteroisomeric alcohols corresponding to (VI) from the aldehydes (V) provided by the 6-deoxy-hexopyranosides have been characterized as *bis p*-nitrobenzoates. The structures of the alcohols represented



(I) (II)

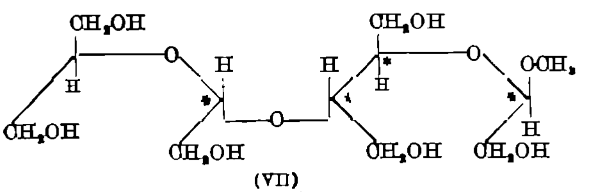


(III) (IV)

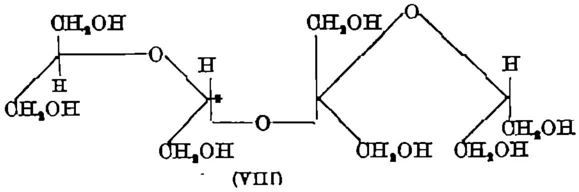


(V) (VI)

* Denotes an asymmetric carbon atom.



(VII)



(VIII)

by the formulæ II and IV have been established by acid hydrolysis and identification of the fragments, namely, glycerol (from II), ethylene glycol (from IV) and glycollic aldehyde (from II and IV). Confirmation of these results has been obtained from experiments carried out with the benzoyl and *p*-nitrobenzoyl derivatives of the alcohols.

Proof of the structure of the alcohols represented by VI may be illustrated by reference to that obtained from α-methyl-L-rhamnopyranoside. This particular alcohol affords upon hydrolysis glycollic aldehyde (2,4-dinitrophenylhydrazone, melting point 86°) and an optically active 1,2-propanediol (*bis p*-nitrobenzoate, melting point 109°, $[\alpha]_D^{23} + 48 \cdot 5°$ (acetone) ), which proved to be identical with that obtained from L (dextro)-lactic acid and its methyl ester by reduction with lithium aluminium hydride.

We have also found that reduction of aldehydes, formed by periodate oxidation of glycosides, is also applicable to oligosaccharides. Thus β-methyl maltoside has given VII whereas sucrose has afforded VIII.

Furthermore, the fact that the latter, which contains only one asymmetric carbon atom ($C_1$ of the original D-glucose moiety), has a negative rotation shows that in sucrose the anomeric linkage at the glucose residue is of the α-type, inasmuch as all alcohols of the type represented by II (an analogue of VIII) derived from α-alkyl-D-glucopyranosides have a negative rotation, whereas all those derived from β-alkyl-D-glucopyranosides have a positive rotation.

Further details of this work will be published later.

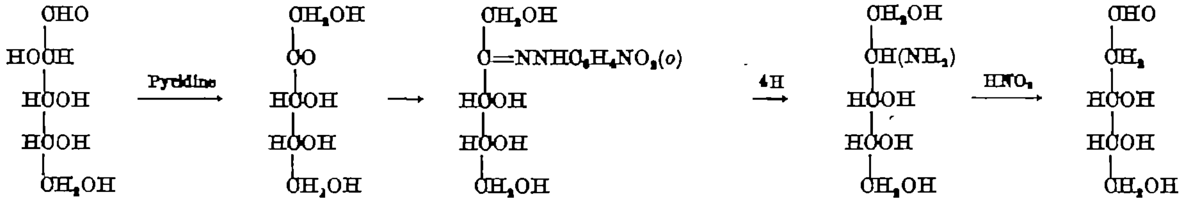
## A New Synthesis of 2-Deoxy-D-ribose

It has long been a matter of interest to synthesize 2-deoxy-D-ribose, a component sugar of deoxyribonucleic acid, and several methods have been reported[1]. We wish to communicate some results which we obtained recently.

D-Arabinose was converted into ribulose by heating it in pyridine[2]. Ribulose isolated as its *o*-nitrophenyl hydrazone was reduced as such with Raney's nickel catalyst to the 2-deoxy-2-amino-pentitols, the crystallization of which failed. The amino-alcohols were converted into deoxy-pentose by treatment with nitrous acid. The course of the reaction may be interpreted as a sort of 'semipinacolinic deamination'[3]. 2-Deoxy-D-ribose was isolated as its benzylphenyl hydrazone melting at 125·5–126·5° C., $[\alpha]_D^{11}$ being − 15·25°. The overall yield was about 3 per cent. The whole course of the reaction is represented as follows :



We are indebted to Prof. K. Makino and Mr. K. Ohta, of the College of Medicine, Kumamoto University, for an authentic specimen of deoxyribose, and we are grateful to Prof. S. Akabori, of the College of Science, Osaka University, for his suggestions and encouragement.

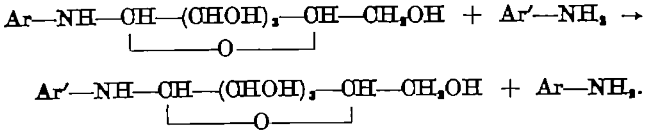
## Transglucosylation of Aromatic N-Glucosides

Although the transglucosylation of O-glucosides is not very practicable and has been described hitherto only in isolated cases[1], the same mechanism appears in the case of N-glucosides of primary aromatic amines and seems to be fairly easy and to proceed according to the reaction :



$$\mathrm{Ar{-}NH{-}\underbrace{CH{-}(CHOH)_2{-}CH}_{O}{-}CH_2OH + Ar'{-}NH_2 \rightarrow Ar'{-}NH{-}\underbrace{CH{-}(CHOH)_2{-}CH}_{O}{-}CH_2OH + Ar{-}NH_2.}$$

The first example of this reaction was given in 1936 by R. Kuhn and A. Dansi[2], who in this way prepared nitroxylidine-glucoside from *p*-toluidine-glucoside, but the yield was very low. In 1948, J. Inoue and K. Onodera described two further reactions, namely, the preparation of aniline-glucoside and *m*- or *p*-nitraniline-glucoside from *p*-toluidine-glucoside ; however, the description of the latter seems to me doubtful ("white tabular crystals (?), m.p. 120–122°, of aniline N-D-glucoside"[3]).

Since this process appears to be of significance both from the chemical and biochemical points of view, we have made detailed investigations of the conditions and mechanism of the reaction. Our conclusions can be summarized as follows :

(1) The reaction is dependent upon *p*H.

(2) It is in certain circumstances reversible (see examples 4–5, 6–7 and 8–9 in the accompanying table).

(3) The reaction will proceed to completion in solvents such as methyl alcohol and ethyl alcohol in a few minutes at low temperature with very satisfactory yields ; Inoue and Onodera heated the reaction mixtures for eight hours. We find that application of heat serves only to speed up the solution of the starting reactants.

(4) The reactions in absolute alcohols leave little doubt that the process is really transglucosylation rather than hydrolysis followed by redistributive reglucosylation. This conclusion is confirmed by the

fact that the transformation of *p*-aminosalicylic acid-N-glucoside into sulphanilamide-N⁴-glucoside will proceed at a considerably higher velocity than the formation of the corresponding glucoside from a mixture of *p*-amino salicylic acid, sulphanilamide and glucose under the same conditions. It should be noted, however, that water at a concentration of less than 5 per cent will not, in most cases, influence formation and yield of the product and the velocity of transglucosylation. However, in special cases the presence of water is advantageous on account of the crystallization and separation of the products from the mixture. The solubilities of the components evidently play a very important part in these reactions.

(5) In the examples described in the table, the amines were used in about 1 or 2 mol. excess. In the reversible reactions, we never used more than 2 moles of amines.

(6) We find that not only the free glucosides but also the tetra-acetylglucosyl derivatives can be subjected to transglucosylation. Sulphanilamide-N⁴-tetra-acetylglucoside could be prepared from aniline-tetra-acetyl-glucoside both from a mixture of the α,β-isomers and from the pure α- or β-isomer. An isomeric mixture was obtained which was almost identical with that obtained from sulphanilamide and tetra-acetylglucose or acetobromglucose respectively[4].

The transglucosylations indicated in the table have been accomplished.

Detailed description of the experiments will appear elsewhere. We thank the Hungarian Academy of Science for assistance in this investigation.

## Demonstration of Transaminase Systems in the Alga *Chlorella*

As part of a programme of study of the nitrogenous metabolism of the alga *Chlorella* being undertaken in this department, it was considered desirable to obtain evidence for the presence or absence of transaminase systems within the organism, and to evaluate the relative activities of any such systems found to be present. The organism used was a strain of *Chlorella vulgaris* identical with that used in the experiments described by Syrett and Fowden[1].

Preliminary experiments had shown that large amounts of material are often required to demonstrate metabolic processes in *Chlorella*, even though micromethods may be used for their investigation. For this reason the alga was grown in a 10-lit. 'Pyrex' aspirator, containing 8 lit. of medium similar to that used by Syrett and Fowden and illuminated by four vertical, equally spaced 40-watt fluorescent tubes. The temperature was that of the laboratory, varying in the range 15–22° during the course of the experiment. The medium was aerated with air plus 0·5 per cent carbon dioxide, the total gas flow being approximately 100 lit./hr. This vigorously stirred the large volume of liquid, ensuring that all the cells were intermittently exposed to the light at the edges of the culture, even when penetration of light into the bulk of the culture was reduced to a very low level at the later stages of growth. The medium was inoculated with 20 ml. of an actively growing *Chlorella* suspension growing in the same medium but containing in addition 1·0 per cent glucose. Growth was continued for six to seven days after inoculation.

The alga was harvested by centrifuging at 950 *g* for 5 min. The centrifuged cells were then washed by repeated centrifuging from distilled water and finally resuspended in 30–40 ml. of *M*/15 phosphate buffer (*p*H 7·5). This two-hundredfold concentration ensured a thick active suspension of cells. Their density was approximately 4 million/mm.[2].

*Preparation of a concentrated, cell-free extract.* The concentrated suspension of cells was subjected[3] to a shearing strain of 20,000 lb./sq. in. This disrupted most of the cells, and a cell-free extract was obtained by removing unbroken cells and cell debris by centrifuging at 1,100 *g* for 30 min. The dark green, slightly turbid supernatant liquid was decanted and stored while the separated solid matter was discarded. In order to remove the free amino-acids already present in the extract, it was dialysed for 24 hr. at 4° C. in a collodion bag against a slow stream of *M*/15 phosphate buffer (*p*H 7·5).

The presence of transaminase systems in the extract remaining in the dialysis sac was then demonstrated as follows. The transamination systems investigated were those catalysing the transfer of amino-groups from various amino-acids to either pyruvic or α-keto glutaric acid. Eight amino-acids were used, including those that might be expected to be most active in transamination systems. The limited amount of extract available precluded the use of all the naturally occurring amino-acids. Oxalacetic acid was not used as an amino-group acceptor for this same reason, together with the fact that under the experimental conditions used it rapidly undergoes conversion to pyruvic acid, so giving anomalous results.

The *p*H at which the extract was buffered (7·5) has been demonstrated to be optimum for several transaminase systems in *Neurospora crassa*[3]. Transaminations catalysed by the *Chlorella* extract were demonstrated by following the production of glutamic acid or alanine formed from α-keto glutarate or pyruvate respectively, by means of chromatography. 0·5 ml. of the extract was pipetted into each of sixteen tubes. To each of eight of these, 0·25 ml. of *M*/10 sodium pyruvate was added, while 0·25 ml. of sodium α-keto glutarate was added to each of the other eight. Finally, 0·25 ml. of an *M*/10 *l*-amino-acid was added to each tube. Glutamic acid was not added to α-keto glutarate, nor was alanine used with pyruvate. Instead, 0·25 ml. of buffer was added, and these tubes then constituted the controls upon which the changes in the concentrations of glutamic acid and alanine could be based. A duplicate set of sixteen tubes was also prepared, one set being incubated at 25° C. for 3 hr. and the other for 24 hr. At the end of the incubation periods the reactions were stopped by the addition of 2 ml. of absolute alcohol to each tube, followed by slight warming. This precipitated the proteins and stopped all enzyme action.

After settling of the precipitates, 60 µl. of the clear supernatant was withdrawn from each tube in turn and applied as a spot to a sheet of Whatman No. 4 filter paper in the normal way. The chromatogram was developed for 24 hr. in phenol-ammonia, and, after drying, the amino-acids were located by the usual ninhydrin treatment. The relative amounts of glutamic acid and alanine formed from the respective keto-acid from different amino-acids were estimated by comparison of spot sizes and intensities. The accompanying table summarizes the results obtained; the maximum amount of transamination found for any amino-acid was not considered to represent more than 20 per cent of the *l*-amino-acid originally added.

| α-Amino-acid added | α-Keto glutarate added | | Pyruvate added | |
|---|---|---|---|---|
| | Glutamate formed at 3 hr. | Glutamate formed at 24 hr. | Alanine formed at 3 hr. | Alanine formed at 24 hr. |
| Aspartic acid | +++ | ++++ | — | +++ |
| Glutamic acid | | | ++ | ++++ |
| Alanine | ++ | +++ | | |
| Leucine | + ? | ++ | — | ++ |
| Valine | — | — | — | — |
| Arginine | — | + ? | — | — |
| Serine | — | + ? | — | + |
| Glycine | * | * | — | + |

* Glycine was not added to α-keto glutarate.

From an inspection of the table it is seen that in *Chlorella* those transamination systems involving either aspartic acid, glutamic acid, or alanine are the most active. These conclusions agree very well with those obtained in other work using higher plants or animal tissues.

Thanks are due to Dr. L. Fowden and Mr. P. J. Syrett for their helpful advice and criticism, and to Prof. W. H. Pearsall for his interest in the work. The work was carried out with the aid of a grant from the Department of Scientific and Industrial Research.

## Controlling Effect of Salts on the Activity of the Cytochrome Oxidase

ACCORDING to the theory of anion respiration[1], the activity of the cytochrome system is controlled by the activity (concentration) of movable salt anions in the surroundings. With the aid of a new spectrophotometric technique it has been shown that in living wheat roots the oxidation reduction balance of the cytochromes *a* (oxidase), *c* and *b* is moved towards a higher state of oxidation by a change of the medium from distilled water to salt solutions (potassium chloride or nitrate, calcium nitrate, etc.). On removal of the salts the cytochromes revert to a more reduced state. From the automatic recording of the time-course of the phenomena, it was clearly shown that the change in the oxidation-reduction balance of the cytochromes starts simultaneously with the absorption of the salt ions. The fundamental fact that the coenzymatic effect is exerted by salt anions was established by earlier investigations on the effect of salts on the cyanide-sensitive part of respiration[2]. It was shown that this part of respiration is enhanced only if anions are absorbed; absorption of cations only had no effect on it.

Measurement of the reaction kinetics of the cytochrome system of wheat roots shows an electron transference from a dehydrogenase system (*DH* = succinic dehydrogenase) to oxygen along the potential ladder $DH \rightarrow b \rightarrow c \rightarrow a \rightarrow O_2$. According to the theory, an electron cannot be transferred from one molecule to another unless the same quantity of electricity is moved in the opposite direction in the form of a movable anion. As regards roots, oxygen and anions are provided from the medium. The cytochrome oxidase is most probably present in the surface of the protoplasm[1] and catches anions simultaneously with the delivery of electrons to the oxygen molecules. By a similar exchange between anions and electrons the former are successively forwarded to the end of the potential ladder. As each step of the chain requires the presence of anions as coenzymes, it will be theoretically possible to demonstrate this activity factor at any of the isolated steps. Technically, the sequence cytochrome *c* → cytochrome oxidase → oxygen is quite simple, because in homogenized roots the normal anion respiration is rapidly brought to a standstill, whereas the oxidase remains active as shown from its rapid oxidation of added reduced cytochrome *c*. The following experiment may serve as an illustration.

100 mgm. dry weight of wheat roots from desalted seedlings three weeks old was ground in a porcelain mortar after adding 10 c.c. distilled water. 1·5 c.c. of this preparation was added to a solution of 0·02 per cent cytochrome *c* ('Sigma'), reduced with some dithionite and afterwards aerated. The oxidation was followed spectrophotometrically by observing the decrease of the difference in extinction between the wavelengths 550 and 560 mμ. After 5 min., 41 per cent of the cytochrome was oxidized. If 0·1 *M* potassium chloride was added to the preparation, 73 per cent of the cytochrome was oxidized in 5 min. Controls with 0·001 *M* hydrogen cyanide showed no oxidation. The figures correspond to an oxidation of 1 07 μgm. iron per hr. per 10 mgm. in the desalted material and an oxidation of 1·70 μgm. iron after addition of potassium chloride; thus there was an increase of 64 per cent due to the salt effect. Similar results were obtained with potassium nitrate. Desalting can also be brought about by treatment with anion-absorbing resin.

Simultaneous spectroscopic measurements on living roots showed a quantity of $3 \times 10^{-5}$ μmol. cytochrome oxidase per 10 mgm. dry weight. In the presence of salts, this quantity oxidized 1·7 μmol. iron in 1 hr., corresponding to a turnover number of *c.* 1,000 per min. In the absence of salts this number decreases to *c.* 600; but this is, of course, not a minimum value because salts are always to some extent still present in 'desalted roots' (cf. ref. 2). In other experiments the activity of the preparations nearly equalled the normal activity of living roots, showing[1] a turnover number of *c.* 1,700 per min. at 19° C. The roots used for these experiments showed an active salt absorption from 0·0005 *M* potassium chloride of 0·82 μmol. chlorine per hr. per 10 mgm., corresponding to $Q_{an}/Q_{O_2}$ = *c.* 0·9 if calculated from the directly determined oxidase activity. This value is quite in accord with determinations of the anion respiration of living roots (see ref. 2).

## Acetic Acid in Fresh Grass

EXPERIMENTS carried out in these laboratories[1] on the formation of volatile fatty acids in grass/water slurries showed that, whereas butyric and propionic acids were formed after the primary production of lactic acid had been stabilized, acetic acid was produced even before the lactic fermentation began. It is, of course, well known that acetic acid is formed during the silage fermentation, but it seemed surprising that it should be formed so speedily.

An examination of a slurry which had been standing for two hours showed that appreciable amounts of acetic acid were even then present, although tests for lactic acid by the *p*-hydroxy diphenyl test[1-3] gave negative results.

It was decided to experiment with fresh grass juice; for this purpose, samples of grass obtained from a plot adjoining the laboratory were immediately minced and the product squeezed through a linen cloth which had been washed in hot water and then dried. The grass juice was subjected to steam distillation according to the procedure of Scarisbrick[4] to isolate the total volatile fatty acids, and the distillate was submitted to gas chromatography according to the technique of James and Martin[5]. A definite yield (about 8 mgm. per cent of the grass dry matter) was obtained on each occasion, but no other lower fatty acid in the $C_1$–$C_{12}$ range was isolated.

So far as we are aware, such a finding has not previously been reported in the literature, and all that may be concluded at this stage is that acetic acid is present, either free or in a state of loose combination, in the grass. It is possible that it forms an intermediate in the tricarboxylic acid cycle.

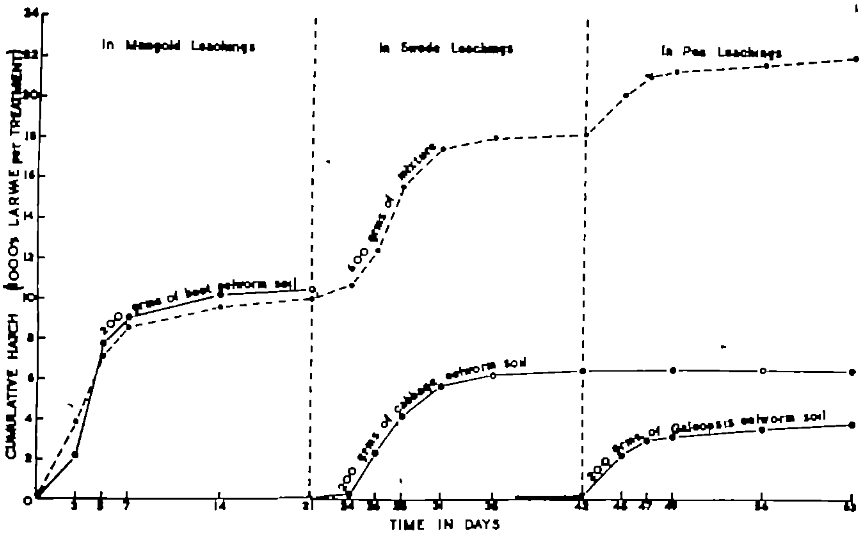
## Hatching Responses in Root Eelworms (*Heterodera* spp.)

RESULTS of recent investigations on larval emergence from cysts of root eelworms (*Heterodera* spp.) when exposed to plant root diffusates (using the methods evolved by Fenwick for potato root eelworm[1,2,4]) are summarized below.

Beet, potato and carrot root eelworms behaved normally in that they responded only in diffusates from hosts and from invaded plants. Cabbage root eelworm responded well in diffusates from hosts belonging to the genus *Brassica*, but did not respond to other cruciferous hosts or to non-hosts. *Galeopsis* and clover eelworms gave little or no response in diffusates from typical hosts, but responded readily to pea root diffusate. Hop eelworm responded to diffusates from three hosts, hop, hemp and small nettle (*Urtica urens*), and from the related plant *Parietaria diffusa*. Negligible responses in host and non-host diffusates were obtained with pea and oat root eelworms.

From the above findings, it seemed that a measure of success might be obtained in quantitative estimation of mixed populations of *Heterodera* species by exposing the cysts to a succession of plant root diffusates. In preliminary experiments of this nature reliable estimates (in terms of 'hatchable' larvæ) were obtained for a mixed soil population of beet, cabbage and *Galeopsis* eelworm cysts (see graph). A limitation of the method is that it is not applicable to those species which do not respond to root diffusates, for example, pea and oat root eelworms.

Applying Fenwick's technique for determining the shape of the hatching curve[3] to some of the above-mentioned species, it has been found that in all cases investigated (those of beet, cabbage, *Galeopsis* and



Hatching responses in a mixture of equal parts (by weight) of beet, cabbage and *Galeopsis* eelworm soils Method 1

hop eelworms) the curve is very similar to that found by Fenwick for potato root eelworm.

Certain of the plants investigated appear to have interesting possibilities for the biological control of root eelworms. Thus the root diffusate of the common weed swinecress (*Coronopus squamatus*) stimulates larval emergence from beet eelworm cysts and the roots are invaded by the larvæ, but apparently cysts are not formed[5]. The same is true of *Solanum nigrum* and potato root eelworm[6,7]. Diffusate from the urticaceous plant *Parietaria diffusa* stimulates emergence from hop eelworm cysts, but so far cysts have not been found on this plant when grown in infected soil. Pea diffusate causes a marked hatch of larvæ from *Galeopsis* and clover eelworm cysts, but the pea plant can scarcely be regarded as an efficient host of either eelworm. Similarity in the behaviour of these two eelworms suggests that they may be one and the same species.

## Toxicity of Chlorinated Phenyl Benzenesulphonates to Winter Eggs of the Fruit Tree Red Spider Mite, *Metatetranychus ulmi* (Koch)

The mite ovicidal activity of a number of substituted phenyl benzenesulphonates toward the eggs of the two-spotted spider mite, *Tetranychus bimaculatus* Harvey, was examined by Kenaga and Hummer[1], who found that substitution by bromine or, better, chlorine in the *para*-position in both phenyl rings led to compounds of considerable activity. By far the most active was 4-chlorphenyl 4-chlorbenzenesulphonate, and this has now been developed commercially in the United States. Afterwards, Kirby and McKinlay[2], using summer eggs of the fruit tree red spider mite *Metatetranychus ulmi* (Koch), and Read and Smith[3], using eggs of the glasshouse red spider mite *Tetranychus telarius* L., found that 4-chlorphenyl benzenesulphonate (CPBS) was at least as potent as 4-chlorphenyl 4-chlorbenzenesulphonate (CPCBS) toward both these eggs. Field experience in 1952 has shown that the former, especially when applied in conjunction with an acaricide, can give remarkably persistent control of the fruit tree red spider mite under English conditions, but considerable damage may occur in a year like 1952 to fruits of certain apple varieties, notably Worcester Pearmain.

Apart from dinitrophenols such as DNC and dinex, few chemicals so far tested have proved highly toxic to both the summer and winter eggs of the fruit tree red spider mite. Eaton and Davies[4] found both types of egg susceptible to *n*-dodecyl thiocyanate, azoxybenzene and the di*cyclo*hexylamine salt of dinex, but azobenzene was much less toxic to the winter than to the summer egg, and diphenyl sulphone showed an even greater disparity in the same direction. It is therefore of interest to record that the toxicities of a number of chlorinated phenyl benzenesulphonates are very similar toward both summer and winter eggs of this mite. In 1951, we tested 4-chlorphenyl 4-chlorbenzenesulphonate at 0·1 per cent, formulated with acetone (2 per cent), *cyclo*hexylamine dodecyl sulphate (0·05 per cent) and sodium di-octyl sulphosuccinate (0·02 per cent), using the rearing and dipping techniques described by Eaton and Davies[5], and found hatching to be almost completely prevented, even fewer eggs hatching than among those treated with 0·09 per cent diethanolamine salt of dinoseb.

Laboratory tests on March 12, 1952, were extended to phenyl benzenesulphonate and eight chlorinated derivatives (several of which appear to be new compounds), using the same techniques and formulation, except that the wetting agent was reduced from 0·02 to 0·01 per cent. The compounds used and their melting points are listed in the accompanying table, with the concentrations (which were equimolar), and the percentage mortalities corrected by Abbott's formula using the formulation control mortality as base-line. 4-Chlorphenyl 4-chlorbenzenesulphonate was also tested at three lower concentrations, and the results are included in the table.

It will be seen that four of the nine compounds tested possess considerable activity, and that the order of toxicity among the first four esters listed is similar to that established by Kirby and McKinlay[2] against the summer egg. This possession of winter ovicidal activity by promising summer ovicides may

| Chemical | Melting point (° C) | Percentage concentration | Percentage mortality ($c = 0$) |
|---|---|---|---|

* Not previously recorded.

well prove to be of considerable practical significance as regards the time at which they are applied in the orchard. In the past, the first application of summer acaricides and ovicides has been delayed until the hatching of the more resistant winter eggs is complete, a procedure which involves extremely careful timing for maximum effectiveness. It is conceivable that, using compounds possessing such well-developed activity to both types of egg, an earlier and more effective application might be possible. At the same time the undesirable effects on developing fruit which have been encountered might be avoided.

## Effects of Different Water-regimes on the Growth of Tomatoes under Glass

The relationship between the growth of glasshouse crop plants and the level of their water supplies is still uncertain. In order to investigate possible effects of soil moisture on the rate of growth and yield of tomatoes (varieties of *Lycopersicum esculentum* Mill.) under glass, tomato plants have been subjected to four different water-regimes for a continuous period of about five months with interesting results. During that time, the soil moisture in each treatment has been allowed to fluctuate only between field capacity and a predetermined level of dryness as indicated by the moisture tension at a depth of 15 cm. below the surface.

A glasshouse was subdivided into twenty-four plots by water-proofed brick walls which penetrated into the subsoil. Each plot was approximately 210 cm. × 180 cm. and contained a bed of about 20 cm. of coarse sandy loam top soil, overlying about 40 cm. of slightly heavier, well-drained, cultivated subsoil, which in turn rested on massive, well-structured but undisturbed Keuper marl. Plots were equipped with apparatus for the measurement of soil moisture, including laboratory and commercial models of soil tensiometers, the bulbs of which were buried variously at 15 and 45 cm. below the surface.

Early in March 1952 the beds were thoroughly flooded with water, allowed to drain and given a normal commercial dressing of base fertilizer. On March 31 they were planted up with uniform plants of the tomato varieties Ailsa Craig and Single Cross, ten plants of each variety being planted in each bed. During the next twenty-five days all plants were treated similarly and watered individually, until each had a well-developed root system.

On April 25, four different water-regimes were introduced and applied consistently for the rest of the season, each of the four treatments being replicated in six randomized blocks. In each treatment one plot, chosen at random, was used as the key plot to control the watering throughout the season of that treatment, that is, all six plots were watered when the tensiometer bulb embedded at 15 cm. depth in the key plot recorded a predetermined reading. The tensions, chosen arbitrarily, at which it was decided to apply water were 7, 15, 30 and 60 cm. of mercury for the four treatments respectively.

The approximate water deficit of each key plot at the selected tension was assessed by a rough calculation, and on each occasion when a plot was watered, sufficient water was applied to make good this deficit with the view of wetting the whole bed of soil approximately to field capacity. The volume of water applied per plot at each watering naturally varied at different times and from treatment to treatment, ranging from as little as 14 litres per plot on the wettest treatment early in the season when most of the roots were confined to a relatively shallow layer of soil, to as much as 318 litres per plot (8·4 cm. of water) in the driest plots towards the end of the season when the tomato roots had ramified through the whole bed of soil. Similarly, frequency of application of water varied widely, from almost daily watering of the wettest plots to approximately monthly applications to the driest plots.

With regard to other environmental factors, the plants were treated according to the rules of good husbandry throughout the season. All plots received the same total amount of nutrient, which was applied in solid form prior to watering and washed in. Treatments continued until early October, and it may thus be claimed that the plants were grown for about five months under four different and definable water-regimes.

Data regarding watering and yields are given in the accompanying table, in which all the figures refer

| Treatment | Irrigation data | | | Average yield per plant* | | | |
|---|---|---|---|---|---|---|---|
| | Tension at which water applied (cm. Hg) | Number of times water applied | Total amount of water applied (cm.) | Ripe fruit | | Total yield (incl. green fruit picked Oct. 4) | |
| | | | | Ailsa Craig (kgm.) | Single Cross (kgm.) | Ailsa Craig (kgm.) | Single Cross (kgm.) |
| *A* (Wet) | 7 | 136 | 53 3 | 3·4 | 2·6 | 4·2† | 3·2 |
| *B* | 15 | 17 | 37·8 | 3·2 | 2·2 | 3 8 | 2·6 |
| *C* | 30 | 9 | 32 0 | 3·1 | 2·2 | 3 5 | 2·5 |
| *D* (Dry) | 60 | 5 | 31 0 | 2·6 | 1·8 | 3 0 | 2·1 |

* Average of sixty plants for each variety in each treatment.
† Equivalent to a yield of 86 tons per acre at the spacing of plants in this experiment, excluding the space taken by the path down the centre of the house.

Significance at 2 per cent level ($P = 0·02$) :—
Ailsa Craig : *A* and *C* are significantly greater than *C* and *D* respectively. Single Cross : *A* and *C* are significantly greater than *B* and *D* respectively.

to the period from April 25, 1952 (when differential watering commenced), to October 4, 1952.

Since the level of watering was the main variable environmental factor under the conditions of this experiment, the results suggest that there was a strong correlation between the type of water-regime under which the plants were grown and the yield of ripe fruit produced, the wetter treatments tending to produce the higher yields. Other observations point to a similar positive correlation between the vigour of vegetative growth and the level of water applied. The distribution of roots in the soil was also affected by the water-regimes, the zone of greatest root development becoming progressively deeper in the drier treatments.

The results are of great interest when compared with those of other workers in this field. Martin[1] (working with *Helianthus annuus*), Heck[2] (working in Hawaii on sugar cane) and others have found that vegetative growth is retarded as moisture tensions rise, which is in accord with our own results on tomatoes. On the other hand, Singh and Joon, in India[3], and Molenaar and Vincent, in Washington[4], have shown that excessive application of water to tomatoes (growing out-of-doors) may reduce the yield of fruit. There may thus be an optimum moisture regime, in the region of field capacity, for the growth of tomatoes under glass.

We wish to express our appreciation of the help given by Mr. D. V. Crawford, of the Department of Agricultural Sciences, in connexion with determinations of soil moisture, pore space, etc.

## Use of the Warburg Respirometer to study Microbial Activity in Soils

THE respiratory activity of the micro-organisms in samples of soil, determined by estimating the evolution of carbon dioxide, has long been considered by soil microbiologists to be related to soil fertility[1,2]. Lees has recently described a modified Haldane respirometer for measuring oxygen uptake as the criterion for that activity[3]. Along somewhat similar lines, our own studies suggest that the Warburg constant-volume respirometer may prove a valuable tool with which to examine the activities of soil organisms in the breakdown of soil organic matter, or to determine the effect of various treatments in modifying the behaviour of soil organisms.

We have noted that, when air-dried soil is placed in Warburg vessels and moistened to 80–90 per cent of saturation, the daily rates of oxygen uptake may be related to time by the equation:

$$Y = F'/t^{m'},$$

where $Y$ represents oxygen uptake expressed in µl. per gm. of soil per hr., $F'$ and $m'$ are constants, and $t$ is time in days. This equation is derived from earlier forms reported by other workers[4,5]. $F'$ and $m'$ are derived by converting the equation to its logarithmic form:

$$\log Y = \log F' - m' \log t.$$

When $\log Y$ is plotted against $\log t$, a close fit to a straight line has, as a rule, been obtained for periods of two to three weeks; and it appears that observations taken for five or six days (the result for the first day usually being omitted) establish the line reasonably well. We are of the opinion that the Warburg method, combined either with graphs or regression-line values, makes possible a considerable reduction in the time required for determining respiratory activity in a soil.

By these procedures it was found that two soils, differing widely in their organic content (one being a 'muck' and the other a loam), gave $m'$ values which did not differ significantly, though their $F'$ values were quite distinct. Lees's results from an experiment with a tropical soil[3] yielded a regression line having a value of $m'$ similar to those obtained from our own soils, but a value of $F'$ much higher than any we have found.

Results of experiments using agents (disinfectants and heat) detrimental to the soil organisms suggest that our method may prove useful in determining the degree and duration of the interference of such agents with the biological equilibrium, since such treatments cause a marked deviation from the normal straight line; the latter reappears if and when adaptation to the treatment occurs.

A hypothesis seeking to explain the peculiar log rate – log time linear function is proposed. It is based upon the premise that the energy-yielding components of soil organic matter may be composed of two fractions, one being readily decomposable and the other less readily decomposable, and that the breakdown of each portion proceeds simultaneously according to first-order reaction rates. It is suggested that the apparent log rate – log time function arises because two superimposed first-order reaction rates tend to dominate the processes of decomposition. A more detailed account of our results is planned for a later paper.

## Influence of the Blood Glucose-Level on the Secretion of Adrenalin and Noradrenalin from the Suprarenal Medulla

CONSIDERABLE evidence has accumulated to show that hypoglycæmia, for example after insulin, leads to an increased liberation of adrenalin from the suprarenal medulla[1]. This effect may be regarded as a regulating mechanism for the blood sugar homœostasis.

In order to study this possible mechanism, the secretion of adrenalin and noradrenalin has been determined quantitatively in the venous blood after injections of glucose into cats anæsthetized with 'Nembutal'. The venous blood from the left suprarenal was collected by means of a polyethylene tube in the lumbar vein. The amounts of adrenalin and noradrenalin were determined by comparative tests on cat's blood pressure and hen's rectal cæcum[2]. The blood sugar was controlled regularly during the experiment.

On an average, the secretion of noradrenalin and adrenalin was 75 mμgm./min./kgm. (16 per cent adrenalin) at the beginning of the experiments. Glucose was infused in quantities from 0·1 to 0 8 gm./kgm. body-weight. The infusion of 0·1 gm./kgm. brought the secretion of adrenalin down to about 50 per cent, and 0·8 gm./kgm. to 7 per cent, of the secretion at the beginning. As the blood sugar decreased, the adrenalin secretion was found to increase proportionally. The noradrenalin secretion also decreased, but not to the same extent. Similar experiments were carried out on animals with a denervated suprarenal gland. The denervation brought the secretion down to about 25 mμgm./min./kgm. and this level remained unaffected by glucose. The blood glucose-level therefore causes a graded activation of the medullary secretion which is controlled by a nervous mechanism.

An attempt to localize the origin of the effect of glucose was made in the following way. The head of one cat (*A*) was cross-connected with the body of another (*B*). Glucose infused in *B* increased the blood sugar in the head of *A* and led to a decrease of the secretion from its suprarenal in spite of low blood sugar-level in this body. It therefore seems possible that glucose affects the secretion from the suprarenal medulla via some kind of chemoreceptor located centrally.

A further attempt to localize these supposed chemoreceptors was made by local injections of glucose in the hypothalamic region after injection of 0·05 ml. of a 5·5 per cent (isotonic) glucose solution. A marked decrease in the adrenalin secretion was noted in some of these experiments, while control injections of saline failed to produce this effect.

## Development of *Ostertagia circumcincta* in the Abomasal Mucosa of the Sheep

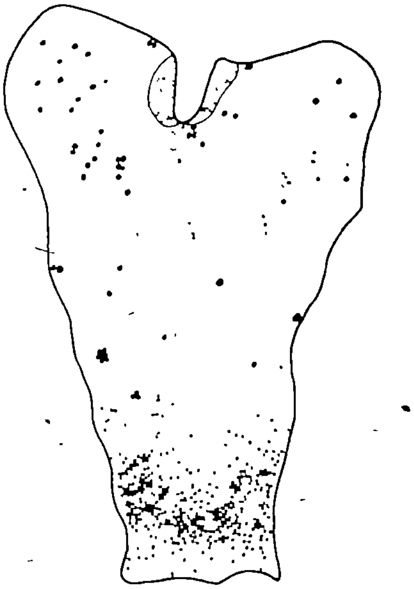
In the course of studies on *O. circumcincta* made at this laboratory, I have found that the phenomena of inhibited development and extended pre-patent period, described in *Nature* by Taylor and Michel[1] with reference to the lungworm *Dictyocaulus viviparus*, are also evident in the development of *O. circumcincta* in the abomasal mucosa of the sheep.

The literature on the 'histotropic phase'[2] of *O. circumcincta* is controversial. Threlkeld[3] found fourth stage larvæ in the mucosa four days after infection, and at eight days found adults and larvæ, both on the surface and within the mucosa. However, on the seventh day the presence of larvæ "for the most part unattached to the mucosa" suggested that larvæ may leave the mucosa, and afterwards repenetrate it. Contrary to this, Dickmans and Andrews[4] state that larvæ develop to maturity without leaving the shelter of the mucosa. The duration of the histotropic phase is not known, but Morgan, Parnell and Rayski[5] failed to find any evidence that it would extend over winter, and concluded that it was unlikely to be of importance in the epidemiology of ostertagiosis.

At this laboratory, worm-free sheep, housed under conditions which prevented accidental infestation, were dosed with 20,000 *O. circumcincta* larvæ each, and killed at intervals from three to eighty-four days later. Examination of the abomasal mucosa suggested that third stage larvæ penetrate the gastric pits on the third and fourth days. Thereafter larvæ may develop in one of several ways. Some may leave the mucosa after the third ecdysis and live on the surface. Others may grow within the mucosa but are able to leave it at any stage of development, although some may remain in the mucosa for a short time when mature. Yet other larvæ may fail to develop, and remain in the gastric pits and glands where they were found in sheep killed three months after the administration of infective larvæ.

The distribution of larvæ in the mucosa is shown in the accompanying drawing. The majority were found, singly or in pairs, in small nodules in the pyloric region, and on the valvulæ terminales around the cardiac orifice. In some sheep larvæ were found in the peptic region in groups of four to ten, usually in large flattened nodules which lie chiefly towards the edges of the spiral folds.

The extended histotropic phase may influence the effects of anthelmintics on *O. circumcincta*, since it is probable that parasites in the gastric pits and glands are protected. Preliminary observations suggest that phenothiazine is less effective against



Distribution of *Ostertagia* in the mucosa of the sheep's abomasum. Small dots represent one or two worms; large dots from four to ten worms

*O. circumcincta* than against *Trichostrongylus* spp.[6]. The extended pre-patent period observed in many of the sheep may be significant in the epidemiology of *O. circumcincta*. Larvæ acquired in any one month may not contribute to the contamination phase, as recorded by worm-egg counts, until several months later, but meanwhile may damage the mucosa.

The observations recorded here concern sheep which were given a single dose of larvæ. Whether a similar picture will be presented by sheep receiving repeated doses (as is assumed to occur in the field) is to be the subject of further investigation. Immunological phenomena may modify the pattern of development and may account for the findings of Morgan *et al.* that the number of larvæ occurring in the mucous membrane of the abomasum and small intestine were always surprisingly low.

A more detailed account of this work will be published elsewhere. The help of my colleague, H. McL. Gordon, is gratefully acknowledged.

## Differences in the Vitamin $B_{12}$ Content of Cow's Milk during the Last Month Indoors and the First Week at Pasture

THERE is not much information available regarding the amount of vitamin $B_{12}$ in the milk of individual cows[1]. The present work was undertaken to obtain a quantitative idea of the vitamin $B_{12}$ activity in cow's milk during the period of indoor feeding, and during the first week at pasture.

For assaying the vitamin $B_{12}$ potency of the milk, samples were taken twice a week from ten healthy animals of Friesian breed. The cows were milked twice a day, in the morning and in the evening. The morning and evening milk of each cow were analysed separately.

The determination is carried out by the microbiological method using the strain *Lactobacillus leichmannii* A.T.C.C. 4797. The response of the organism to vitamin $B_{12}$ activity was measured in terms of titratable acidity, and the experimental conditions necessary for obtaining consistent results were standardized. The results are shown in the accompanying table.

AVERAGE VITAMIN $B_{12}$ CONTENT OF MILK IN $\mu$GM. PER LITRE

| Cows | Morning milk | Evening milk | Daily production |
|---|---|---|---|
| Indoors | 5·96 | 6·65 | 6·31 |
| At pasture | 10·52 | 12·00 | 11·10 |

The vitamin $B_{12}$ level in the morning milk is in all cases evidently lower than that of evening milk. Indoors, the average production of milk in the morning was 10·98 lit., and in the evening 9·37 lit.; for animals at pasture, it was 9·53 and 6·90 lit. respectively for the first week. In the second week, the average production was the same as indoors. The morning milk showed an average vitamin $B_{12}$ content of 5·96 μgm. per lit. for cows indoors and 10·52 μgm. per lit. for cows at pasture, while the highest values observed were respectively 7·60 and 20·40 μgm. per lit. and the lowest 4·10 and 6·8 μgm. per lit. for morning milk indoors and at pasture.

The average vitamin $B_{12}$ activity in evening milk of cows indoors is 6·65 μgm. per lit. and of cows at pasture 12·00 μgm. per lit. Indoors, the maximum and minimum values found were 9·6 and 5·2 μgm. per lit. respectively, and at pasture 15·50 and 8·50 μgm. per lit. respectively. The daily production showed an average value of 6·31 μgm. vitamin $B_{12}$ per lit. for cows indoors and 11·10 μgm. per lit. for cows at pasture.

In agreement with the observation of de Heus[2], the increase in vitamin $B_{12}$ activity of milk of cows on grass is approximately twice that of cows indoors. All animals showed this increase in the first week on grass. It may be suggested that the micro flora of the rumen of cows at pasture changes to the advantage of the micro-organism producing vitamin $B_{12}$.

A detailed account of this work will be published elsewhere.

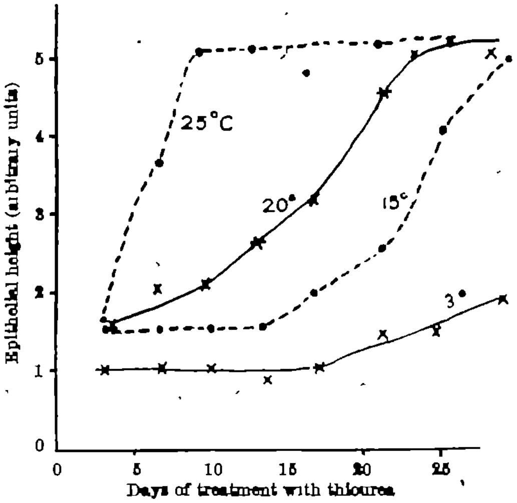
## Thyroid Activity in Teleosts

THE available evidence suggests that a calorogenic effect of the thyroid is doubtful in Teleosts. There has been a failure to modify the oxygen consumption, and therefore the heat production, by increasing or decreasing the amount of thyroid hormone available. Furthermore, the gland, as demonstrated in *Phoxinus lævis* and *Lebistes reticulatus*, unlike that of the higher animals, shows a regression with low external temperatures, and an increase of activity with high. This is emphasized by treatment with thiourea, for immersion of the fish in 0·05 per cent thiourea (changed twice weekly) results in an increase in epithelial height and a decrease in the amount of colloid present. These changes are more rapid when the treatment is applied at a constant high temperature. In this instance the activity has been measured arbitrarily by the epithelial height. For example, in October 1951, the gland of *Phoxinus lævis* showed a maximal structural effect after ten days at 25° C., whereas at 3° C. there was only a slight rise after three weeks (see graph).

It is unlikely, therefore, that the Teleost thyroid is functioning as a thermo-regulator, and it would not be expected to exert a calorogenic effect.

Terrestrial animals live in an environment of low thermal capacity and are exposed to great changes of external temperature; in addition, if the internal temperature becomes too great, there is a danger of death by desiccation, so that animals with a thyroidean type of thermo-regulator would have a selective advantage. The Teleost, in an environment of high thermal capacity, would not be subjected to such selection and so provides an example of physiological evolution.



This raises the question of the function of the thyroid in Teleosts. Some light may be thrown on this by the fact that thiourea-treated Teleosts can withstand much higher temperatures than usual. *Phoxinus laevis*, which, under conditions used, generally dies at 23° C., appears normal at 33° C., and *Lebistes reticulatus* shows a similar effect.

This fact, in addition to demonstrating a physiological effect of thiourea on Teleosts, suggests that there is yet another manner in which the thyroid can act as a mediator between the organism (in this case the fish) and its environment. Barrington and Matty[1] have recently shown a correlation between the thyroid and the reproductive organs; but it is possible that the thyroid exerts a more widespread influence, and treatment with thiourea may disturb the entire endocrine balance in the Teleosts in a manner unlike that in the higher vertebrates.

Further details of these experiments will be published elsewhere.

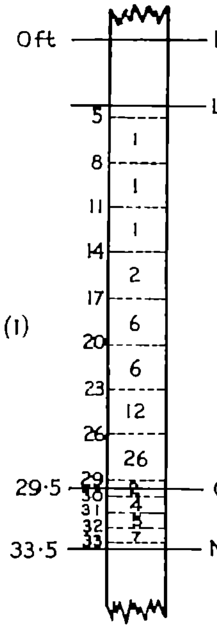
## Vertical Distribution of *Teredo norvegica*

THE literature dealing with the wood-boring bivalve, *Teredo*, is extensive. The majority of investigations, however, have dealt with floating structures and little attention has been paid to the problem of vertical distribution. During a recent investigation into an attack of *T. norvegica* on wooden structures at Loch Ryan, Scotland, information was obtained regarding the vertical distribution of this species.

In order to estimate the extent of the infection a wooden pile, 62 ft. long, was removed from a jetty and examined. This member of the structure had been in service for ten years but had been disturbed, with a resultant rise to 4 ft. above its original position, approximately three years before being pulled. The distribution of entry holes over the seaward face of this pile is shown in Fig. 1. There is an obvious increase with increase in depth down to the original mud-line at 29·5 ft. below M.T.L. This is followed by a sharp decrease at the original mud-line and a second increase down to the new mud-line at 33·5 ft. The number of *Teredo* holes in cross-sections of the pile shows a similar distribution. At 23·5 ft. there were 14, at 26·5 ft. 28 and at 29·5 ft. 52. Thus, within the vertical range covered by this pile, that is, down to 33·5 ft. below M.T.L., there is an increase in the intensity of infection with increase in depth.

There is little in the literature to explain this very marked distribution of *Teredo*. The larvae of *Teredo* tend to sink passively downwards whenever ciliary activity ceases. This tendency may possibly explain the distribution of *T. norvegica* observed at Loch Ryan. Observations on *T. pedicellata*, however, do not support this explanation. Doochin *et al.*[1] have suggested that the presence of a layer of silt near the mud-line would offer immediate protection from the mechanical effects of current. Unlike the cyprids of barnacles, the larvae of shipworms are not affected by the presence of a layer of silt. They are able to burrow through it. Isham *et al.*[2] have recently investigated the effect of light upon larvae of *T. pedicellata*. The results do not allow of any but tentative conclusions. It would appear from their experiments that settlement and subsequent boring may be expected to occur at a maximum under conditions of illumination of 160 ft.-candles. Illumination at the surface of open water on a bright day is of the order of 20,000 ft.-candles[3]. Thus, the figure of 160 ft.-candles represents deep shade.

The conclusions that light and the presence of a layer of silt may affect the vertical distribution of shipworm larvae would appear to agree with the distribution of *T. norvegica* observed at Loch Ryan. It is interesting to note, however, that the under-surfaces of horizontal structures suffered from a much heavier infection than did vertical surfaces at the same level. Similarly, an underwater survey by divers revealed that the raker piles, which are inclined at an angle to the vertical, were most heavily infected in the region shown in Fig. 2. This is the region of maximum shade.



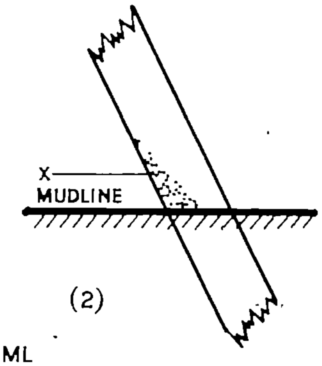


Fig. 1. Vertical distribution of entry holes of *T. norvegica* over the seaward face of a wooden pile. The measurements are given in feet below M.T.L. *NML*, new mud-line; *OML*, original mud-line

Fig. 2. Diagram of a raker pile near the mud-line to indicate the region most heavily attacked by *T. norvegica*. *X*, region of greatest attack

These observations suggest that the larvæ of *T. norvegica* tend to settle in increased numbers in dimly lit regions and that the presence or absence of a layer of silt is of little importance. More information is required, however, before the importance of light as a factor in determining the vertical distribution of *Teredo* can be accurately assessed.

## Life-history of *Gorgoderina vitelliloba* (Olsson)

AMERICAN species of the subfamily Gorgoderinæ (Trematoda) exhibit life-histories which appear to fall into two distinct groups. In the genus *Phyllodistomum*, the host into which the miracidium penetrates is a freshwater cockle of the family Sphæriidæ, and the cercaria passively enters a dragonfly nymph, where the metacercarial cyst is formed. Life-cycles of this nature have been determined by Goodchild[1] and others. In the second type of life-history, as exemplified by that of members of the genera *Gorgodera* and *Gorgoderina*, while the miracidial host is again a freshwater cockle, the metacercarial host is usually a tadpole. Goodchild[2], Krull[3] and Rankin[4] have determined experimentally life-histories of this type.

Ssinitsin[5] described the life-cycle of *Gorgoderina vitelliloba*, the only European species of its genus, and recorded the metacercarial host as being a dragonfly nymph. If dragonfly nymphs are the usual metacercarial host for this species, it would appear that the European species of *Gorgoderina* has a life-cycle similar to those of American species of *Phyllodistomum* and different from American species of its own genus. Joyeux and Baer[6], however, have described a cercaria, liberated from sporocysts developing in *Sphærium corneum*, which they believe to be the cercaria of *Gorgoderina vitelliloba*. These cercariæ when fed to tadpoles produced metacercariæ.

The purpose of this communication is to place on record the fact that in England I have found tadpoles of *Rana temporaria* to contain metacercarial cysts, which when fed to frogs and toads known to be free from *G. vitelliloba* gave rise to infestations with this parasite. In addition, I have completely determined the life-cycle of *G. vitelliloba* in the laboratory and found the miracidia to enter both *Sphærium* spp. and *Pisidium* spp., but more frequently the latter. Cercariæ, when fed to tadpoles of *Rana temporaria*, produced metacercariæ which were used for infecting the definitive hosts. It would appear, therefore, that *G. vitelliloba* in England has a life-cycle similar to that of American species of the genus.

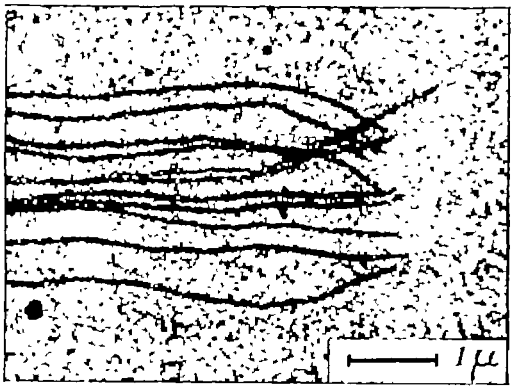
## Number of Fibrils in the Cilia of the Green Algæ

READERS of *Nature* who may have noticed the simultaneous appearance in the issue of February 14 of two independent communications[1,2] on plant cilia, one of them an abstract[2] of a paper of our own, could be misled by the accidents of context and wording into the belief that we are trying to use the internal structure of cilia as a basis for phyletic conclusions and that there is a fundamental difference between the green algæ in which Astbury and Saha[1] have found nine strands and all other plants in which there are eleven. To prevent such a mistake, it will perhaps be helpful to point out that the structure of the ciliary axis in all groups of plants and animals in which accurate work has been done appears to be identical. There is a precise and predetermined fibrillar structure composed of nine peripheral strands and a central pair (making eleven strands in all); there is also a superficial skin, some other components within the fibrils, and in certain cases at least there is a spiral winding between the peripheral fibrils and the core.

These facts are not controversial. Photographic evidence for all the more important plant groups possessing ciliated cells has been published by us in the *Journal of Experimental Botany* in a series of papers[3] during the past two years. Much of this is summarized in the report[4] of the 1951 Symposium of the Society of Experimental Biology, which also contains an electron micrograph showing the eleven strands in the green alga *Ulothrix*. Our most recent publication[5], on the moss *Sphagnum*, contains a diagrammatic reconstruction of the micro-anatomy of a cilium, the correctness of which as a generalized statement applicable to other groups, at least as regards the essentials of the transverse section, has been powerfully confirmed by the very beautiful thin sections prepared by Fawcett and Porter[6] of Harvard Medical School, who have communicated to us original prints of micrographs of transversely cut cilia in a frog, a mollusc and man, all of which show the same arrangement and number of strands. The eleven strands in animals have also been very clearly demonstrated among others by Jakus and Hall[7] in the cilia of *Paramecium* and by Grigg and Hodge[8] in the sperm tails of the fowl.

Where other numbers have been reported this is sometimes, and possibly always, due to imperfect observation or to imperfect material. Thus the two central strands often decompose more readily than the others or they may fall out, leaving only the peripheral nine. We have a paper passing through the press now[9] correcting an earlier mistake of our own (in the hind flagellum of *Fucus*) due to this cause. Astbury and Saha's figured specimen of *Polytomella*[1] (a colourless member of the Volvocales) is undoubtedly in the same condition. We append a micrograph of the green alga *Chætomorpha* which shows unequivocally that in a complete specimen the normal complement of eleven strands can quite easily be found in this group as in others.

No phyletic significance can, of course, be attributed to a character as widespread as this, and the only possible interpretation is in terms of functional or structural mechanics. Some aspects of these are discussed in our paper on *Sphagnum*[5] and others in a new paper[9] on the brown algæ which is in the press. The phyletic conclusions mentioned in the summary in *Nature* of Manton, Clarke, Greenwood



Electron micrograph of the distal end of a dismembered cilium of the green alga, *Chaetomorpha melagonium*, stained to show the number of fibrils without other details, and stripped from glass as described in Manton, Clarke, Greenwood and Flint (ref. 2). Philips electron microscope, 60 kV., unshadowed, magnification × 12,000

and Flint[2] depend on the characters provided by external appendages which in a limited number of plant groups (but not in animals, land plants or green algæ) are borne upon the cilia. This will be obvious to anyone familiar with our work as published, though the cross-reference to Astbury and Saha's article in the summary of our paper might otherwise be misleading.

The specimen figured was from a preparation made by A. D. Greenwood and B. Clarke from fresh material collected at Cullercoats by Dr. E. Nicolai in January 1952.

## Growth and Optical Properties of Stearic Acid Crystals

We have applied optical and interferometric techniques to stearic acid crystals ($CH_3(CH_2)_{16}COOH$) which were grown from a dilute solution in benzene of the compound. Tabular crystals were produced by slow evaporation of a drop of this solution placed upon a clean, cooled microscope slide. Many spiral features have been observed upon the basal planes by examining the silvered crystals under phase-contrast illumination. These are growth spirals in accordance with the dislocation theory of Burton, Cabrera and Frank[1].

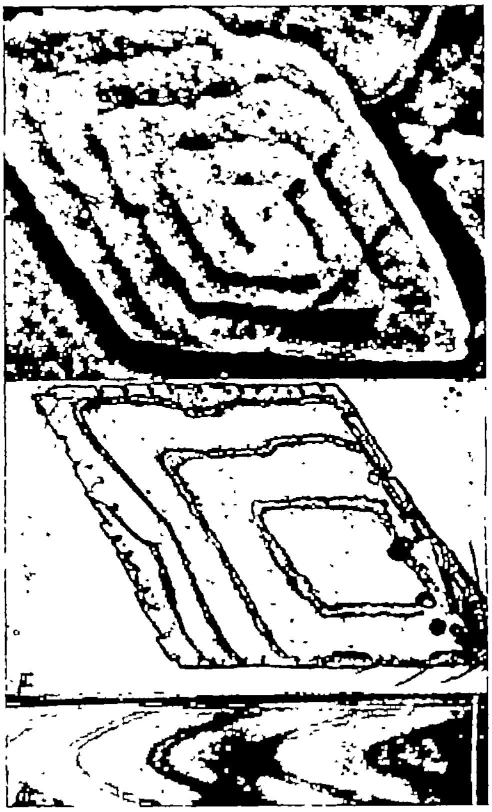
Fig. 1 (top) shows a growth spiral and a terminated line which can be interpreted as a ledge between the point of emergence of the screw dislocation on the underside of the crystal and the crystal boundary.

In addition, by the rapid evaporation of a drop of solution upon a warmed glass plate, circular spiral patterns have been obtained. These 'evaporation figures' have not been identified as growth spirals. The existence of oriented overgrowth has also been established.

Stearic acid is a monoclinic crystal with lattice parameters[2] $c = 48 \cdot 84$ A.; $\beta = 63° 38'$. Since the crystals were small (approximately 200 μ), the multiple-beam surface topography interference fringes generally obtained by matching the silvered crystal against a silvered optical flat could not easily be employed to determine the spiral step-height. It was found satisfactory to use the interferometric techniques formerly used with thin sheets of mica. The multiple-beam interference fringes produced by the internal reflexion between the two silvered surfaces of the crystal were thus found more convenient and accurate for the measurement of step-heights. We have made a large number of measurements and found that most of the step-heights are small integral multiples of 45 ± 5 A., which within experimental errors agree with the predicted X-ray repeat unit.

Fig. 2 (middle) illustrates the multiple-beam reflexion Fizeau fringes given by a doubly silvered crystal plate. The fringes are contouring a spiral so that they are parallel to the growth edges and, being very sharp, appear double owing to the birefringence of stearic acid. The two components are polarized at right-angles to each other. In Fig. 3 (bottom), the fringes of equal chromatic order[3] for a line section across the peak of this growth spiral are shown; the birefringence of the crystal is again obvious. These fringe patterns permit an accurate determination of the birefringence and also other optical properties of the crystal, in a manner already established.

A more detailed account of these investigations has been communicated elsewhere[4]. We thank Prof.



S. Tolansky for his interest and encouragement in this work. One of us (A. R. V.) wishes to express his thanks for the Imperial Chemical Industries Fellowship of the University of London, and to the University of Delhi for an extension of study leave.

*Note added in proof.* Since then, in addition to a step of unit height equal to 46·3 ± 0·8 A., we have measured steps which are odd-half integral multiples of the X-ray repeat unit.

## Radiation Induced by Alpha-Particles in Thin Films

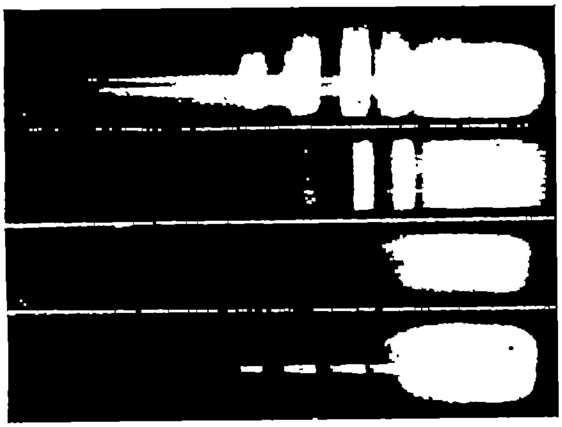
We have examined spectrographically the light emitted by thin films bombarded by α-particles[1]. The films were built up by evaporation on quartz slides to a thickness small compared with the range of the α-particles. The slides were mounted in front of the slit of a Hilger $f/4$ quartz spectrograph and exposed to a 25-mC. polonium source. Representative spectra, photographed on Eastman Kodak type II-0 spectroscopic plates, are shown in the accompanying photograph.

Spectrum (*a*) shows the continuum emitted by collodion extending, left to right, from about 230 mμ to about 470 mμ. The wave-length limits are set by the sensitivity of the photographic plate and not by the spectral energy distribution of the emitted light. Superimposed on the continuum are a number of bands which come from air molecules and from oxygen bound to the polonium[2]. At a slit-width of 0·2 mm. these bands are resolved into a series of lines listed in the accompanying table.

LIGHT FROM POLONIUM IN AIR

| Wave-length (mμ) | Rel. intensity | Wave-length (mμ) | Rel. intensity |
|---|---|---|---|
| 298 | 5 | 355 | 4 |
| 300 | 5 | 359 | 2 |
| 313 | 5 | 376 | 4 |
| 314 | 4 | 382 | 4 |
| 326 | 3 | 392 | 4 |
| 330 | 5 | 402 | 6 |
| 336 | 5 | 408 | 6 |
| 338 | 1 | 430 | 6 |

Spectrum (*b*) is obtained from a film of deoxyribonucleic acid of thickness corresponding to approximately 2 mgm./cm.$^2$. The film is transparent to the light from the polonium source, which again gives the characteristic superimposed bands. Spectrum (*c*) is from aluminium. Spectrum (*d*) comes from a thin film of gold (above) and a thin film of copper (below) separated by a narrow gap. Light from the polonium source can be seen through the gap on the quartz slide. It is clear, therefore, that films of collodion, deoxyribonucleic acid, aluminium, gold and copper, when bombarded by α-particles, emit radiation in a continuum from 230 to 470 mμ, the region of observation.



(*a*) Collodion; (*b*) deoxyribonucleic acid; (*c*) aluminium; (*d*) gold (above) and copper (below), separated by a narrow gap. Slit width, 2·5 mm. Exposure times, about 60 hr. for (*a*), (*b*) and (*d*), and 20 hr. for (*c*)

Dee and Richards[3] irradiated thin films of water on a quartz slide and found that chemical reactions were induced in solutions placed beneath the quartz. The chemical reactions were ascribed to quanta emitted from the bombarded water. To investigate the nature of these quanta we immersed the polonium source in water and made an eleven-day exposure. No radiation other than the lines listed in the table was observed. The failure to find such additional radiation from the water implies that any quanta emitted by the water must lie at wave-lengths shorter than 230 mμ, and hence beyond the limits of detection of our system.

We are indebted to Dr. R. E. Nusbaum, Mr. G. V. Alexander and Mr. F. W. Bishop for technical assistance.

## Structural Skeleton in a Bituminous Coal

Our previous experiments on the rheological properties of coal, determining Young's modulus by a resonant frequency method[1], internal viscosity by measuring the vibrational decrement at audio-frequencies[2], and breaking-strength by measuring the stress applied for rupture for various durations of load[3], have shown that variations of these properties with ash concentration in coal expressed by volume parts are linear.

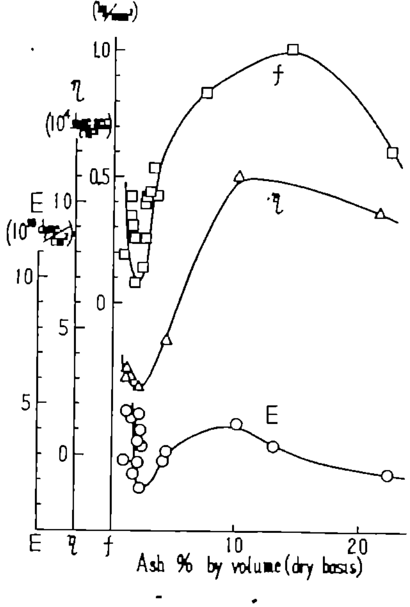
I have therefore suggested that in the caking coals ash particles 'solvate' coal molecules and form a micellar structure, as in the rubber–carbon black system. Although the proposed micellar structure is fundamentally different from that used by D. H.

Bangham *et al.*[4], it is believed that the physical picture presented can be used for interpreting the rheological properties and especially the caking phenomena. The state of ash in caking coal as an active 'filler' is not specified; but it is inferred that the active filler in general has strong affinity for the matrix molecules and is finely dispersed, so that the 'active' ash is likely to correspond to the inherent ash of coal.

Recently, we recognized interesting anomalies in these values for a Japanese bituminous caking coal, Takashima, with an average volatile matter of 38 per cent (dry ash-free), as illustrated in the graph; minima were shown in the range of 2 per cent of ash-volume concentration, and maxima in the 8–10 per cent range. These results seem to support the theory that the inorganic matter plays a significant part in the structure of coal and its properties. The linear relationship between the values and ash content is considered to be in the range of 2–10 per cent of ash for this sample.

It is well known in rubber science that elastic constant, viscosity coefficient and tensile strength at first decrease with loading with carbon black (up to 10 per cent by volume[5]), followed by an increase of these properties for greater loadings up to a point (30 per cent by volume[5]) where the stiffening ends by overloading. The similarity in variations of rheological properties between the two systems, with 'filler' and matrix, is interesting, despite the numerical differences in ranges of filler content. It may be suggested that the first minima at 2 per cent of ash content correspond to the state where the micellar spheres, in which the coal molecules are solvated by ash particles as nuclei, first touch each other, forming a sort of scaffolding, and the second maxima at approximately 10 per cent of ash content represent the point where the micellar spheres form a close-packed state.

Taking a sample with 10·13 per cent ash by volume of Takashima coal, the specific surface area was found by the iodine adsorption method[6] at 25·0° C. to be 9·51 × 10⁴ cm.²/gm. (dry basis) and the density in methanol was 1·24 (25·0° C.). Assuming the close-packed state of micellar spheres for the range of 10 per cent ash and that each micelle has an untruncated surface, the radius of the sphere was calculated as 2540 A., and the radius of the ash particles serving as nuclei was estimated as 1160 A.; these dimensions of ash are nearly the same as those of some kinds of carbon blacks. The micellar dimensions are expected to be largest for caking coals, because the solvation factors of molecules around ash are highest[1,2] and, as is widely recognized, the variation of the specific surface area with the rank of coals shows a minimum for the bituminous coal group.



Experimental results on the variations of rheological properties of Takashima bituminous coal: *E*, Young's modulus; *η*, internal viscosity coefficient; *f*, breaking strength

The detailed results of this investigation will be published in *Bull. Chem. Soc. Japan*, as part of an investigation of the rheology of coal. I am indebted to Mr. H. Tani for help in the experiments.

## Diffusion of Silicon in Ferrite

WE have recently carried out some measurements on the diffusion of silicon at low concentrations in ferrite at one temperature near to the melting point. Specimens (cylinders of ¼ in. diameter) were made of pure iron butt-welded to a 3–4 per cent silicon iron alloy. These were heated for differing times at the temperature 1,435 ± 5° C., cooled and sectioned along a plane perpendicular to the weld interface. The diffusion of silicon into the iron across the interface was measured by traversing the section with a spectrograph spark. By correcting for the finite size of the sparked zone and standardizing the spectrograph with samples of known silicon content, curves of silicon concentration versus distance were plotted. The diffusion coefficient of silicon was obtained by applying Fick's law and the result (mean of five determinations) was $D_\gamma = 1\cdot1 \times 10^{-7}$ cm.²/sec. The grain-sizes of the specimens were large enough to assume that at the temperature used the contribution of grain-boundary diffusion was small, and it is thought that overall error in $D$ should not be greater than ± 20 per cent.

The variation of $D$ with temperature may be calculated if Zener's theory[1] is assumed. Depending on whether vacancy or ring diffusion occurs, respectively, $D_\gamma = 16 \exp(-64{,}000/RT)$, or $310 \exp(-74{,}000/RT)$ cm.²/sec.

# FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

## Saturday, March 14

Botanical Society of the British Isles (at the Linnean Society of London, Burlington House, Piccadilly, London, W.1), at 2.15 p.m.—Annual General Meeting.

## Monday, March 16

Society of Chemical Industry, London Section (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 6.30 p.m.—Scientific Papers.

Royal Geographical Society (at 1 Kensington Gore, London, S.W.7), at 8.15 p.m.—Prof. W. Q. Kennedy, F.R.S.: "The Mountains of the Moon" (Mrs. Will Gordon Lecture).

## Monday, March 16—Wednesday, March 18

Institution of Electrical Engineers, Measurements Section (at Savoy Place, Victoria Embankment, London, W.C.2).—Symposium on "Insulating Materials".

## Tuesday, March 17

London Mathematical Society (at the Royal Astronomical Society, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Prof. T. Fort: "Boundary-Value Problems for Ordinary and Partial Linear Difference Equations".

Society of Chemical Industry, Crop Protection Panel of the Agriculture Group (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Dr. E. H. Turtle: "Rodenticides".

## Wednesday, March 18

Royal Sanitary Institute (at 90 Buckingham Palace Road, London, S.W.1), at 2.30 p.m.—Mr. H. A. Cox: "The Importance of Timber Preservation in the National Economy".

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C.2), at 2.30 p.m.—Mr. H. A. R. Binney: "Fifty Years' Work on Industrial Standards".

Geological Society (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Dr. R. G. S. Hudson and Mr. D. M. Martin: "The Structure of the Jebel Hagab Area, Trucial Oman".

Royal Meteorological Society (at 49 Cromwell Road, London, S.W.7), at 5 p.m.—Mr. B. J. Mason: "The Growth of Ice Crystals in a Super-cooled Water Cloud"; Mr. R. Wexler: "Theory of the Radar Upper Band"; Mr. I. C. Browne: "Precipitation Streaks as a Cause of Radar Upper Bands".

Royal Society of Medicine, Comparative Medicine Section (at 1 Wimpole Street, London, W.1), at 5 p.m.—Discussion on "Some Biological Aspects of Mucin".

Royal Statistical Society, Research Section (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 5.15 p.m.—Dr. C. A. B. Smith: "The Detection of Linkage in Human Genetics".

British Ornithologists' Union (at the Zoological Society of London, Regent's Park, London, N.W.1), at 6 p.m.—Annual General Meeting.

Royal Institute of Chemistry, London Section (joint meeting with the London Section of the Society of Chemical Industry, in the Large Chemistry Lecture Theatre, University College, Gower Street, London, W.C.1), at 6.30 p.m.—Dr. F. Sanger: "The Chemistry of Insulin".

## Thursday, March 19

Institute of Metal Finishing (at Charing Cross Hotel, Strand, London, W.C.2), at 2.30 p.m.—Inaugural Meeting of the Organic Finishing Group; at 3 p.m.—Mr. A. A. B. Harvey: "Problems of Paint Application"; at 4.30 p.m.—Mr. D. H. Lloyd: "Problems of Dip and Spray Painting".

Royal Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Scientific Papers.

Imperial College Chemical Society (in the Main Chemistry Lecture Theatre, Royal College of Science, Imperial Institute Road, London, S.W.7), at 5 p.m.—Prof. R. G. W. Norrish, F.R.S.: "Recent Studies in the Combustion of Hydrocarbons".*

Linnean Society of London (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Mr. Frank L. Hill: "The Natural History of the Monte Bello Islands".

Society of Chemical Industry, Microbiology Group (at the Medical Society of London, 11 Chandos Street, Cavendish Square, London, W.1), at 6 p.m.—Annual General Meeting; at 6.15 p.m.—Dr. H. S. Holden: "Microbiology and Crime".

Society of Chemical Industry, Road and Building Materials Group (at the Building Centre, Store Street, London, W.C.1), at 6 p.m.—Mr. D. B. Honeyborne: "Differential Thermal Analysis and its Application to the Study of Building Materials".

Oil and Colour Chemists' Association, London Section (at the Royal Society of Tropical Medicine and Hygiene, Manson House, 26 Portland Place, London, W.1), at 7 p.m.—Mr. W. A. Caldwell and Mr. J. Creasy: "The Effect of some Physical Properties of Nitrocellulose on Lacquer Performance".

Chemical Society (at Burlington House, Piccadilly, London, W.1), at 7.30 p.m.—Prof. J. R. Partington: Nernst Memorial Lecture.

Royal Society of Tropical Medicine and Hygiene (at the Royal Army Medical College, Millbank, London, S.W.1), at 7.30 p.m.—Laboratory Meeting.

## Friday, March 20

Society for Water Treatment and Examination (at the Laboratories, Metropolitan Water Board, New River Head, Rosebery Avenue, London, E.C.1), at 10 a.m.—Annual General Meeting; Scientific Papers.

Royal Microscopical Society, Industrial Section (joint meeting with the Industrial Spectroscopy Group of the Institute of Physics, the Optical Group of the Physical Society and the Physical Methods Group of the Society of Public Analysts and other Analytical Chemists, at King's College, Strand, London, W.C.2), at 2.30 p.m.—Symposium on "Developments in Microscopical Methods".

Institute of Navigation (at the Royal Geographical Society, 1 Kensington Gore, London, S.W.7), at 5 p.m.—Dr Samuel Herrick: "Dead Reckoning in Space".

Institution of Mechanical Engineers (joint meeting with the Applied Mechanics Group, at Storey's Gate, St. James's Park, London, S.W.1), at 5.30 p.m.—Dr. J. H. Lamble and Dr. Salah E. A. Bayoumi: "A Room Temperature Photoelastic Technique for Three-dimensional Problems"; Mr. J. D. C. Crisp: "The Use of Gelatin Models in Structural Analysis".

# APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Principal Scientific Officer at the Atomic Energy Research Establishment, Harwell, to take charge of small group engaged in problems of heat transfer, and special problems arising in development of nuclear energy for power purposes, involving design of special experimental apparatus—The Civil Service Commission, Scientific Branch, Trinidad House, Old Burlington Street, London, W.1, quoting S.4190/53 (March 19).

Senior Scientific Officers (with a first- or second-class honours degree in chemical engineering, or in chemistry or engineering with postgraduate diploma in chemical engineering, or equivalent qualification) for pilot plant and process development; a Senior Experimental Officer or Experimental Officer (with a comprehensive experience of chemical plant operation and control); and a Senior Experimental Officer to assist in design, construction and operation of apparatus to be used in development of methods of handling liquid metals, to supervise running of test rigs and to train junior staff; in the Chemical Engineering Division of the Atomic Energy Research Establishment, Harwell—The Civil Service Commission, Scientific Branch, Trinidad House, Old Burlington Street, London, W.1, quoting S.4188/53 (March 19).

Experimental Officer to investigate rejection tests for raw farm milk (extensive laboratory experience is necessary with, preferably, a degree or equivalent qualification in bacteriology or chemistry)—The Secretary, National Institute for Research in Dairying, Shinfield, Reading, quoting Ref. 53/5 (March 21).

Lecturer (with good honours degree in chemistry and appropriate teaching experience) in the Department of Chemistry and Biology, to teach physical chemistry, with some inorganic chemistry, to final degree standard, and a Lecturer (with good honours degree in physics and appropriate teaching experience) in the Department of Physics and Mathematics, to teach physics to final degree standard—The Principal, Acton Technical College, High Street, Acton, London, W.3 (March 21).

Senior Agricultural Economist in the Agricultural and Marketing Branch of the Department of Agriculture and Lands, Southern Rhodesia Government—The Secretary, Rhodesia House, 429 Strand, London, W.C.2 (March 21).

Statistician (part-time) in the Health and Welfare Department—The Medical Officer of Health, Willowbank House, Willowbank Road, Aberdeen (March 21).

University Assistants in Genetics, Civil Engineering, Animal Husbandry and Preventive Medicine (chemist or biochemist)—The Secretary of University Court, The University, Glasgow (March 21).

Assistant Lecturer in Chemistry—The Registrar, College of Technology, Manchester 1 (March 23).

Assistants (with first- or second-class honours degree in electrical or mechanical engineering or in physics and, preferably, some research experience) on the scientific staff of the B.E.A. Research Laboratories at Leatherhead—The Director of Establishments, British Electricity Authority, British Electricity House, Winsley Street, London, W.1, quoting AE/337 (March 23).

Educational Psychologist—The Chief Education Officer, Education Office, Margaret Street, Birmingham 3 (March 23).

Plant Pathologist (Scientific Officer grade) and an Assistant Experimental Officer—The Secretary, National Vegetable Research Station, Wellesbourne, Warwick (March 23).

Physicist to assist in the general work of the Physics Department—The National Coal Board, Central Research Establishment, Stoke Orchard, Cheltenham, quoting TT/595 (March 25).

Assistant Agricultural Economist (with a degree in economics or agriculture with economics)—The Registrar, The University, Manchester 13 (March 28).

Cytologist to the Division of Plant Industry, Canberra—The Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2 (March 28).

Dental Research Fellow—The Dean, Guy's Hospital Medical School, London, S.E.1 (March 28).

English Electric Company Research Fellowship in Aeronautics—The Secretary of University Court, The University, Glasgow (March 28).

ENTOMOLOGIST (Grade II), an ENTOMOLOGIST (Grade I), an AGRONOMIST (Grade II), an AGRONOMIST (Grade I), a PLANT BREEDER (Grade II), a PLANT BREEDER (Grade I), and a SOIL SURVEY OFFICER (Grade I) in the Department of Agriculture, Stock and Fisheries, Papua and New Guinea—The Official Secretary, Australian High Commissioner's Office, Australia House, Strand, London, W.C.2 (March 28).

LECTURER IN BIOCHEMISTRY—The Registrar, The University, Sheffield (March 28).

SENIOR GEOLOGIST (with a degree in science or engineering, and some experience in prospecting for mineral resources, preferably in the United Kingdom) to act in a general advisory capacity—The National Coal Board, Establishments (Personnel), Hobart House, Grosvenor Place, London, S.W.1, quoting TT/302 (March 28).

ASSISTANT LECTURER IN MATHEMATICAL STATISTICS—The Registrar, The University, Manchester 13 (March 31).

H.M. INSPECTORS (with appropriate professional qualifications and teaching, and practical experience desirable in agriculture, mechanical engineering, mining, architecture, building or management studies)—The Secretary (Inspectors' Section), Ministry of Education, Curzon Street, London, W.1 (March 31).

JOHN MURRAY TRAVELLING STUDENTSHIP IN OCEANOGRAPHY AND LIMNOLOGY—The Assistant Secretary, Royal Society, Burlington House, Piccadilly, London, W.1 (March 31).

LECTURER (with special interests in soil science or plant nutrition) IN AGRICULTURAL CHEMISTRY, and a LECTURER (with special interests in some branch of electrochemistry) IN CHEMISTRY—The Secretary of University Court, The University, Glasgow (March 31).

MEDICAL STATISTICIAN to the Nuffield Department of Industrial Health—The Professor of Industrial Health, King's College, Newcastle-upon-Tyne (March 31).

ANIMAL GENETICIST (with a degree in agriculture and at least two years postgraduate study of animal genetics) in the Department of Agriculture, Nigeria—The Director of Recruitment, Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1, quoting CDE.03/14/012.

ASSISTANT (graduate in medicine, biology, psychology, sociology, or any other social science) IN THE DEPARTMENT OF PUBLIC HEALTH AND SOCIAL MEDICINE—The Secretary, The University, Edinburgh.

ASSISTANT CHEMIST (B.Sc., preferably with power station experience), ELECTRICAL ENGINEERS, MECHANICAL ENGINEERS (Grades I, II and III), and a CIVIL ENGINEER—The Liaison Officer, Electricity Corporation of Nigeria, 11 Manchester Square, London, W.1.

ASSISTANT EXPERIMENTAL OFFICER at the Atomic Energy Research Establishment, Harwell, to abstract and subject-index scientific literature, and to supply information in response to inquiries—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting F.49/53A.

ASSISTANT MANAGER (Pile) at Sellafield, to be responsible for physical aspects of atomic pile operation and associated nuclear calculation—The Ministry of Supply, Division of Atomic Energy (Production), Risley, Warrington, Lancs, quoting 427.

ASSISTANT METEOROLOGIST for the British Caribbean Meteorological Service—The Crown Agents for the Colonies, 4 Millbank, London, S.W.1, quoting M.33526.E.

ASSOCIATE PROFESSOR OF CHEMISTRY (Organic), and an ASSOCIATE PROFESSOR OF CHEMISTRY (Physical)—The Registrar, Memorial University of Newfoundland, St. John's, Newfoundland, Canada.

BIOCHEMIST—The Group Secretary, Nottingham No. 2 Hospital Management Committee, Sherwood Hospital, Hucknall Road, Nottingham.

CHEMIST/ASSAYER (with an honours degree in chemistry) in Northern Rhodesia, to carry out assays and analyses of ores, minerals and rocks in the laboratory of the Geological Survey Department—The Director of Recruitment, Colonial Office, Great Smith Street, London, S.W.1, quoting 27106/57/52.

ELECTRICAL ENGINEERS and PHYSICISTS for the SCIENTIFIC OFFICER grade (Ref. A.5/53A) and EXPERIMENTAL and ASSISTANT EXPERIMENTAL OFFICER grades (Ref. A.6/53A) for research and development work on radio and electronic equipment in the Radar, Physics and Engineering Departments of the Telecommunications Research Establishment, Malvern—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting the appropriate Ref. No.

ENGINEER to the Ministry of Supply at Christchurch, to take charge of section engaged on design and development of electrical equipment for Royal Engineers—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting D.74/53A.

ENGINEER to the Ministry of Supply at Woolwich, to organise, administer and control small production plant for manufacture of electro-mechanical equipment, plastics and woodwork—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting C.432/52A.

ENTOMOLOGIST IN THE COLONIAL INSECTICIDE RESEARCH UNIT at the Ministry of Supply Chemical Development Experimental Establishment at Porton, Salisbury, to conduct research on entomological problems relating to the application of insecticides—The Under-Secretary of State, Research Department (S 610), Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1.

FISHERIES OFFICER (with a degree or diploma in zoology or allied subject and some experience of marine biology and fishing craft) in Gambia—The Director of Recruitment, Colonial Office, Great Smith Street, London, S.W.1, quoting CDE.65/12/01.

GAME WARDEN (with an honours degree in natural science and aptitude for field observation), Federation of Malaya—The Director of Recruitment, Colonial Office, Great Smith Street, London, S.W.1, quoting CDE.152/60/01.

GENETICIST AT THE FISH CULTURE RESEARCH AND TRAINING INSTITUTE, Federation of Malaya, to study genetics of pond-reared fish—The Director of Recruitment, Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1, quoting CSC.65/60/02.

GEOLOGISTS (with first- or good second-class honours degree in geology) in Malaya, for investigations of mineral resources and detailed geological mapping—The Director of Recruitment, Colonial Office, Great Smith Street, London, S.W.1, quoting CDE.106/60/03.

HEAD OF THE DEPARTMENT OF HOP RESEARCH, and a PLANT BREEDER IN THE DEPARTMENT OF HOP RESEARCH—The Registrar, Wye College, Wye, Ashford, Kent.

HEAD OF THE SPINNING DEPARTMENT—The Director of Research, British Cotton Industry Research Association, Shirley Institute, Didsbury, Manchester 20.

MATHEMATICS LECTURER in the Institute of Education, Bakht er Ruda—The Sudan Agent in London, Sudan House, Cleveland Row, London, S.W.1, endorsed 'Mathematics 1017'.

PHYSICAL CHEMIST for work on the oxidation of cellulosic materials, a PHYSICIST (with mathematical leanings) to continue experimental and theoretical work on fibre assemblies, and PHYSICISTS (10, with sound research training) for research work on problems arising out of the normal textile operations—The Secretary, British Rayon Research Association, Barton Dock Road, Urmston, Manchester.

PHYSICIST (with first- or second-class honours degree or equivalent in physics) at the Atomic Energy Research Establishment, Harwell, for X-ray analyses—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.46/53A.

PHYSICIST or ELECTRICAL ENGINEER at a Ministry of Supply Design Establishment near Sevenoaks, for development of V.H.F. oscillators and amplifiers or design of amplifiers for special purposes (circuit techniques involving time bases, trigger circuits, etc.)—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting A.22/53A.

PHYSICISTS (1) for operational research in wool textile mills, (2) for research on woollen carding and spinning processing and design of machinery, (3) for work on physical properties of fibres and fibre assemblies, and (4) for weaving research (honours degree men preferred for all posts, and essential for No. 4)—The Wool Industries Research Association, Torridon, Headingley, Leeds 6.

PHYSICISTS or CHEMISTS (with honours degree in physics or chemistry, or A.I.Inst.P. or A.R.I.C., or equivalent) for nuclear radiation protection duties in the Health Physics and Safety Department at Windscale Works, Sellafield—The Ministry of Supply, Division of Atomic Energy (Production), Risley, Warrington, Lancs, quoting 430.

PRINCIPAL SCIENTIFIC OFFICER at a Ministry of Supply establishment, Aldermaston, to direct and control the design of electronic equipment and electro-mechanical devices of a varied nature—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting D.64/53A.

PROTOZOOLOGISTS (with first- or second-class honours degree in zoology or zoology and botany) for research on the ciliate protozoa of ruminants and protozoan-bacterial interrelationships—The Secretary, Rowett Research Institute, Bucksburn, Aberdeenshire.

RESEARCH ASSISTANT (with a university degree) to aid and initiate researches in the DEPARTMENT OF AERONAUTICAL ENGINEERING—The Registrar, The University, Southampton.

RESEARCH ASSISTANT IN THE DEPARTMENT OF APPLIED CHEMISTRY—The Secretary, Northampton Polytechnic, St. John Street, London, E.C.1.

RESEARCH ASSISTANT (with honours degree in biology with experience of or inclination towards mathematical aspects of biological problems) IN THE DEPARTMENT OF TSETSE CONTROL, Gold Coast, to compile and analyse data on tsetse incidence with the purpose of evaluating the necessity for various control methods and of studying the biology of tsetse species in order to develop new control methods—The Director of Recruitment, Colonial Office, Great Smith Street, London, S.W.1, quoting 27059/311.

RESEARCH ASSISTANT TO UNIVERSITY BIOCHEMIST, to supervise routine clinical work of the Biochemical Laboratories, Addenbrooke's Hospital, Cambridge—The Professor of Biochemistry, Department of Biochemistry, Tennis Court Road, Cambridge.

RESEARCH DIRECTOR (university graduate with honours degree in physics or textiles, considerable practical experience in the cordage or textile industry, and well versed in spinning problems) to establish and undertake research in the United Kingdom into the utilization of sisal fibre, with special reference to ropes and cordage—The Secretaries, Overseas Sisal Research Committee, 10 Old Jewry, London, E.C.2.

RESEARCH FELLOWSHIP FOR WORK IN THE APPLIED BIOCHEMISTRY DEPARTMENT on the contributions of energy, amino-acids and vitamins by cereals to the nutrition of non-ruminant animals—The Secretary, Rowett Research Institute, Bucksburn, Aberdeenshire.

RESEARCH OFFICER (chemist or chemical engineer, with first- or second-class honours degree or A.R.I.C.) for work concerned initially with the processing of fibrous raw materials and recovery or disposal of waste products—The Director, British Paper and Board Industry Research Association, Welcomes Road, Kenley, Surrey.

SENIOR PHYSICIST (with an honours degree in physics, and previous hospital physics experience)—The Medical Director, Hogarth Radiotherapeutic Centre, General Hospital, Nottingham.

SHIFT MANAGER (with honours degree in chemistry or chemical engineering, A.R.I.C. or A.M.I.Chem.E., or equivalent) with managerial experience in a large chemical factory, and thoroughly conversant with modern methods of dealing with highly corrosive materials, inflammable solvents, and toxic hazards, AT THE ATOMIC ENERGY FACTORY at Salwick—The Ministry of Supply, Division of Atomic Energy (Production), Risley, Warrington, Lancs, quoting 426.

STATISTICIANS (with first- or second-class honours degree in statistics, or in mathematics, economics or other appropriate main subject combined with statistics) IN THE COLONIAL SERVICE—The Director of Recruitment, Colonial Office, Great Smith Street, London, S.W.1, quoting CDE.59/02.

UNIVERSITY GRADUATES and QUALIFIED TEACHERS (mainly with qualifications in mathematics, science (physics, chemistry, metallurgy) or engineering), for Short Service Commissions in the Instructor Branch, Royal Navy—The Director (P), Naval Education Service, Admiralty, London, S.W.1.

ZOOLOGIST (male, university graduate with first- or second-class honours) for general and experimental work on marine plankton—The Director, Marine Station, Millport, Isle of Cumbrae.

# COUNCIL FOR THE PROMOTION OF FIELD STUDIES

THE annual report of the Council for the Promotion of Field Studies for 1951–52 maintains the high standard, in presentation and in interest, which we have already, within ten years, come to expect of the Council's reports. With the director's report, and those of the wardens and the accounts, are printed four articles illustrative of the work being done through the field-centres and which will interest a wide range of scientific and professional workers no less than amateurs. They cover excavations in East Suffolk, the aims and methods of geographical field-study developed at Juniper Hall under Prof. S. W. Wooldridge's guidance to train students in the art of looking at country, bird navigational studies on Skokholm Island and the vegetation of Malham Moor.

These articles testify both to the value of the educational work being carried out at the centres and to the potentialities of the centres for the advancement of scientific work. As such they have a fit place alongside the annual report, though the main importance of the document as a whole must lie in the frank account of the activities of the Council and the needs and difficulties of the centres given by the director and his wardens. It is abundantly clear from these plain records how much is due to the enthusiasm and untiring efforts of the director and wardens, the president (Sir Arthur Tansley), the successive chairmen of the Executive Committee (Prof. W. H. Pearsall and Prof. S. W. Wooldridge) and other officers, that the Council has brought its affairs through a critical year to a hopeful issue and kept open its opportunities, alike for science and the amateur scientist.

There may not be in Britain the myriad of voluntary endowments for scientific and other social purposes that characterizes the United States and to which Dr. R. B. Fosdick has directed attention in his recent book on the Rockefeller Foundation. Nevertheless, to a modest degree, the Council for the Promotion of Field Studies undoubtedly provides already in its field-study centres not merely educational opportunities but also potential growing points for scientific work, and it does so partly through voluntary effort. To an increasing extent the maintenance, still more the expansion, of its work depends on further financial support from voluntary sources, and the clear but eloquent exposition of the Council's claims in this report should be sure of sympathetic reception, particularly by scientific workers in Great Britain.

Prof. Wooldridge points out in his foreword to the report that, in accordance with the Ministry's declared intention throughout that the field-centres should become self-supporting, the Ministry of Education's grant is to be reduced in future by at least £3,000 annually from the £8,000 received during 1951–52. This necessitated drastic economies during 1952, including the closing of the central office and severe cuts at the field-centres, three of which are without a full-time assistant warden. In spite, however, of considerable strain and anxiety, a full season was worked at the field-centres with bookings exceeding those for 1951: 900 at Dale Fort and Skokholm; nearly 800 at Flatford Mill; 923 at Juniper Hall; and 990 at Malham (slightly less than in 1951). With the new charge of five and a half guineas weekly, continued support from the universities, an increasing number of subscribers and, more recently, some generous grants from industrial organizations, the Council managed to achieve a small balance of income over expenditure.

---

* Council for the Promotion of Field Studies, 1951–52. Pp. 52. (The Director, F. H. C. Butler, Ravensmead, Keston, Kent.)

Besides the reassurance thus given by the experience of the 1952 season, the Council has been registered as a 'charity', which offers the benefit of remission of income tax on covenanted donations additional to the minimum membership subscription. The first large grant under this arrangement was one given by Imperial Chemical Industries, Ltd., which will increase the Council's income from voluntary sources by £750 annually. Besides an anonymous donation of £500 and contributions of £250 (for Malham) from the Albert Reckitt Charity and £250 from Messrs. Fisons of Ipswich, the financial position has been strengthened by closer co-operation with local-authority associations. To facilitate this, the modification of the Council's articles of association was approved at an extraordinary general meeting on December 11, 1952, and in consequence it is anticipated that some help in the way of capital grants may be forthcoming from interested authorities to permit the improvement of the amenities and scientific equipment of the field-centres, particularly Juniper Hall and Dale Fort. The report acknowledges a generous response by some Welsh counties to a recent appeal for capital grants made from Dale Fort itself.

Apart from this question of capital grants, the director's report emphasizes that the maintenance costs of the field-centres are unlikely to be met solely by securing increased numbers of students, even at the higher weekly charges. Additional income from voluntary sources is urgently required, and the two main purposes for which the director suggests such funds are required are most likely to be served effectively if the Council retains the character of a voluntary body. First and foremost, it is necessary to increase the present meagre allocation of scientific staff at the field-centres, both to relieve pressure on the present minimum staff of two throughout the busy part of the season, and to free the staff to undertake those special researches and organize those long-term investigations for which their special qualifications and the unique position of the field-centres together fit them, and which are fundamental to the intellectual life of the centres. Secondly, the Council requires freedom to experiment by introducing courses which should undoubtedly be held but may not necessarily, when first introduced, attract those students who give the best results in term of economics.

It is unnecessary to recapitulate here what was said in these columns two years ago (cf. *Nature*, 167, 1041; 1951) as to the value to Britain's economy to-day of the ecological studies and the field-work which the Council is so well equipped to foster. The present report shows how ably the Council has maintained that work and its potentialities in spite of acute financial difficulties. That record, with Mr. F. H. C. Butler's convincing exposition of the reasons why it is important that the Council should remain a voluntary body and a movement, and not become an institution entirely dependent on State support, warrants the hope that there will be a generous response to this fresh appeal for support from voluntary sources.

One particular appeal is made in this report which deserves a generous response from the smaller industrial firms, as well as from local societies and institutions and private individuals, whether scientific or not. Two years ago, the Council initiated a Bursary Fund for assisting meritorious students, of all ages, who would otherwise be unable to afford the fees for working at the field-centres. During the year a grant of £400 was received from Mrs. F. E. Thornton, widow of the ornithologist C. E. Thornton, who knew and loved the Malham moors, to be invested for this purpose. Grants of £100 for the same purpose have been received from the Thomas Wall Trustees and the Worshipful Company of Grocers, and the steady accretion of this Fund by such and smaller gifts would enable the field-centres to take in each year a number of keen young students who could not otherwise visit them, and who are the most likely to undertake the important advanced work.

Hope for a generous response to this and the more general appeal of the Council for voluntary financial support is encouraged by the degree of co-operation which has already been established between the Council and representatives not merely of the local education authorities but also of the universities and learned societies. In the active and growing amateur and professional membership of the Council, there is room for an increasing number of scientists, who, no matter in what scientific discipline they have been trained, should appreciate the importance of a clear and widespread understanding of ecological problems in this era of critical relations between population and food supply and other natural resources. It may well be that this educational aspect of the Council's activities is even more important than its scientific work; but, on either count, scientists should not be less generous than industry or their fellow citizens in responding to this appeal, either personally or corporately through societies or institutions with which they are connected.

## CONIFERS UNDER THE POCKET-LENS CAMERA

**Conifers in Britain**

An Illustrated Guide to Identification. By B. Alwyn Jay. Pp. 47+136 plates. (London: Adam and Charles Black, Ltd., 1952.) 35*s*. net.

IT is useful at the outset to realize what this book is not. In spite of its sub-title it is not really a guide to the identification of the conifers growing in Britain, in the sense of being a full guide. It does not pretend to compete with such well-known manuals as Dallimore and Jackson's "Handbook" or Jackson's adaptation of it; for, in any good arboretum, a wide range of conifers would be found which are not even named in this book.

Nevertheless, within its scope, this is an interesting and valuable production and, to anyone who has also dabbled in photography, will be, in many ways, a delight. The volumes of Clinton Baker's "Illustrations of Conifers" are now collectors' pieces; but this book continues and modernizes the tradition. Apart from some pages of script, it is essentially a collection of 136 photographic reproductions of the branchlets from sixty-four different conifers. Except in three cases, each species is represented by a photograph, natural size, of the upper and lower aspects of typical branchlets, followed by one at an eight-fold magnification of smaller suitable zones. It is this latter development, the application of pocket-lens photography to conifer branchlets on an extensive scale, which is new and which is the real value of the book because it has been really well done. Mr. B. A. Jay, being an associate of the Royal Photographic Society, is not a tyro in photography, and he has certainly shown his paces in these records. The typical vegetative features used in identification are all here, perfectly and critically displayed, just as they would appear in strong light under a good hand-lens. To the beginner, examining certain conifers for the first time, these photographs must be an inestimable boon; to the older hand their beauty and clarity yield an unfailing pleasure. If one comments that the reproduction in an occasional plate is not perfect, or that, for example, the two characteristic horny points on the leaf of *Abies firma* might be more distinct, it is because most of the others are so good that one wonders at even such small occasional departures from perfection. Perhaps in his next volume of studies Mr. Jay may be induced to give his photographer readers some details of the technique which has proved so successful in his hands.

The set of photographs illustrating each species is very usefully accompanied by a precise diagnostic description which seems accurate in every case. Introductory to the plates is the separate script giving a key to the genera illustrated, specific keys for those genera such as *Pinus* and *Abies* in which a number of species appear, and a useful table giving for each species brief data on nomenclature, occurrence in Britain and sylvicultural importance. A few flaws were noticed in this script. *Pinus coulteri* appears in the diagnostic key (p. 19) to the species of *Pinus* but nowhere else. *Abies procera* is *Abies nobilis* (p. 27) in the key for *Abies*. *Cryptomeria* and *Sequoia wellingtonia* are both said on p. 15 to bear scale-like leaves similar to those of *Cupressus* and then, in the key to the genera, *Cryptomeria* is separated on the basis of having awl-shaped leaves. The leaves of *Sequoia wellingtonia*, described as scale-like in the key to the genera, are referred to in the description under its plate as awl-shaped. This is a little confusing, especially as the foliage of neither can really be considered cupressoid. On p. 10 *Sequoia sempervirens*, obviously accidentally, is bracketed with *Metasequoia* as having linear leaves opposite or decussate. These, and a few other such points, can of course be readily corrected in subsequent issues, if only by an erratum slip. I regret, however, that there is little in the notes on classification on pp. 16–17 with which I can agree, though I am glad to record that Mr. Jay is not responsible for these pages. The nomenclature used follows the 1949 edition of Dallimore and Jackson's "Handbook". It is pleasant, therefore, to see that here, too, the Sierra redwood is still *Sequoia* and not segregated to the indefensible *Sequoiadendron*, though perhaps not everyone will be happy about the specific name now standard and, apparently, necessarily standard.

But the scope of the book must always be remembered in spite of its many excellences. It only deals with sixty-four conifers, and this deliberate limitation definitely lessens its general range of usefulness. Without question, in an arboretum containing only these sixty-four the veriest novice could with certainty identify each. The beginner, however, meeting types outside the selected sixty-four, would soon find himself at a loss because the diagnostic keys given are only valid for the conifers actually illustrated. Even then the selection seems a little unbalanced. The common ones are here and also those of importance in afforestation schemes as well as some of the less common ornamental forms. But surely there are many conifers more commonly to be met with in Britain and thus more deserving of inclusion in this introductory volume than, say, *Agathis australis* or *Pinus cembroides* var. *monophylla* or even *Abies koreana*? However, this criticism only applies to about eight of the forms included.

The book, therefore, must be taken for what it is—a really valuable and instructive collection of photographs of branchlets of a number of selected conifers, mostly fairly common. The excellence of the photographs, especially those at the pocket-lens level, induces one to hope that Mr. Jay will continue to apply his fine skill along the same lines to give us in the near future companion volumes to illustrate those many other interesting conifers which, even if not common, are at least frequent or occasional in Britain.

# GARDEN FLORA OF HARDY PLANTS IN FRANCE

## Flore Illustrée des Jardins et des Parcs

Arbres, arbustes et fleurs de pleine terre. Par Dr. P. Fournier. (Encyclopédie biologique, 38, 39, 40.) Tome 1: Fougères, gymnospermes et monocotylédones. Pp. 340. Tome 2: Dicotylédones. Pp. 552. Atlas. 182 plates. (Paris: Paul Lechevalier, 1951–1952.) 3 vols., 11,000 francs.

MANY of those who are interested in practical horticulture would wish for a not too bulky work that will enable them to identify the plants that are commonly grown in their gardens. The work under review furnishes a key for the identification of the families, the genera and some 6,730 species of trees, shrubs and herbs that are grown in the open air in France. A volume of plates provides line-drawings of details of more than two thousand species to illustrate the text. The value of such a key can only be assessed by its extended use, especially by those who do not already know too many of the answers; but it is obvious that, for a large number of gardeners, this will fill a very real need and should often enable the horticulturist to name his plant with a minimum of trouble. However, as in most such aids to rapid identification, the fact that flowers and fruits are too often not simultaneously available is sometimes forgotten.

Naturally, in southern France plants can be grown in the open that would not be hardy in Britain, so that the inclusion of six species of fuchsia, of several epiphytic orchids or of forty-five different kinds of palm, compared with the single species which is hardy in Britain, causes no surprise. To the British reader, however, the important question is to what extent those species which are hardy in his country are cultivated in France. In the recently published "Gardeners' Dictionary" more than eighty species of *Dianthus* are listed as hardy in Britain, and, of these, twenty-eight are included in the work under notice; of *Cornus*, the French book includes eighteen of the twenty-nine cultivated in the British Isles. So it will be appreciated that a considerable degree of selection has been exercised, and many of the less commonly cultivated species have been omitted. Clearly the author, faced with the choice between the production of a work that would be comprehensive and unwieldy or one that would be relatively convenient to handle but restricted in its scope, has chosen, perhaps wisely, the latter.

It should be added that the illustrative drawings, though often diagrammatic in presentation, are quite adequate for their purpose as aids to identification.

Issued in paper covers at the equivalent of about £11, which presumably includes the third volume of text not yet available, it is to be feared that there will be comparatively few horticulturists outside France who will see their way to buying for themselves a work of this character. E. J. SALISBURY

# POPULATION CHANGES IN EUROPE SINCE 1939

### Population Changes in Europe since 1939

A Study of Population Changes in Europe during and since World War II as shown by the Balance Sheets of Twenty-four European Countries. By Gregory (Grzegorz) Frumkin. Pp. 191. (London: George Allen and Unwin, Ltd., 1951.) 30*s*. net.

SHORTLY after the end of the Second World War the United Nations Economic Commission for Europe began a survey of European man-power. Yet the present cannot be understood without a knowledge of the past, and it quickly became clear that the demographic upheaval caused by the War was largely uncharted and very ill-recorded. M. Gregory Frumkin, formerly editor of the "Statistical Yearbook of the League of Nations" and now a member of the United Nations Secretariat, undertook the heavy task of piecing together the demographic history of Europe for the War period. The result is a scholarly compilation of the main changes in total population of twenty-four European countries for the two periods end-1938 to end-1945, and the succeeding years 1946–47. The U.S.S.R. is excluded from the main account because accurate data are non-existent.

A valuable feature of the work is the author's insistence on a standard treatment for every country. National statistics, based on a variety of definitions and relating to a multiplicity of dates, have been rearranged to conform to a standard pattern. This commendable attack on the difficult problem of international comparability inevitably results in estimation and its attendant errors. Yet these will be of small account compared with the uncertainty which still surrounds the extent of the loss of human life from genocide, and the size of the migratory movements, voluntary and involuntary, which swept across Europe in the wake of the Nazi terror.

M. Frumkin insists on independent estimates of all components of population change. These are: births, deaths (divided into those directly attributable to military operations, mass murders and 'normal' deaths), losses and gains from territorial changes, and the successive waves of migration during and after the War. Official statistics, amended to fit the author's standard form, provide starting and finishing check-points. If the account for any country does not balance, and it rarely did, then one at least of the estimates must be wrong. The major part of the author's research has been the patient examination and reconciliation of the many discrepancies he uncovered. He has avoided residual or balancing items which merely reflect an accumulation of errors in the remaining figures.

The general approach is described in Chapter 2. The next chapter is the core of the work and contains a survey of population changes for each country separately. The whole account is preceded by a brief description of the characteristics of population growth during the 1930's, and concluded by a summary of the changes wrought by the War. One of the more horrifying tendencies of modern warfare is laid bare: "Out of 10 million war losses in countries under Nazi control . . . 8·6 millions related to losses among the civilian population and only 1·4 million were military losses". Not least in interest is the evidence of the remarkable recuperative power of a population. By the end of 1947 the total population of the countries surveyed had overtaken war losses and exceeded the total at the end of 1938 by some four millions.

H. SILCOCK

# LIPID METABOLISM

### Biochemical Society Symposia

No. 9: Lipid Metabolism, a Symposium held at the London School of Hygiene and Tropical Medicine on 16 February 1952. Organized and edited by R. T. Williams. Pp. v+102. (Cambridge: At the University Press, 1952.) 13*s*. net.

THIS volume contains the papers communicated in substance to the Biochemical Society's symposium on February 16, 1952 (see *Nature*, 169, 569; 1952). The publication in full of the memoirs then dealt with is welcome, since in each instance a fairly full survey is presented which offers a more-or-less complete picture of each subject considered. The collection, which has been prepared by Prof. R. T. Williams and published for the Biochemical Society in the clear and excellent format common to all the Society's publications, is therefore of value to both students and investigators who are concerned with the problems discussed at the symposium.

The first three communications (by Prof. A. C. Frazer, Dr. R. P. Cook and Dr. J. M. French) deal with the absorption of fat by animals. Prof. Frazer's review of the work of his own school and of others during the past thirteen years on the mechanism of fat absorption gives a picture of the conclusions reached up to the present time. It suggests that the balance of evidence is in favour of his partition hypothesis, which presupposes only partial hydrolysis of ingested glycerides with intraluminar emulsification of glycerides as an important step in their absorption; and that the alternative view of complete hydrolysis of glycerides to fatty acid and glycerol, followed by re-synthesis in the intestinal cell to phospholipids (as an essential intermediate), is no longer tenable.

The contributions of Dr. G. Popják and Dr. S. J. Folley on the synthesis of fatty acids in animals, especially in their mammary glands, from acetate (or from glucose via acetate or pyruvate) will receive much notice, since the recent important studies of both authors in this field are collected and discussed in relation to results obtained by other workers. It is of great advantage to have the results which have been disseminated in a large number of individual papers in the scientific journals brought together by two of the most prominent investigators of this subject. Dr. Popják's review concerns the evidence, based on work with radioactive acetate, of synthesis of fats in general from small (two-carbon) molecules, while Dr. Folley's is more specifically devoted to the biosynthesis of milk fat in ruminant mammals. The two articles together give a complete account of the subject as it stands at present.

Dr. A. L. Lehninger gives in some detail an account of recent work by himself and his colleagues on the mechanism of the enzymatic oxidation of fatty acids. The discussion includes sections on the properties of the fatty-acid oxidase system of animal tissues, on the mechanism of acetoacetate formation and oxidation, and on the significance of recent work on fatty-acid oxidation and synthesis in extracts of *Clostridium kluyveri*.

The final paper, by Dr. H. M. Sinclair, deals with the fatty acids (linoleic, linolenic, arachidonic) essential to growth and their relation to pyridoxine. This very interesting contribution, which merits careful study, brings out an analogy between deficiency of essential fatty acids and deficiency of pyridoxine. It is suggested that failure of growth in essential fatty-acid deficiency may be connected with inability to form the phospholipids necessary for cell membranes, and also that the essential poly-unsaturated acids may be concerned in controlling the water retention of animal tissues.

It is to be hoped that this, necessarily brief, notice of the contents of the volume may serve to indicate its usefulness to all interested in the role of lipids in biochemical processes.

## COSMIC RAYS AND THE CLOUD CHAMBER

### Cloud Chamber Photographs of the Cosmic Radiation

By G. D. Rochester and J. G. Wilson. Pp. viii+128. (London: Pergamon Press, Ltd., 1952.) 70*s*.

THE authors of this book, Dr. G. D. Rochester and Prof. J. G. Wilson, are to be congratulated on its production; in bringing together in one volume a very fine collection of photographs, they have paid worthy tribute to the part the cloud chamber has played in revealing the nature and associated properties of the fundamental particles which are found in the cosmic radiation. To each photograph (the total number of which is one hundred and twenty-three) the authors have prepared a most useful synopsis giving not only the details of the actual chamber and the geometry of the accessory equipment such as position and size of lead plates, but also an analysis of the physics of the event in question; this includes both the results of the measurements made upon the tracks and a discussion of the resulting interpretation of the event. It cannot be stressed too strongly that all nuclear physicists will benefit from a study of the photographs whether or not they are versed in the technique of the use of expansion chambers. It is true that to those who are so versed the book will be of extra value in that it shows the results obtained from chambers covering a great range of sizes, operating pressures, etc.; but the outstanding merit of the book is the fact that it describes and discusses, in an interesting manner, real fundamental physics. The quality of the reproduction of the photographs is excellent and is immediately impressive.

The photographs are grouped in six sections. Section 1 is entitled "Technical Features of Operation" and illustrates the process of formation of drops, the efficiency of condensation upon ions, the effects of turbulence and contamination within a chamber, and other features. Section 2 deals with electrons and cascade showers, and the first few plates show the tracks which revealed the existence of the positron and the cascade process; photographs of extensive showers show not only the presence of cascade particles, but also penetrating particles together with nuclear interactions associated with such showers. Section 3 is concerned with the existence and subsequent decay of the $\mu$-meson; a most important group of photographs demonstrates the way in which the mass of a particle may be determined from momentum and range measurements, and includes an indication of the nature and magnitude of the uncertainties involved.

Nuclear disintegrations and interactions of secondary particles form Section 4, which covers reactions observed in multi-plate chambers (for example, of carbon and lead), as well as stars produced in the gas of the chamber.

The photographs which have made it necessary to postulate the existence of charged and uncharged *V*-particles are shown in Section 5. The interpretation of these photographs is clearly discussed and well illustrates the vital contribution to physics which may be contained in only a few photographs. Section 6 consists of a single photograph showing the track of a primary cosmic-ray particle in a chamber operated at an altitude of 95,000 ft.; this photograph is indeed a tribute to the skill and ingenuity of the research worker, as well as the reliability of the expansion chamber.

It is to be hoped that the authors intend to keep the material of the book up to date either by appropriate revision or by the publication of a second volume when sufficient progress has been made. On this assumption, a few minor suggestions may be offered. In the technical descriptions of the chambers, more details of the magnets, lamps, cameras and general illumination geometry would be useful. In the case of experiments where the counter selection is complicated, a simple schematic diagram would be valuable; in the first section dealing with technical operation of chambers, more 'faults' should be included showing the different effects of intrinsic chamber faults (for example, inadequate temperature control), control faults, and illumination and/or recording faults.

The price of the present volume is rather high, but it must be appreciated that, where it is required to have an overall reproduction of such a high standard, a high cost is unavoidable. J. R. Atkinson

## Management and Conservation of Vegetation in Africa

A Symposium. (Commonwealth Bureau of Pastures and Field Crops, Bulletin No. 41.) Pp. 97+14 plates. (Farnham Royal: Commonwealth Agricultural Bureaux, 1951.) 10*s.* 6*d.*

THE title of the symposium which this book records is perhaps liable to lead to unfulfilled expectations. There is relatively little emphasis on management and a lack of data on conservation. The emphasis is rather on the need for vegetation surveys, which, however desirable in themselves, as a record of what now exists, can alone do little, if anything, to arrest the losses we all deplore. One of the great needs in Africa concerns the controversy that still rages as to whether to burn or not to burn, and I recently heard in South Africa both views defended with great vigour. Even where there is a measure of agreement that some burning is desirable, or at least unavoidable, there are few precise data as to when and how often to burn so as to attain the optimum result.

The first of the contributions included in this volume is by J. P. Scott, who does in effect consider, all too briefly, the actual principles involved in conservation. G. C. Edwards, writing on the vegetation types of East Africa, stresses the need for a changed system of agriculture based upon the ecological conditions, of which the native vegetation is the best indication, and he advocates the value of a temporary ley as the best means of building up and conserving soil fertility. H. J. Rensberg strikes a similar note for the Tanganyika area. An interesting account of the ecology of savanna in Nigeria is provided by R. N. J. Keay, while A. Fogie gives a summary of the forest reservation in the Gold Coast. There are also brief accounts of what is being attempted in the Sudan and Sierra Leone.

With such a title, however, one might have anticipated some account of the experimental results achieved in various areas, such as those carried out at the experimental station at Frankenwald. Nevertheless, with all its limitations, this is a book that all those interested in such problems will find of value.

E. J. SALISBURY

## Statistical Methodology Reviews, 1941–1950

Edited by Oscar Krisen Buros. Pp. xi+457. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1951.) 56*s.* net.

THIS is the third compilation issued by Prof. O. K. Buros, the last being published in 1941. It assembles in one large well-printed volume the reviews of books on statistical methodology published in English during the decade 1941–50 and contains 842 review excerpts from 112 journals covering 342 books. There are, in addition, useful indexes of periodicals, publishers, titles and authors' names, as well as a classified index to the books themselves.

A would-be student of statistical methods will find it useful to consult this work to see what books have been published and what reviewers think about them. But for statisticians and reviewers of any class of scientific book the work will have a wider appeal, not to say a considerable entertainment value. It is a fascinating study to compare a number of reviews of the same work and to observe the variation of opinion expressed in them. Review editors will also find much here of help in framing their general policy. One of Prof. Buros's objects in embarking on this work some fifteen years ago was to improve the quality of reviews, and a comparison of this book with its predecessor, the "Second Yearbook", indicates that he has been partly successful. It is to be hoped that he will continue to find support for this useful enterprise.

## Understanding Heredity

An Introduction to Genetics. By Richard B. Goldschmidt. Pp. ix+228. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1952.) 30*s.* net.

THIS book is intended for the educated layman who wishes to acquire an elementary knowledge of genetics. Its aims are to give a broad outline of the subject and of its implications in biology and in everyday life, and to stimulate enough interest to make the reader eager to attack some more advanced treatise. There is no denying that to many it will come somewhat as a disappointment. From Prof. R. B. Goldschmidt, who has been constantly and successfully ahead of the times in criticizing the shortcomings of accepted genetical concepts, one would have expected better. The very necessary sacrifices required by simplification and conciseness do not justify the omission of the salt and pepper, that is, the problems still unsolved and the wider vistas opened up. As an addition to the number of books giving in a simplified form the main facts and ideas of genetics, it will have its value.

G. PONTECORVO

## Substances naturelles de synthèse

Préparations et méthodes de laboratoire. Collection publiée sous la direction de Dr. Léon Velluz. Vol. 4. Pp. 165. (Paris: Masson et Cie., 1952.) 1800 francs.

VOL. 4 of this series follows the same plan as the earlier volumes (see *Nature*, 169, 169; 1952). The more important and larger part of the book gives experimental details, taken from recent chemical literature, for the laboratory preparation of certain biologically important substances.

The preparations described are *d*-pantothenic acid (Stiller, Harris, Finkelstein, Keresztesy, and Folkers, *J. Amer. Chem. Soc.*, 1940), adermine (Harris, Stiller, and Folkers, *J. Amer. Chem. Soc.*, 1939), riboflavine (Karrer and Meerwein, *Helv. Chim. Acta*, 1936), testosterone (Serini and Köster, *Ber.*, 1938), and *dl*-$\alpha$-tocopherol (Smith and Sprung, *J. Amer. Chem. Soc.*, 1943). Each synthesis is prefaced by a short introduction and is followed by a lengthy series of notes on related processes, etc.—for example, analogues of pantothenic acid, $\beta$-alanine, the phthalimide synthesis, elimination of hydroxyl from aromatic heterocyclic compounds, ethoxyacetylacetone, 3 : 4-xylidene, amino-saccharides, etc. In several cases, alternative syntheses are discussed.

The second half of the book contains lengthy sections on cyclizations leading to derivatives of pyridine and on adsorption chromatography, including practical notes on the preparation of adsorbents. There are finally some tables relating metric to other measurements, °F. to °C., and lb./sq. in. to kgm./sq. cm. The price of the book is very high considering that all the factual information is readily available elsewhere. If many of the notes and addenda were omitted, these volumes would lose little of importance and could be published at a lower price.

W. BAKER

# UPWELLING IN THE BENGUELA CURRENT

By RONALD CURRIE
National Institute of Oceanography

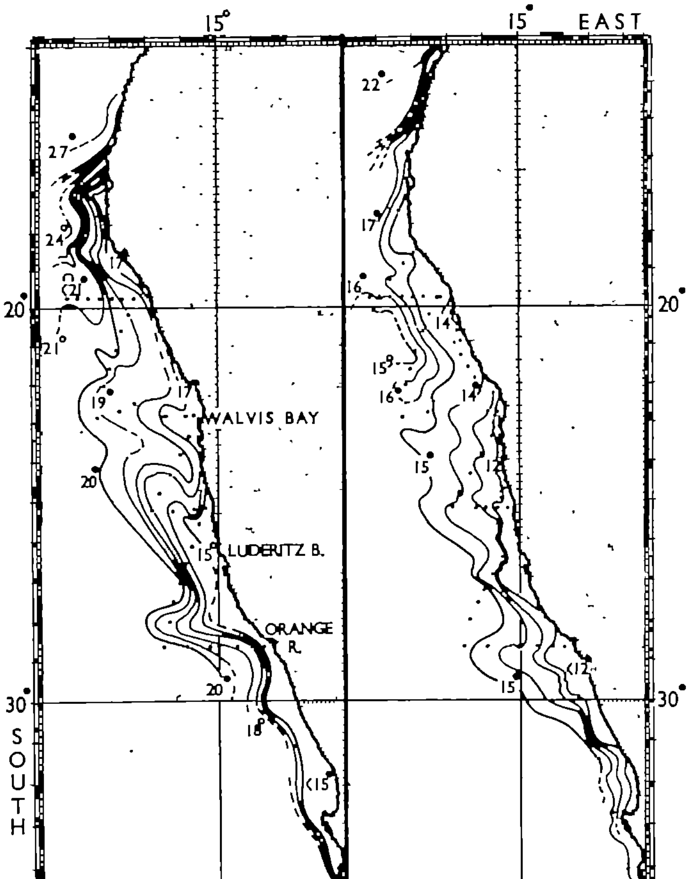
THE Benguela Current is one of the major features of the circulation of the South Atlantic Ocean. Extending northwards along the African coast from the neighbourhood of Cape Town to about lat. 15° S., the current is a region of upwelling of relatively cold water rich in nutrient. The resultant high fertility of the surface waters gives rise to great production of planktonic plants and animals, while the presence of the cool water has extensive climatic effects. In such features the Benguela Current has much in common with the Peru Current, which was surveyed by the R.R.S. *William Scoresby* under the Discovery Committee in 1931. When this ship visited South African waters in 1950, two surveys of the Benguela Current were carried out, first in March and again in September–October. The programme for the voyage was planned by Dr. N. A. Mackintosh, and it included these surveys not only to allow a comparison to be made with conditions in the Peru Current but also because such regions are specially favourable to investigations on the production of life in the sea.

The German Atlantic Expedition (in the *Meteor*) was the first to study the current extensively, and it enabled Defant[1] to produce the most comprehensive account of it so far. The *Meteor* observations, however, were relatively widely scattered in space and time; they provide a broad picture of the current and its effects in relation to the South Atlantic as a whole, but leave much to be learnt of the fluctuations of the current and the mechanism of upwelling. Hence the *William Scoresby*'s work included lines of closely spaced 'stations' off the South West African coast (Fig. 1). Limited time restricted them to the coastal region, but these intensive observations covered the area which, in view of Defant's findings, was most likely to be of interest.

As the surface currents of the eastern side of the South Atlantic are principally wind-driven systems, to understand them one must have a knowledge of the prevailing winds. Over the South Atlantic the surface winds blow out anticyclonically from a large region of persistent high pressure, and the component blowing over the eastern part of the ocean is the South-East Trade Wind. Near land, however, the trade wind develops a landward component which varies with the fluctuations of pressure over the continent, this in turn resulting from the great heating and cooling which the land mass undergoes. This landward wind or sea breeze thus shows a marked diurnal variation, and frequently attains considerable force, blowing from almost due south in lat. 30° S., and veering to south-west northwards along the coast.

It is not surprising, therefore, that the sea surface currents should show considerable irregularity in the coastal region. Defant, from an analysis of the Dutch current observations, found that inside the relatively constant drift current produced by the South-East Trade, the coastal currents were extremely irregular, and were separated from the drift current by a "one-sided line of divergence". Further, Defant showed that the region of strong negative temperature anomaly was confined to the coastal current.

*Distribution of temperature and salinity.* The accompanying charts (Fig. 1) show the distribution of surface temperature, compiled from the 'station' observations and supplemented by the data from a distant-reading thermograph with which the ship was equipped. On both surveys, the most outstanding feature of the distribution was the pronounced irregularity of the isotherms. Whereas the isotherms of the open ocean run more or less latitudinally, in the



(a) (b)

Fig. 1. Sea surface isotherms (a) during March, (b) during September–October 1950. Isotherms are drawn for each whole degree C. Stations are shown by dots

Benguela Current they run approximately parallel to the coast. The existence of the interlocking tongues of relatively cool and warm water suggests that the upwelling of cool water to the surface occurs not everywhere, but at separated points along the coast. The distribution of salinity follows a pattern similar to that of temperature, the lower salinities occurring in the cool water against the coast. Offshore, one finds that, while the temperature rises relatively steadily, there is a sharp contrast between the salinity of the inshore waters (c. 35·00‰ or less) and that of the offshore waters (c. 35·20‰). It appears, therefore, that there are two distinct surface waters, generally with a fairly sharp boundary between them, although in places mixtures occur. The inshore water generally has similar properties to the water at subsurface depths farther offshore.

Examination of the vertical distributions of temperature and salinity shows that on both surveys a well-developed homogeneous surface layer was present offshore. This was separated from the underlying water layers by a strong temperature discontinuity. Inshore, however, there was evidence of considerable variation: during the first survey no such homogeneous layer was detected, and strong heating had apparently taken place on the surface; but during the second survey, there was a thin homogeneous surface layer overlying a weak discontinuity. This difference indicates the contrasting effects of the calm conditions during March and the strong winds during September–October.

Below the upper water layers, both temperature and salinity fell steadily to the salinity minimum of the Antarctic Intermediate Current. Fig. 2 shows the dispersion of all the temperature and salinity observations made in 1950 by the *William Scoresby*, between a depth of 100 metres and the Antarctic intermediate salinity minimum. It can be seen that all lie within narrow limits of the characteristic temperature – salinity curve of the South Atlantic Central Water[2]. As the Antarctic Intermediate Water moves north, it mixes vertically with the overlying and underlying more saline waters. Consequently, the salinity minimum becomes less pronounced towards the north until, finally, it becomes obliterated completely. Using Wüst's 'Kernschichte Methode'[3] —the heavy line in Fig. 2—one finds that in the core of the Antarctic Intermediate layer off South-West Africa only 50 per cent of the original water type remains and this at a depth of more than 600 metres. Since our data indicate that the upwelling does not extend much below 300 metres, it is only a relatively small proportion of Antarctic intermediate water which is subject to upwelling.

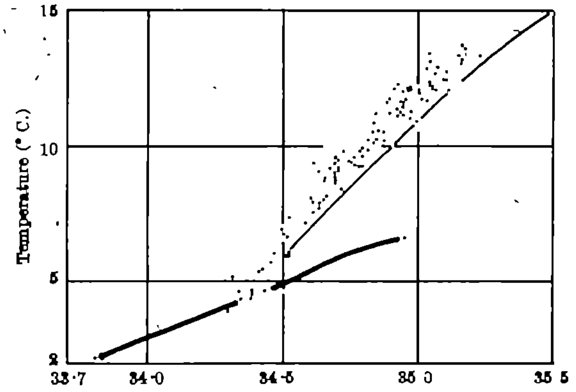


Fig. 2. Temperature – salinity relationships of the water layers between 100 metres and the salinity minimum of the Antarctic Intermediate Water. The heavy line shows the relationship of the core of the Antarctic Intermediate Water from the source (left) to the northern limit (right) after Wust (ref. 3). The thin line is the line characteristic of South Atlantic Central Water (Sverdrup, ref. 2)

The strong indications of active offshore transport of surface water during September–October, compared with the more quiescent conditions found in March, demonstrate the difference between active upwelling and the more advanced stage of mixing of previously upwelled water. The dynamical principles of the movement of a northward-flowing current in the southern hemisphere require that the more dense water should lie in the east side of the current, and upwelling may purely be a lifting effect within the current.

The wind records for the periods preceding the two surveys leave no doubt, however, that the great difference between the surveys was a direct result of the prevailing wind conditions. No detailed observations of the wind over the sea are available; but it is known that the trade winds were much stronger during September–October than during March. In addition, wind records from three South-West African shore stations show that whereas the sea-breeze was light and variable during February and March, it would have been conducive to a longshore transport of surface water during September–October.

Since there are no direct observations of current, the anomalies of dynamic depth of the isobaric surfaces have been calculated, with reference to the 600-decibar surface. Although in a region where vertical movements are important this method must be used with much caution, the inferences appear reasonable, and show similar features to findings in other regions[4,5]. During March, the computed currents show a general movement to the north with a rather weak southerly movement inshore, reaching to about Luderitz Bay. During September October, a series of horizontal eddies was present inside a much stronger northerly flow. Vertical sections through the eddies indicate that the sea surface slopes upward from the coast to a line of convergence, and then falls into a trough, and farther offshore slopes upwards again. On some of the sections the observations did not extend far enough seawards to show this trough, although the line of convergence was always well marked. Since the sea surface must eventually rise towards the open ocean, however, it is probable that such a trough was there. An example of this distribution is given in Fig. 3. Sverdrup[4] has pointed out that in a region such as this (Sverdrup deals with the Californian coast), strong convection will develop between the more dense water upwelling and being transported offshore and the light offshore water, sufficiently well defined to be regarded as a boundary. Seawards of this boundary there is a tendency for divergence within the offshore water due to the increasing effect of the wind on the surface. A circulation of two vertical cells would thus be formed, separated by a strong convection current. As the boundary moves offshore, there must be a compensation flow into the inner cell, and this Sverdrup defines as the upwelling movement, the upward movement above being part of the cellular circulation. Superimposed upon this vertical circulation must be a horizontal eddy formation.

It appears, therefore, that the circulation is somewhat more complex than Defant could deduce from the data at his disposal, and the 'one-sided divergence'

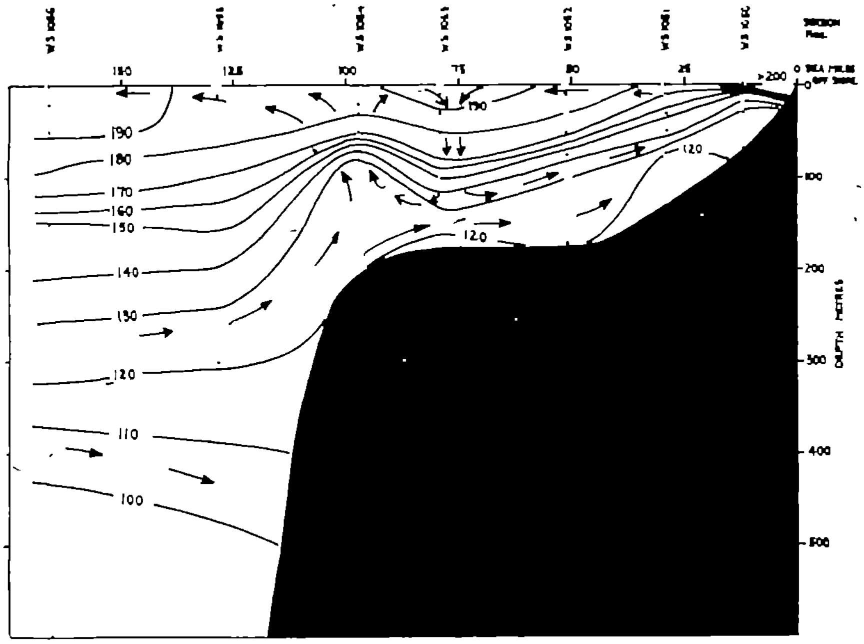

Fig. 3. Vertical section normal to coast in lat. 23° 40′ S. showing isosteres and probable direction of water movement in the vertical plane. (Isosteres are the lines of equal specific volume expressed as the difference × $10^5$ from the specific volume of sea water of 35 parts per 1,000 salinity and 0° C. at the same pressure)

seems to be an eddy-like system rather than one long continuous divergence line. The size and stability of these eddies must depend upon the intensity of the forces which produce the upwelling, and about which there is still little precise information. The distance to which they persist must be variable and governed by the variability of the external forces. Whether the eddies are consistently formed in any particular regions is difficult to say without more intensive observations, although the continuous low temperatures and high productivity of the region around Luderitz Bay (c. lat. 26° S.) suggest that this may be one region where eddies often form.

Although no significant temperature – salinity differences occur in the underlying water layers (Fig. 2), there is a great depletion of dissolved oxygen and enrichment of phosphate close to the continental slope. This layer of oxygen minimum and phosphate maximum is similar to that found extensively over the equatorial regions of the ocean. It probably results from a balance between the rates of decomposition of organic matter, and the turbidity and diffusion rates between those layers and the neighbouring water masses. Upwelling brings some of this poorly oxygenated, highly nutrient water into the euphotic zone. Although this will favour great phytoplankton production in the surface layer, the low oxygen content will help the effects of local decomposition of organic matter to maintain almost anaerobic conditions in the shallow reaches of the continental shelf.

The inorganic phosphate content of the upwelled water is very high (> 2·0 mgm. atoms phosphorus/$m.^3$, about four or five times the present normal winter maximum of the English Channel[6]), in contrast to the almost complete absence of phosphate in the offshore surface waters. Local maxima and minima occur, as the oxygen shows varying degrees of saturation with the varying abundance of the phytoplankton populations. It was found that the phosphate content on the shelf was often greater than that in the upwelling water. This may be due to intense local regeneration from decaying plankton.

During the second survey an attempt was made to measure the extent of the 'azoic zone', a region of reducing mud[7], and this was found to cover a larger area than was previously supposed. A series of Baillie rod soundings revealed that it extended, at least in patches, between depths of 50 and 150 metres, for about 400 miles north of lat. 25° S. The sediment, a dark green diatom mud, is populated with sulphate-reducing bacteria; their production of hydrogen sulphide must further reduce the oxygen content of the local shelf waters. The oxygen depletion was most marked near Walvis Bay: during March the water with less than 1·0 c.c. oxygen per litre extended to the sea surface; during September–October, however, these low concentrations were confined to the lower third of the water column. In the determination of the oxygen, steps were taken to eliminate the effect of large quantities of reducing substances and organic matter.

At times, the concentration of hydrogen sulphide becomes so high that the gas is actively evolved from the sea surface. As this frequently occurs at the same time as mass mortalities of marine organisms, some authorities have attributed the mortality primarily to an oxygen deficiency. Brongersma-Sanders[8] has, however, preferred to consider the effects of toxins released from mass outbursts of certain dinoflagellates as being the primary cause, principally on evidence from other similar regions.

Dr. T. J. Hart has found 3,000–5,000 cells/ml. of small dinoflagellates in samples collected from discoloured water patches during these surveys. They have not been finally identified, but probably belong to one of the several genera known to include species capable of producing toxic effects. Small mortalities actually occurred during March 1950, but there is insufficient evidence to show which factor was the more important. The effect may well be due to several unfavourable factors acting together.

A paper on preliminary results of analyses of the other plankton samples by Dr. Hart will appear shortly. This shows that good agreement between the plant and animal distributions and the physical and chemical data is often apparent. Thus all the very heavy diatom populations occurred in the upwelled water; and they coincided with the highest supersaturation values of the surface water with oxygen. At times, dense concentrations of Chætocerids imparted an olivaceous colour to the upwelled water, in contrast to the transparent blue offshore water. The scanty phytoplankton of the latter included a relatively high proportion of the diatom *Planktoniella sol*, which seems a useful indicator of intrusions of offshore water towards the coast, as

Gunther and Rayner[9] had found previously, off Peru.

The physical and chemical results will be published shortly by the National Institute of Oceanography in the 'Discovery' Reports, and further studies are being made of some of the problems which have been mentioned with the particular object of obtaining evidence about the factors which affect oceanic productivity.

# MAGNETIC PROPERTIES OF ROCKS

THE significance of the natural-remanent magnetism of igneous and sedimentary rocks has not yet been determined. On one hand, there is the hypothesis that the direction of magnetization can be interpreted in terms of a widely varying magnetic field and, on the other, that the adverse polarizations arise from intrinsic properties of the rock assemblage. These aspects formed the main theme of a geophysical discussion at a joint meeting of the Royal Astronomical Society and the Geological Society, held in London on January 23, with Prof. E. C. Tilley (Department of Mineralogy and Petrology, Cambridge) in the chair. Prof. Tilley noted that the magnetic properties of rocks have also been found to be of considerable value to geologists by yielding magnetic anomalies reflecting the distribution of certain rock-types, the measurement of such anomalies culminating in aeromagnetic surveys.

In opening the discussion, Dr. J. M. Bruckshaw stated that the value to the geologist of the results he proposed to discuss would be controlled by their final interpretation. Of recent years the study of permanent rock magnetism has been intensified, and Dr. Bruckshaw's interest was first aroused by the discovery that the tholeiite dykes of northern England are magnetized in a direction opposite to that of the present earth's field. Since these dykes represent the final phase of igneous activity centred upon Mull, it was an obvious step to examine the rocks in the earlier phases of this activity. The earliest phase was the quiet extrusion of a sequence of lava flows followed by the cyclic intrusion of basic and acid ring dykes and cone sheets about a centre which migrated twice towards the north-west. The final phase was the production of the north-west dyke swarms, of which the tholeiite dykes were the last members. Since a known time-sequence of events exists, it is possible to sample rocks of different periods and, in the present case, some of the basalt flows, some early basic intrusions, the ring dykes of Glen More and Loch Bà and some of the north-west dykes were examined. After a rock has been polarized, many factors may tend to modify it, and some influences will result in random magnetization. For example, a partially solidified lava-flow might be broken up by a further supply of lava. Thus a number of specimens from each formation must be examined, and they usually show a scatter of directions. Inspection may be sufficient in some cases to determine if the mean direction has a significance, but the probability that the observed set of directions can be selected from a random distribution is used for indicating what weight can be attached to the mean direction; the smaller the probability the more significant the mean direction.

Using those formations associated with significant directions, the basalt flows proved to be adversely magnetized and also the early basic intrusions. The more acid ring dykes of Glen More and those of Loch Bà were normally magnetized; but a dolerite dyke, earlier than the Loch Bà granophyre, proved adversely magnetized. The dykes of the north-west swarm were normal, and to this must be added the adverse phase of the tholeiite dykes, giving a total of three adverse phases.

The large observed intensities of magnetization in relation to the earth's magnetizing field can only be explained in terms of thermoremanence acquired during the initial cooling, the only occasion when the present rocks were at the necessary high temperature. If this is accepted, the amazing stability of this polarization follows; and laboratory observations support this conclusion, the coercive force of the rocks being comparable with that of modern magnet-steels. In all respects the rocks exhibited ordinary magnetic properties under a variety of conditions and, in particular, acquired normal polarization when cooled in the earth's field. It would thus appear that the simplest explanation of the facts is a number of reversals of the earth's magnetic field in the past, a suggestion to which there are no theoretical objections.

Mr. K. M. Creer pointed out that the main evidence on adverse magnetization comes from igneous rocks, which are magnetized either normally or at 180° to the normal direction. Although there are no theoretical objections to a reversal of the earth's polarity, other explanations of adverse magnetism are possible, such as those suggested by Néel. One of these assumes a constituent having a spinel structure in which two sub-lattices exist, one tetrahedral and the other octahedral. The spontaneous magnetic vectors associated with the sub-lattices have opposite directions and, in suitable conditions, the resultant magnetization would change sign with temperature, thus allowing adverse polarity. This property of imperfect antiferromagnetism is not known. Another process involves two magnetic constituents with widely differing Curie temperatures. On cooling, the constituent of higher Curie point is first magnetized and produces a demagnetizing field. Due to its large negative temperature-coefficient, the initial intensity grows rapidly and the demagnetizing field ultimately exceeds the original field at the Curie point of the second constituent, which becomes adversely magnetized. The ferromagnetic constituents must occur in aggregates of high local concentration.

Mr. Creer recorded that a hypersthene hornblende dacite discovered by Nagata does exhibit adverse magnetization when cooled in a weak field. From it, two magnetic constituents have been separated by Dr. G. D. Nicholls, of the University of Manchester. One (probably magnetite) behaves normally, but the other shows reversed thermoremanent magnetism. He suggested that the normal behaviour of naturally adversely polarized rocks in the laboratory could be attributed to the rapid rate of cooling, when the components required by Néel do not have time to exolve.

Finally, Mr. Creer considered the evidence of sediments which, on Néel's theory, should not possess inverted magnetism. In the Appalachian Mountains, adversely magnetized Silurian sediments are interbedded with similar but normally magnetized sediments, and these are contemporary, as revealed by the presence in both sets of ostracods of short-time duration, with flat-lying and normally magnetized sediments outside the geosyncline. Thus, any field reversal must have been of a local character, and the reversed sediments in the geosyncline may be the result of a complex history during the mountain-building orogeny. Certain physical differences between the sets of sediments suggest a second interpretation that the polarization of the geosynclinal sediments is stable, but in the flat-lying beds it has, on the whole, followed the subsequent changes in the earth's field. In fact, the absence of any widespread reversals in sediments may be due to instability. Graham's experiments on sediments over a wide time-range show that the most frequent direction of magnetization agrees with a normal dipole field, while conglomerates, which should exhibit random magnetization of the pebbles, show a systematic direction agreeing closely with the present field.

The testing and use of magnetic-survey methods by H.M. Geological Survey and Museum was outlined by Dr. A. F. Hallimond. The problem of the correlation between the observed anomaly and that computed for the structure was initially examined in 1929 by a magnetic survey over the Swynnerton Dyke in Staffordshire; but certain aspects of the interpretation of the field observations proved difficult, since the anomaly due to the splitting of the dyke into two branches gave results similar to that over a dyke with concentrations of magnetite near its flanks. In the simpler cases, however, the observations conformed with theory. Later work over the Lornty Dyke at Bairgowie in Perthshire gave a totally different anomaly from that predicted on the basis of its induced magnetism due to abnormal permanent magnetism. Just before the Second World War, it was demonstrated, in association with Prof. J. T. Whetton, that shallow deposits of weakly magnetic hæmatite could be located by their associated magnetic field. Among others, investigations were carried out over the Brockhill Dyke (Worcestershire) and also in Teesdale over faults in the Whin Sill. The former resulted in the tracing of the extensions of the dyke to the east and west, but estimates of width were rendered difficult because of the appreciable width of the adjoining, and magnetically altered, sediments. Two well-defined faults were followed in the Whin Sill and, in addition, observations over two outcrops, with strikes roughly parallel to and at 45° with the magnetic meridian, permitted the rough resolution of the permanent and induced intensities. The measurements were compatible with an induced polarity based on a susceptibility agreeing with direct observation, together with a horizontal permanent intensity directed approximately due south. The value of magnetic observations as an aid to geological investigations has been fully confirmed by the tests.

Mr. J. Hospers stated that his experiments support the suggestion of a reversed field, rather than that of some property of the rock, to account for adverse magnetism. In Iceland the examination of historical flows between A.D. 1766 and 1948 gives a mean direction of magnetization making an angle of 7° with the present field and 1° with an axial dipole field, and post-glacial flows, between two and six thousand years old, have a mean declination of 1·1° and a dip of 73·8° downwards, very near the dipole field. On the other hand, Early Quaternary flows, of a million years old, have a mean direction making an angle of 8° with the opposite direction of the present field. Below these there is a zone of normally magnetized Tertiary lavas followed by zones of alternate adverse and normal magnetization. The picture revealed is consistent with the idea of a sequence of field changes, occupying about ten thousand years, followed by a period of steady conditions, either normal or adverse, for some half a million years. It was emphasized that, the polarization of sediments between the flows conforms with that of neighbouring flows.

This conclusion is supported by the behaviour in the laboratory of rock specimens when heated and cooled. A rock, possessing adverse magnetization assumed to have been acquired by Néel's two-component mechanism, when heated should show a reduction in intensity as the temperature approaches the lower Curie point of the two constituents and, at some temperature just below this critical point, the reduced adverse polarization should be balanced by the normal polarization of the constituent of high Curie temperature. At the lower transition temperature the normal polarization only would operate, and this would finally fall to zero at the higher Curie point. Thus, the curve of intensity against temperature should show a reversal of polarity, a behaviour which was, in fact, observed for the dacite discovered by Nagata. Both normally and adversely magnetized specimens from Iceland, however, exhibit a monotonic fall to zero with increasing temperature, with no evidence of a reversal. Thus, Néel's two-component mechanism cannot apply. Some curves suggest two similarly magnetized constituents of differing Curie temperatures. On cooling in the laboratory field, each specimen recovers its polarization, the cooling curve matching closely the heating curve, a behaviour consistent with the hypothesis of a field reversal.

Prof. Tilley read a contribution from Prof. A. F. Buddington (Princeton University) in which some extensive negative anomalies, revealed by an aeromagnetic survey of the north-western Adirondacks, were discussed. Specimens of the gneisses, with which these anomalies are associated, possess inverse polarization in all cases, and this appears to be related to the ilmeno-hæmatite or titaniferous hæmatite in the rocks. The literature shows the presence of hæmo-ilmenite, titaniferous maghæmite and other similar minerals in rocks possessing adverse magnetization, and the general conclusion is that these minerals, with abnormal magnetic properties, are responsible for the phenomenon. The fact that magnetite, contemporary with these, often possesses normal polarity adds weight to this conclusion. No inference concerning the earth's magnetic field can thus be made until the possible significance of these minerals has been ascertained, the identification of the minerals requiring X-ray, chemical and microscopic examination.

The general discussion was opened by Sir Lewis Fermor, who described some of his early experiences in the Central Province of India during 1906, following the discovery that certain manganese minerals were magnetic. A dip needle gave very different readings over manganese ores and over the adjoining gneisses and schists. Due to a defect in the instrument, a systematic survey was not made and the observations were not published. Nevertheless, it was of interest to note that the Geological Survey of India had employed successfully the magnetic method in the search for manganese. Referring to the production of adverse magnetization by the processes suggested by Néel, Dr. S. A. Vincenz stated that the first need not be discussed since no such substance is known; but the second process is feasible. The latter is based upon the presence of two constituents, of differing Curie points, and their concentrations in aggregates or "amas". Using the formula developed by Néel and the observed properties of the Mull rocks, the required concentration in the aggregates can be determined. For the lavas and the olivine gabbros, these prove to be 42 per cent and 58 per cent, respectively, and he asked if there is any evidence for a distribution of ferromagnetic minerals in concentrations of this type. Dr. Vincenz also stated that the Swynnerton Dyke possesses remanent magnetism perpendicular to the present field, and similar results have been observed in some Tertiary Welsh dykes. It was pointed out by Dr. H. Manley that only one rock shows adverse magnetism in the laboratory compared with the many hundreds which behave normally.

A remarkable anomaly, associated with a dolerite sill in New South Wales, was described by Mr. A. Day, in which comparable positive and negative centres occur. As titanium is found in the rock, he suggested that a microchemical analysis for titanium in the magnetite of abnormally magnetized rocks might be useful. A similar case in the Allard Lake District, Quebec, was cited by Prof. D. Williams, where massive ilmenite-hæmatite gives negative anomalies but disseminated ore gives positive anomalies. A plea for the examination of the accessory minerals was made by Dr. W. Bullerwell, who indicated that, in Mull, the acid rocks are all normally magnetized. He inquired if their magnetism is less stable than that of the basic rocks, but was informed that their behaviour does not suggest this. On this point Dr. J. Sutton said that valuable data might be obtained from the mixed acid and basic formations of Mull. Replying to a further question by Dr. Bullerwell, Mr. Hospers stated that his suggested time for a change in the field was not based on theory but on observations of consecutive lava flows.

Mr. F. Lowes showed that Graham's argument, repeated by Mr. Creer, which is based on two oppositely magnetized deposits that are contemporary on the basis of their fossil content, does not condemn the idea of a field inversion. A fossil may persist for a million years—a period sufficient to embrace a number of reversals. The discordantly magnetized Welsh Dykes may represent a period of change. Mr. R. Hide pointed out that sedimentary rocks might show the secular change in the past, and the direction of drift during a period of reversal would be an important factor in sustaining or condemning modern theories of the main field.

Summarizing, Prof. Tilley said that many outstanding questions still remain and further data are necessary on sediments and igneous rocks. In particular, a knowledge of the accessory minerals is essential.

J. M. Bruckshaw

# OBITUARIES

## Prof. Philipp Ellinger

Philipp Ellinger died in London on September 12, 1952, after a long and painful illness. He was born in 1887 in Frankfurt am Main, where he spent his early years before proceeding to Munich to study natural sciences under von Bayer and Roentgen. He took the D.Phil. degree in chemistry at Greifswald under von Auwers in 1911, and passed on to Heidelberg to study medicine and finally graduated D.Med. in 1913. During the First World War he served as a medical officer in the German Army and returned after the cessation of hostilities to Heidelberg, where he occupied successively the position of assistant, lecturer and deputy director in the Pharmacological Institute there and served under three distinguished pharmacologists, Gottlieb, Wieland and Heubner. Towards the end of 1931 he was called to the chair and directorship of the Pharmacological Institute at the Medical Academy of Düsseldorf. By 1933, however, the political situation in Germany rendered his position untenable, and he found refuge in Britain, where, at the Lister Institute, he took up his research problems again and remained until his retirement in June 1952.

Ellinger's early work was largely in the field of toxicology; but by the time he came to Britain he had already turned to physiology, had published important work on renal function and had invented a technique for intravital microscopy which employed fluorescent dyes. With Koschara in 1933 he worked on flavin pigments which he isolated from whey, and thus he contributed materially to the discovery and identification of lactoflavin (riboflavin) as a member of the vitamin B complex and helped to establish the presence of this biologically important material as a constituent of Warburg's yellow enzyme. In 1937 he visited Egypt on behalf of the Medical Research Council to study pellagra, and returned to complete his investigations in 1938. During the second visit he became seriously ill and never fully recovered his normal health in after-years. As a result of the studies carried out in Egypt he concluded that the occurrence of pellagra resulted from two concomitant but independent factors. First, that a condition of latent pellagra arose from malnutrition, or malabsorption, due to the presence of intestinal infections. He believed that external factors such as hard physical work brought on an active pellagra when the latent state had developed. Ellinger examined the effects of a deficiency of different members of the vitamin B group on the excretion of abnormal porphyrin pigments, and just before the Second World War attempted to isolate and identify the light-sensitizing materials in buckwheat. Somewhat later (1942) he interested himself in the metabolism of nicotinamide in man and animals, and studied very thoroughly, during the next few years, the elimination of nicotinamide methochloride in normal and nicotinamide-deficient persons. The results of these researches revealed that the intestinal bacterial flora can form a very significant extra-dietary source of nicotinamide. His last investigations, on the heredity of the nicotinamide methylating mechanism in the rat and the elaboration of a new spectrophotometric method for tracing unknown urinary metabolites, remained unfinished.

Ellinger was highly cultured and widely travelled, and had many of the qualities of the typical German

*Gelehrter*, particularly the encyclopædic knowledge derived from much reading. He had a special love for pictures and a keen appreciation of the fine arts.

He was never a robust man, and during the closing years of his life, when his health deteriorated rapidly, his colleagues were deeply impressed by his fortitude, his complete occupation with the problems in hand and his absolute disregard of his own general frailty. Ellinger is survived by his wife, two sons and a daughter.

W. T. J. MORGAN

WE regret to announce the following deaths:

Prof. Jules Haag, director of the Institute of Chronometry at Besançon and non-resident member of the Paris Academy of Sciences, on February 16, aged seventy.

Dr. T. A. Jaggar, since 1940 research associate in the Hawaii National Park and an authority on volcanology, aged eighty-one.

Prof. Sergius Winogradsky, For.Mem.R.S., the distinguished bacteriologist, on February 24, aged ninety-six.

# NEWS and VIEWS

## Physical Chemistry in the Chester Beatty Research Institute, London: Dr. J. A. V. Butler

DR. J. A. V. BUTLER, who has just been appointed to the recently established chair of physical chemistry in the University of London tenable at the Chester Beatty Research Institute (Institute of Cancer Research, Royal Cancer Hospital), graduated in 1921 in the University of Birmingham, of which he became D.Sc. in 1927. During 1922–27 he was assistant lecturer in chemistry at the University College of Swansea, and in 1928 was awarded the Meldola Medal of the Institute of Chemistry. Then for the next twelve years he was lecturer in chemistry in the University of Edinburgh, and later spent two years as Rockefeller Research Fellow at the Rockefeller Institute, Princeton, N.J. He played an important part in the early days of the British Commonwealth Scientific Office in Washington, of which he was executive officer during 1942–44. In 1945 he became Courtauld Research Fellow at the Courtauld Institute of Biochemistry, Middlesex Hospital Medical School, London. Dr. Butler joined the Chester Beatty Research Institute in 1949, from which time he has devoted himself, with his school, to the application of the methods of biophysical chemistry to the problems of growth, the mode of action of ionizing radiations, and the mechanism of interaction of carcinogenic agents with nucleic acid and nucleoprotein.

Prof. Butler has contributed a notable series of papers and other publications to the scientific literature. A specially distinguished essay was his "General Thermodynamical System of Gibbs" (in "A Commentary on the Scientific Writings of J. Willard Gibbs", ed. F. G. Donnan and A. Haas, Yale 1936). A successful general work is his "Man is a Microcosm" (1950), and Prof. Butler has more recently acted as editor of "Electrical Phenomena at Interfaces" (1951), and (with Prof. J. T. Randall) of the important series "Progress in Biophysics and Biophysical Chemistry". His interest in the application of physical chemistry to biological problems is a new and significant development which the establishment of this new chair is intended to encourage and extend.

## William Froude Memorial Fund

FOLLOWING a suggestion made at the Sixth International Conference of Tank Superintendents, held in Washington, D.C., during 1951, the Council of the Institution of Naval Architects has been considering a proposal to commemorate the pioneer work of William Froude, F.R.S. (1810–79), a pioneer in ship model research and naval architecture generally. His main work was carried out for the Admiralty, and in 1872 he undertook the building of an experimental tank for ship research at a site near Torquay, Devon, this being the first tank of its kind in the world. It has been decided that the memorial should consist of two parts: the erection of a bronze plaque at a suitable point (in a country lane) nearest to the site of the experimental tank; and the publication of a volume containing all Froude's published technical papers. The total sum for this is estimated at £2,500, and subscriptions to the memorial fund are invited. It is understood that about half the proposed sum has already been promised. Subscriptions should be sent to the Secretary, Institution of Naval Architects, 10 Upper Belgrave Street, London, S.W.1, from whom all further information can be obtained.

## Finances of Research Associations

A DEBATE was held on March 3 in the House of Commons on the Draft Cotton Industry Development Council (Amendment No. 2) Order, 1953, the chief purpose of which is to increase from £300,000 a year to £450,000 the maximum amount of the levy which the Cotton Board can, with the approval of the Board of Trade, impose, and during the course of the debate numerous tributes were paid to the work and achievements of the Cotton Industry Research Association. The Order will make it possible for the Cotton Board to increase by the amount of the additional levy its contribution to the British Cotton Industry Research Association (Shirley Institute) for the promotion of research, and the Order received warm support from all sides of the House. Nevertheless, and in spite of general recognition that the work of this and of other research associations is already seriously embarrassed by rising costs, the debate was marked by general concern for more information regarding the actual expenditure on research of the research associations and the Department of Scientific and Industrial Research. Some of the questions in the minds of members, such as the possibility of effective development, of overlapping in technical research and of proper liaison between different research associations concerned with natural and synthetic fibres, could not be raised under the terms of the debate. It was clear that members wished to be satisfied that the considerable sums of money concerned are, in fact, being wisely expended and without waste. The debate, in fact, testified to the value of more independent scrutinies of the work of the research associations such as has already been conducted for the British Leather Manufacturers' Research Association.

## Russian Institute of Scientific Information

A new Institute, to be known as the Russian Institute of Scientific Information, has been established in the U.S.S.R. for the systematic supply of information from home and foreign sources relating to scientific and technical progress (*Vestnik Akad. Nauk*, 10, 92; 1952). Its main purposes, as specified by the U.S.S.R. Academy of Sciences, are: beginning with 1953 to publish an abstracting journal thoroughly covering world literature in mathematics, physical and chemical sciences, and from 1954 to extend its work to deal with biology, geology, geography and technology (engineering); to compile and publish reference books and bibliographies; to compile subject (thematic) reviews on developments in individual branches of science and technology in the U.S.S.R. and abroad; and to undertake translations and duplicating (photostating, etc.) work of journal articles as required by national institutions and industrial concerns. Three main divisions have been constituted as follows: scientific information work and editing of abstracts (referata); industrial publication; and administrative, etc. The Director of the new Institute, who is appointed by the Academy Presidium, is D. Yu. Panova.

## Twenty-fifth Anniversary of the Discovery of the Raman Effect

A meeting of the members of the Indian Association for the Cultivation of Science was held on March 7 in the premises of the Association at Jadavpur to celebrate the twenty-fifth anniversary of the discovery of the Raman effect; Prof. M. N. Saha was in the chair. The sequence of events leading to the discovery of the Raman effect on February 28, 1928, was first narrated briefly by Prof. S. C. Sirkar, with the help of slides and demonstrations. Prof. Saha then pointed out that the discovery was one of the most important in science of this century and that not only the Association but also the whole of India took pride in the fact that such a discovery was made in the laboratories of the Association. A resolution congratulating Prof. C. V. Raman on the anniversary was passed and forwarded to him.

## The United Nations Organization

Two recent publications by the United Nations Organization have been designed to direct popular attention to the activities of the Organization. The first, "Looking at the United Nations", gives a pictorial cross-section of the United Nations up to the end of 1951. Although only a brief sampling of the 34,000 pictures in the photo library of the United Nations Department of Public Information, they cover most of the important activities of the Organization during the past six years. The second, "United Nations in Pictures", has been compiled from picture features which have appeared in recent issues of the *United Nations Bulletin*. The picture stories in the booklet are grouped under general subject-headings including peace, security, economic progress, social advancement, the work for subject peoples and the development of international law. Copies of both booklets may be obtained from H.M. Stationery Office, London.

## The Gannet in New Zealand

Apparent changes in the gannet population of New Zealand led to a desire that a census be taken to ascertain past population trends and to provide a basis for discussion of future changes. In 1946–47 the Ornithological Society of New Zealand adopted the gannet census as a project for co-operative study during the 1946–47 breeding season, and C. A. Fleming and K. A. Wodzicki were appointed organizers of the survey. They have now prepared a paper giving details of the census project and a summary of available data on the past history of the gannetries (*Notornis*, 5, No. 2; October 1952). The paper shows that there has been a general increase in the New Zealand gannet population during the past century. The reason for the suggested increase in total population cannot be stated. The Maoris used young gannets as food; but this was probably on a small scale. During the nineteenth century, Maori use of gannets became negligible. The gannet was protected in the Animal Protection Amendment Act, 1910. The effect of legal protection cannot have been great for there was no habitual use of gannets as bait by fishermen, or as food, before the Act was passed. There is no record of destruction on a large scale. The use of gannet guano on a commercial scale was once contemplated; but it has never been taken regularly in large quantities. A little guano is still removed from some gannetries; but there is no evidence that this affects the success of breeding. The change in man's influence on gannets is not enough to account for their increase in New Zealand. The apparent trend is perhaps due to fundamental changes in the ecology of the sea, possibly of a cyclic nature.

## Seasoning Behaviour of Indian Timbers

In *Indian Forest Bulletin*, No. 154 (new series), M. A. Rehman, of the Wood Seasoning Branch of the Forest Research Institute, Dehra Dun, discusses "The Seasoning Behaviour of Indian Timbers" (Part 1; pp. 5+1 plate; Delhi: Manager of Publications, 1952; 8 annas or 9*d*.). In the days before the Research Institute came into being at Dehra Dun, seasoning of timber was practically unknown. Green timber from the forests, by the time it reached the market, may have become air-seasoned to a small extent, but usually not sufficiently to withstand the trying conditions of the climate in the variety of species now used in wood-work. A considerable amount of data on the air- and kiln-seasoning properties of Indian woods has been collected by the Wood Seasoning Branch during the past thirty-five years in the experiments carried on at Dehra Dun, as well as in the field in other parts of the country. Systematic accounts of the results of most of the air-drying tests have been published from time to time, but little information has so far been published by the Institute on kiln-drying studies. The object of this publication and subsequent parts is to assemble all the available information on air- and kiln-drying timbers of important Indian timber trees. The importance of adopting proper methods of seasoning wood before use is emphasized. The advantages of seasoning are discussed. The air and kiln seasoning of fir is described, and the kiln-drying schedule recommended for 1-in. planks of fir and for several other light hardwoods suitable for packing-cases is given.

## Fossil Mammals of Africa

Two further papers based upon material collected by the British–Kenya Miocene Expedition have appeared in the series 'Fossil Mammals of Africa", published by the British Museum (Natural History).

The first, No. 4, is on "Miocene Anthracotheriidæ from East Africa", by D. G. MacInnes (pp. 24+4 plates, 1951). The author comments on the fact that most of the East African fossil material is fragmentary, possibly as the result of scavenging animals attacking the dead bodies. The presence of a well-preserved skull and also some fragments of others enables the author to establish satisfactorily, and in some detail, a new species *Brachyodus æquatorialis*. The material included some limb bones and metapodials which, while not directly associated with the skulls, can reasonably be attributed to the same, or a closely allied species. Further information on *Hyoboops africanus* is also provided.

The second, No. 5, by W. E. Le Gros Clark and D. P. Thomas, is based on specimens of "The Miocene Lemuroids of East Africa" (pp. 20+3 plates, 1952). The material includes mandibular and maxillary fragments, a brain case and an endocranial cast. It all belongs to the sub-family Galaginæ and to the genus *Progalago*. The name was given because, when the type species *P. doræ* was described by D. G. MacInnes, it was considered that it represented a group from which the modern *Galago* might well have been derived. The paper adds considerably to our knowledge of the type species and also describes two further species of the genus, and the authors comment that none of the new evidence is contrary to the suggestion made with regard to the relationship of the genus with *Galago*. The plates accompanying both papers are of a high quality and very well reproduced.

### Radioactive Starch and Hexose Sugars

THE preparation of radioactive starch, glucose and fructose from tobacco leaves after assimilation of $^{14}CO_2$ has been described by H. K. Porter and R. V. Martin (*J. Exp. Bot.*, 3, 9, 326; 1952). In the photosynthesizing process, the experimental control of which is described, at least 80 per cent of the $^{14}CO_2$ supplied appeared in the leaves as starch and sugar and more than 80 per cent of the radioactivity was accounted for in these carbohydrates. Small amounts of radioactive carbon were also found to be incorporated in the protein, cellulose, hemicellulose and polyuronide components of the leaf.

### 3-Indolylacetonitrile: an Important Plant Hormone

INVESTIGATIONS of the recently discovered and important plant growth hormone, 3-indolylacetonitrile, and of 3-indolylacetaldehyde (reported to be present in plants), and both now available as pure synthetic substances, are described by J. A. Bentley, S. Housley and A. S. Bickel (*J. Exp. Bot.*, 3, 9, 393, 406; 1952). As measured by their effects on cell-elongation in the coleoptile of *Avena*, 3-indolylacetaldehyde is considerably less active than 3-indolylacetic acid. An acidic substance is produced by the aldehyde during the period of assay, and in some experiments the aldehyde's activity could be accounted for on the assumption that it is transformed into 3-indolylacetic acid. Other evidence indicates that the aldehyde itself is either inactive or inhibitory. The nitrile, which is considerably more active than 3-indolylacetic acid, shows little production of acid during the period of assay. As the nitrile is destroyed by treatment with alkali but not with acid, the authors consider that earlier work on the identification of auxins in plants by their acid and alkali sensitivity should be re-examined. By using the *Avena* straight-growth test, in which the nitrile shows activity, evidence has now been obtained that it is present in various members of the Cruciferæ. Transport of the nitrile, like that of the acid, is polar, but it is considered that the nitrile can reach the growing cells as easily, if not more so, than the acid —a finding that is important in attempts to postulate the mechanism of nitrile action. The nitrile is less active in the *Avena* curvature test than the acid, and is inactive in the pea curvature and straight-growth tests except at high concentrations. It is inactive or only slightly active in the inhibition of lateral buds, in the inception of roots, and in petiole abscission at the concentrations tested. It is also less active than the acid in root inhibition in cress, but about as active in *Avena*. It is of about the same activity as the acid in the development of parthenocarpic fruit and the stimulation of cambial activity.

### Total Eclipse of the Sun on June 30, 1954

A SUPPLEMENT to the "American Ephemeris and Nautical Almanac" for 1954 has been issued by the U.S. Naval Observatory, entitled "Total Eclipse of Sun, June 30, 1954" (pp. 42. Washington, D.C.: Govt. Printing Office, 1952; 40 cents). It is designed primarily for use along the path of the total phase of this eclipse, which will be visible in the United States, Canada and Greenland; but data are also given for the Atlantic Ocean and Europe. The maps provide local circumstances of the eclipse for all places within the limits of the eclipse region extending from the southern limit of the eclipse to lat 73° N., and from long. 170° W. to 80° E. Two tables give the necessary data for finding the position of the central line at various heights above sea-level and in the ionosphere up to 300 km., and also the duration of totality on the central line and the width of the path, at the earth's surface and at heights ranging from 100 to 300 km. The "American Ephemeris and Nautical Almanac" for 1954 gives a map for the complete eclipse area and also the Besselian elements and other usual eclipse data not given in the supplement, including an example of the calculation of the circumstances of the eclipse for a given place.

### Catalogue of Horrebow Star-Pairs for the determination of Northern Latitudes

A CATALOGUE of star-pairs for northern latitudes from 55° to 70° for astronomic determination of latitudes by the Horrebow–Talcott method has been compiled by Pentti Kalaja (Suomen Geodeettisen Laitoksen Julkaisuja, No. 41. Pp. 191. Helsinki: Finnische Geodätischen Institute, 1952). The stars of Horrebow-pairs appearing in this catalogue have been selected from the "General Catalogue of 33,342 Stars for the Epoch 1950", by Benjamin Boss, and in the selection of the stars certain principles have been observed, among which the following may be noticed. The right ascensions of the stars must lie between 17h. and 24h. and their declinations between 30° and 85°. Stars of magnitudes between 3 and 7 only are admitted; experience has shown that it is not advantageous to use very bright stars, although their declinations are generally determined with great accuracy. The parallax of the star used must be less than 0·05″ and the probable error of the declination must be smaller than ± 0·40″. In addition, double stars, of which the distance from each other lies between 0·1″ and 6″ and the difference in magnitude is less than 3 m., have been rejected. Double stars which have circular or elliptical motion, and those which have peculiarities in proper motion, have also been excluded. As the catalogue is intended for latitudes 55°–70° N., which includes nearly all of Finland, Sweden and Iceland, most of Norway, Denmark, Scotland and Alaska, the greater portion of Canada, and most of the Soviet Union, except the northernmost parts, the mean declinations of the stars must lie between 55° and 70°. Other conditions are that differences of magnitude of the stars must not exceed 2 and differences of right ascension for the stars of 1950·0 must lie between 2m. and 15m. More than 176 pages of tabular matter are included in the catalogue.

### Earthquake Waves reflected at the Earth's Core

PROBABLY the first mention of a transverse wave reflected at the boundary of the earth's core is to be found in a paper by F. J. Scrase in 1931 ("The Reflected Waves from Deep Focus Earthquakes", *Proc. Roy. Soc.*, A, 132; 1931). These pulses were observed by K. Wadati for an earthquake on November 13, 1932, and H. P. Berlage observed the waves at Amboina, his results being published in 1937 and 1939. S. W. Visser also noted the waves on the Amboina records of an earthquake on June 29, 1934, his book being published in 1937. R. A. Garrick (*New Zealand J. Sci. Tech.*, B, 31, No. 2; September 1949) has noted these pulses on New Zealand seismograms at epicentral distances of 0·92°, 2·25° and 3·45° for the earthquake of January 15, 1948, and has tabulated the readings. These results extend the observations by E. Tillotson (1939) and form a very valuable check on the "Seismological Tables".

### Iron and Steel Institute: Awards

THE following awards have been made by the Iron and Steel Institute: *Bessemer Medal for* 1953, to R. Mather, of Skinningrove Iron Co., Ltd., and past-president of the Institute, for his distinguished services to the Institute and to industry; *Sir Robert Hadfield Medal for* 1953, to W. E. Bardgett, research manager of the Central Research Laboratories of the United Steel Companies, Ltd., in recognition of his contribution to the development of alloy steels, with particular reference to steels for service at elevated temperatures; an *Andrew Carnegie Silver Medal for* 1952, to Dr. E. T. Turkdogan, now with the British Iron and Steel Research Association, for his research on slag-metal reactions reported in various papers, his results being written in collaboration with Dr. W. R. Maddocks (*J. Iron and Steel Inst.*, July 1949, and June and September 1952); *Ablett Prize for* 1952, jointly (£50 each) to Dr. S. A. Burke and G. A. Sparham, of the British Coal Utilization Research Association, for their paper on the automatic control of coal feed in steelworks gas-producers (*J. Iron and Steel Inst.*, November 1952). No award was made of the Williams Prize.

### Grants of the U.S. National Science Foundation Awards

THE National Science Foundation has recently made seventy-eight grants, totalling 685,200 dollars, to institutions in the United States for research in the biological and the physical sciences and for the support of studies and conferences on science and scientific education. This is the second group of awards to be announced under the Foundation's programme for the support of basic research, bringing the total number of research grants made this year to one hundred and thirty, worth 1,340,650 dollars. The fields included are astronomy, chemistry, developmental biology, earth sciences, engineering, environmental biology, genetic biology, mathematics, microbiology, molecular biology, physics, psychobiology, regulatory biology, research education in the sciences, scientific information, studies in science and systematic biology. The duration of research grants in this latest group of awards ranges from eight months to three years, with an average length of 1·6 years; the average grant amounts to 5,475 dollars a year.

### University of London: Appointments

THE following appointments have been made in the University of London: Mr. J. Durbin, lecturer in statistics at the London School of Economics and Political Science, to the university readership in statistics tenable at the School; Dr. D. A. McDonald, senior lecturer in physiology at St. Bartholomew's Hospital Medical College, to the university readership in physiology tenable at the College; Mr. A. E. Smailes, reader in geography at University College, London, to the university readership in geography tenable at Queen Mary College.

### Announcements

DR. KEITH MURRAY, rector of Lincoln College, Oxford, has been appointed chairman of the University Grants Committee in succession to Sir Arthur Trueman, who is retiring on October 1 for reasons of health.

THE second international conference on the biology and cultivation of the mushroom will be held at Gembloux, Belgium, during June 16–24. Further information can be obtained from the honorary secretary, Mlle. L. Engels, C.E.R.E.C., Institut Agronomique de l'État, Gembloux.

THE spring conference of the Institute of Metal Finishing will be held in the Hotel Majestic, Harrogate, during April 22–25. The conference will begin with an informal reception and dinner on April 22, and during the next three days there will be four technical sessions on, respectively, organic and other non-electrodeposited coatings, electrodeposition, fundamental electrode processes and shop practice. Further information can be obtained from the Conference Secretary, 32 Great Ormond Street, London, W.C.1.

THE Textile Institute is offering a Cotton Industry War Memorial Trust Scholarship, of maximum value £950, for a three-year course in textile technology at an advanced level, with provision for industrial training and experience of a special character in Britain or overseas. The closing date for applications is April 30. The Institute is also offering a new scholarship, to be known as the 'Peter Coats' Scholarship, since it has been established by the will of the late Mr. Coats, of Paisley, and this award, which is of maximum value £200, is intended to enable a person who has already been awarded or promised a scholarship in advanced textile technology to pursue a year of full-time study preparatory to taking up his main course at a university or college. The closing date for applications is May 30. Candidates for both these awards must be male British nationals less than twenty-four years of age. Application forms and further information can be obtained from the General Secretary, Textile Institute, 10 Blackfriars Street, Manchester 3.

# RECENT ADVANCES IN MICROBIOLOGICAL METHODS

VARIOUS aspects of recent advances in microbiological methods were discussed at a joint meeting of the Society for Applied Bacteriology and the Microbiological Group of the Society of Chemistry and Industry, which was held at the Institution of Civil Engineers, Great George Street, London, on January 14. Dr. J. G. Davis presided at the meeting.

Prof. M. Stacey opened the meeting with a paper on the "Chemistry of Gram Staining and of the Feulgen and Dische Reactions for Nuclear Material". Mention was made of the need to put the important microbiological and histological staining techniques on to a firm chemical basis. Profound chemical differences exist between the two groups of organisms: the Gram-positives, which can be stained by Gram's basic fuchsin – iodine technique; and the Gram-negatives, which do not retain the stain on being washed with alcohol. By means of bile salts Gram-positives can be stripped of their surface material, leaving a Gram-negative cytoskeleton. When this is kept under reducing conditions, it is found that magnesium ribonucleate from the bile salt extract or from other sources will combine with it in such a way that the Gram-positive state can be restored. It is considered that the dye-retaining complex is a magnesium ribonucleoprotein located near the cell surface of Gram-positives. Gram-negatives, on the other hand, although possessing ribonucleic acids, have surface material composed of phospholipids, protein and polysaccharides.

The significance of ribonucleic acid in the Gram-complex can be emphasized by the use of ribonucleases and autolytic enzymes from the cell. Cells rendered Gram-negative by the action of lytic enzymes are difficult to reconstitute unless they are first treated with the protein component of the Gram-complex, followed by addition of the magnesium ribonucleate. Mechanical disruption of cell surfaces completely destroys the possibility of reconstituting the Gram-complex.

Deoxyribonucleic acid plays no part in the Gram-complex; but its deoxy sugar component is implicated in both the Dische diphenylamine and Feulgen reactions for nuclear material. The Dische reaction is explained by the finding that 2-deoxypentoses under the strongly acidic conditions of the test are transformed into ω-hydroxy lævulic aldehyde that combines with diphenylamine to give a blue dye which, in the Spekker, has a characteristic band with a single peak.

The Feulgen test can be explained as a result of extensive investigations on the properties of 2-deoxy sugars. Under mildly acidic conditions the 2-deoxyribofuranose component of the nuclear material readily loses some of the groups attached at the reducing carbon atom, and the sugar ring opens to give an aldehydo-sugar. This gives an intense insoluble dye with the Schiff's reagent used in the Feulgen test. Further implications of the known behaviour of deoxy sugars were mentioned. In the discussion which followed, Prof. Stacey was unable to explain some of the observations of various investigators during Gram-staining, and he mentioned that magnesium is not completely specific in the Gram-replating technique.

The next speaker was Dr. E. Windle Taylor, who described the "Use of the Membrane Filter in the Bacteriological Examination of Water". He said that collodion membranes not only retain all micro-organisms from a large volume of liquid, but can also be placed in contact with a substrate which conveys nutrients through the pores to the deposited bacteria so that they can be cultivated *in situ*. The substrate takes the form of an absorbent pad which can be soaked with concentrated nutrient. The use of the apparatus is quite simple, but sterilization of the membranes requires great care. After much trial it has been found possible, without harming the membranes, to autoclave them for ten minutes at 10 lb./sq. in. pressure if they are stacked alternately with absorbent pads and the pile wrapped in kraft paper.

The main lines of investigation were to ascertain whether the apparatus and technique could be applied to media and methods commonly employed in Britain for the bacteriological examination of water, and this has been established in a satisfactory manner. The amount of liquid that can be filtered in a given time through each membrane depends upon the amount of suspended matter, and varies from two litres in ten minutes for tap water to a quarter of a litre in one hour for sewage effluent. Double-strength nutrient broth is used for colony counts, and figures obtained closely follow the corresponding agar counts, while in certain circumstances, such as pure chalk waters, larger volumes can be examined. Colonies first become visible after eight hours incubation and reach a maximum after eighteen hours. MacConkey broth can be used for the coliform examination, if made up in triple strength but with bromcresol-purple indicator of twelve times strength. The lactose-fermenting colonies are clearly distinguishable as pale yellow colonies on a blue background. Colonies are first seen after eight hours incubation, and a maximum number is reached after twelve hours incubation. Preliminary resuscitation of bacteria with nutrient broth and the achievement of direct *Bact. coli* counts are matters for further study.

Pathogenic bacteria have been successfully isolated by membrane filtration by cultivating the membrane in selenite broth, thus saving a large volume of medium; no success has yet been achieved in producing typical colonies of enteric organisms on a membrane and pad impregnated with a liquid form of Wilson–Blair medium.

The chief advantages of the technique are concentration of organisms, removal of inhibitory substances in the water itself, saving of glassware and media and, in the case of the coliform test, the avoidance of false presumptive results due to spore-forming anaerobic lactose-fermenters. There appears to be a field of exploration along three main lines to assess the applicability of filter membranes in the bacteriological examination of water: for examining a series of samples, as in a river or a lake survey; where a rapid result is required; and for isolating pathogenic organisms from sewage effluents and polluted waters.

In the lively discussion which followed, various speakers mentioned their own experiences with the membrane filters and the commercial availability of various types, and the general feeling was reached that the filters would prove very valuable.

In the next paper, Dr. L. A. Allen described the "Enumeration of *Bacterium coli* and of *Streptococcus fæcalis*". Growth of *Bact. coli* on bile salts – lactose agar at 44° C. has been found to be conditioned by a number of factors. The temperature of 44° C. is critical for this organism, and an accurately controlled water-bath is essential. The inclusion of phosphate in the medium reduced the count of all strains tested, and some strains were virtually unable to grow under these conditions. When the bacteria are suspended in water, the proportion of the total population able to grow on the bile salts medium at 44° C. tends to decrease as the period of suspension is prolonged. This result of attenuation can be largely overcome by dividing the medium into two parts, each of double strength—lactose broth; and a solution containing the bile salts, indicator and agar —and subjecting the inoculum to a short period of incubation in the lactose broth at 37° C. before adding the second part of the medium and incubating at 44° C. 'Resuscitation' for one hour in this way results in a count on bile salts – lactose agar at 44° C. which approximates to the count on Yeastrel – glucose agar at 37° C. The film of agar is formed in a rotating bottle which can afterwards be directly immersed in a water-bath. The temperature cannot be controlled with sufficient accuracy if Petri dishes are used.

Evidence has accumulated in recent years that *Str. fæcalis* may be a useful indicator of fæcal contamination when used in conjunction with conventional tests for coliform bacteria. As a result of a similar study of the growth of this organism on 'Yeastrel' – glucose azide agar, a technique has been formulated for obtaining a colony count on this medium at 45° C. *Str. fæcalis* was found to be so sensitive to neutral red that it was necessary to leave this indicator out of the medium altogether. Phosphate exerts no depressing action on the count, provided it is not included with the other constituents of the medium before autoclaving. As with *Bact. coli*, 'resuscitation' largely overcomes the inability of attenuated cells to form colonies on this medium.

The principle of resuscitation has been applied to the determination of the most probable number of both organisms for use with samples in which the numbers of bacteria are too small to permit of an accurate colony-count. The resuscitation method has been found to give significantly higher results than existing methods for both organisms, it requires less time for completion, and it is virtually specific for the organism concerned.

Following the comments on this paper, Dr. S. T. Cowan dealt with "Microchemical Methods for the Characterization of Bacteria". He said that the reproducibility of a biochemical test depends on the ability of the organism to produce appropriate enzymes and also on the medium, temperature and duration of incubation, volatilization or utilization of the end-product, and the sensitivity of the test reagents. Bacteria are essentially complex enzyme systems and are most easily studied by letting non-growing cell suspensions act on defined substrates. This principle can be applied to the biochemical tests used in bacteriological laboratories, one enzyme system being tested at a time. Each test depends on the action of a very heavy suspension of the organism: the heavier the suspension, the quicker the reaction; and a minimum density equivalent to $10^9$ *Bacterium coli*/ml. is essential.

Fermentations are carried out by mixing sugar solution, bromthymol blue and bacterial suspension and incubating at 37° C. The method is sensitive and shows acid production by organisms which, in growing cultures, appear to lack fermentative ability. Other tests for glucose breakdown can be adapted to the micro-methods using suspensions. A micro-method for the methyl red test (ability to produce a *p*H of 5 or less from glucose) is being developed. Acetoin (acetylmethylcarbinol) can be detected readily; but, as the enzyme is adaptive, the suspension should be made from growth on a glucose medium. Hydrogen sulphide production can only be observed when there is an adequate source of sulphur available; cysteine hydrochloride is suitable for all the bacteria examined, but the test using cysteine and lead acetate paper is so sensitive that it has little differential value.

Nitrate reduction, the production of indole, and urease are other tests that can be carried out quickly with suspensions and the appropriate substrates. All the micro-methods so far developed are simple to set up and are quick in action; the specificity of the tests depends on the test reagents.

By testing each enzyme system separately, it should be possible to characterize a bacterium by its enzymic formula, much as a serologist characterizes it by an antigenic formula. The micro-methods should be readily adaptable to studies on the availability of different amino-acids.

Numerous speakers commented on the paper, and the useful suggestion was made by Mr. H. B. Hawley that the chromatographic purity of the sugars used by Dr. Cowan should be checked.

Finally, Mr. J. Tramer spoke on "Use of Bacterial Phosphatases in Differentiating Certain Micro-Organisms". Bray and King investigated, in 1943, the production of phosphatase by growing organisms as a possible aid for their differentiation. They assessed the phosphatase activity of a wide variety of species by incorporating phenolphthalein phosphate in an egg medium. The amount of phenolphthalein liberated from the substrate by phosphatase served as an indication of the amount of enzyme produced. They found their relative simple technique of value in differentiating between members of certain genera, but thought the slow rate of hydrolysis of their substrate to be a disadvantage.

Barber and Kuper examined, in 1951, the possibility of distinguishing between pathogenic and non-pathogenic staphylococci by their respective phosphatase reactions. They used phenolphthalein diphosphoric acid which, when suitably incorporated into an agar medium, allowed good differentiation between phosphatase-negative colonies, which were found to be coagulase-negative and therefore non-pathogenic, and phosphatase-positive colonies which proved to be coagulase-positive and only rarely coagulase-negative.

Yet another substrate, disodium *p*-nitrophenylphosphate, has been shown to be useful in the estimation of phosphatase activity. It is colourless in solution but produces, on hydrolysis by phosphatase, free *p*-nitrophenol, which is yellow in neutral and alkaline solution and serves as a measure of enzyme activity. Although not heat-stable, solutions can be Seitz-filtered and incorporated into solid and liquid media. On solid media, colonies of phosphatase-producing organisms will show a yellow colour after a suitable incubation time, and liquid media will turn yellow if such organisms are present. Plates containing media into which disodium *p*-nitrophenylphosphate has been incorporated can be used for streaking, and it has been found practicable to flood inoculated and incubated normal milk agar plates with a small amount of a disodium *p*-nitrophenylphosphate solution. In the latter case, surface colonies of strong phosphatase-producing organisms will turn yellow in a few minutes.

The estimation can be made quantitative by incubating a measured amount of bacterial suspension with a suitably buffered or unbuffered solution of disodium *p*-nitrophenylphosphate for a certain time (half an hour to several hours) and estimating the colour developed in a comparator using permanent colour standards, or photo-electrically. Using such a procedure, a good relationship was found between phosphatase activity and gelatine liquefaction time of Voges–Proskauer positive, methyl red negative Coli-aerogenes organism. *Bact. cloacæ* appears to be in general a non-, or only weak, phosphatase-producer, while *Bact. aerogenes* and also the 44° C. positive type (Irregular VI) are strong phosphatase-producers.

In addition to the degree of phosphatase activity and its correlation to another biochemical reaction, there are certain characteristics of the bacterial phosphatase produced which may be of value in differentiating micro-organisms. Pett and Wynne have shown that the *p*H optimum may be of value in this respect, and it is suggested that the heat stability in certain media and the activity of a cell-free filtrate may also be of use.

---

# CHEMISTRY AND INTER-RELATIONSHIPS OF ENDOCRINE SYSTEMS AND THEIR PSYCHOLOGICAL EFFECTS

An evening discussion meeting on this theme was held on February 26 by the Society for Visiting Scientists at 5 Old Burlington Street, London, W.1, Dr. A. S. Parkes (National Institute for Medical Research, Mill Hill) being in the chair.

Prof. Jean Roche (Collège de France, Paris) spoke first, his subject being the biochemical aspects of hormone actions. One of the major concepts influencing biochemical thought and research in the present century is that of bio-catalysts—substances of great importance profoundly influencing the rate of chemical reactions in the body, and effective in small or minute amounts. Within this general group are substances which were at first thought of as being of a very different nature—vitamins, hormones and enzymes. The demonstration that many, perhaps all, vitamins act by virtue of their intimate association with the enzymes concerned with fundamental metabolic processes in the body is of immense significance.

In the case of the hormones, early work was concerned mainly with their physiological, rather than with their biochemical, actions; the biochemist could approach their study only indirectly by studying their effects on tissue enzymes, and after this action had been shown to be specific, both for the hormone and the enzyme involved. For example, the administration of œstrogens to the castrate female animal produces a marked rise in the alkaline phosphatase content of the uterus, but not of other tissues. Progesterone alone has almost no effect but, given with œstrogens, prevents this rise in enzyme content. Arginase is an enzyme of great importance in the mammals, because of its part in the Krebs cycle for the conversion of ammonia to urea—the main nitrogenous excretion product in this group. More recently, androgens have been shown to increase the concentration of this enzyme in the kidney; the concentration in other organs and of other enzymes in the kidney is not affected. The response is not produced by other sterol hormones without androgenic activity. Similarly, Folley and Greenbaum have demonstrated a marked (hundred-fold) increase in the concentration of this enzyme in the mammary gland following parturition as lactation begins under hormonal influence. These and other observations suggest that tissues can respond by specific enzyme changes in response to specific hormones, and that through such studies the biochemist can make valuable contributions to the least well-known aspect of endocrine function—the mechanism of their peripheral action.

Prof. F. G. Young (Cambridge) suggested that hormones might be defined as substances liberated into the blood stream to produce changes in tissues at a distance. As Prof. Roche had already emphasized, their action is most probably exerted by their effect on the chemical processes of the receptor cells. As a parallel to their marked actions in chemically small amounts, the early workers in this field had difficulty in gaining general acceptance for their concepts as there was reluctance to admit that such physically insignificant organs as the pituitary and adrenal glands and the apparently unimportant islet cells of the pancreas could be of supreme importance to the maintenance of life. Full acceptance was delayed until it was shown that the disastrous results of experimental removal of these 'inner secreting' or endocrine glands could be reversed by injections of potent extracts from them. Even the central nervous system, which at the time when the early observations were made, such as that of Addison in 1855, was thought to be the dominant controlling system, has been shown to depend largely on the maintenance of the correct balance of endocrine activity for its proper functioning. The level of sugar in the circulating blood is largely under hormonal control: a doubling leads to diabetes and severe metabolic upset; a halving to coma, convulsions and death.

Chemically, the hormones are a very heterogeneous group; even in a single gland there is often a multiple secretion rather than a single hormone. Very recently it has been shown that the thyroid, formerly thought to secrete only one effective chemical substance—the iodo-amino-acid thyroxine—probably secretes also the closely related and more active 3′-3-5-tri-iodothyronine.

In conclusion, Prof. Young pointed out that many endocrine glands are derived embryologically from 'barrier' tissues—the ectoderm separating the animal from the external environment, and the endoderm of the alimentary canal coming between the body as a whole and the gut lumen. He postulated that one important action of hormones in the tissues might be concerned with increasing or decreasing the rate at which important metabolites cross the barrier of the cell membranes.

Prof. G. W. Harris (Institute of Psychiatry, University of London) said that the profound effects of the endocrines on the nervous system and behaviour, and more recently the influence of the nervous system on endocrine function, have been known in a general way to those engaged in medical practice for many years. The deliberate experimental study of the extent and mechanism of these inter-relationships is a more recent development. Of the influence of hormones on behaviour, still very little is known except in certain limited fields. The studies of Beach on the modification of animal behaviour under the influence of sex hormones are outstanding in this field. Nervous control of the endocrine glands has been more extensively studied and more is known of this.

Despite the fact that only two endocrine glands—the adrenal medulla and the posterior pituitary—are known to have an anatomically obvious and functionally important direct nerve supply, nervous factors are known to play an important part in endocrine function. Marshall's original investigations on the importance of "exteroceptive factors", such as light and temperature, on the sex rhythms of lower animals, have been confirmed and extended in great detail. More recently the responses of the adrenal cortex under the control of the adrenocorticotrophic hormone of the anterior pituitary have been exhaustively studied. An animal exposed to physical or chemical trauma, or to various procedures such as forced immobilization or loud noises, all presumed to cause mental disturbance and, for want of a more precise term, grouped together as 'emotional stresses', exhibits definite signs of increased adrenal cortical activity. Recent work in Prof. Harris's laboratory seems to indicate that in rabbits the activity of the thyroid gland, under the control of pituitary thyrotrophic hormone, decreases in response to such 'stresses' that are known to activate the suprarenal gland. The clinical impression that emotional disturbance may be a precipitating factor in the onset of human hyperthyroidism is another indication of nervous influence on thyroid function.

There is, therefore, a very considerable body of evidence, from many sources, of nervous and mental influence on endocrine function, mediated mainly via variations in the output of the trophic hormones of the anterior pituitary gland.

The discussion at the meeting centred mainly on the influence of psychological factors on endocrine function. Various speakers commented on the difference in response of the experimental animal and man with respect to thyroid function. Prof. Harris replied that the depression seen in his animals was unexpected in view of the information available about human disease. A species difference was postulated by other members of the audience. Different responses in the same species to similar physical stress accompanied by presumably different emotional states were described; in the ritual fighting of male mice kept together, the blood sugar of the aggressor is elevated, but not that of the attacked animal, though both exhibit violent physical activity.

Dr. Parkes, in his summing-up, re-emphasized the importance of the approach discussed by Profs. Roche and Young—the detailed study of the mechanism of peripheral action of the hormones. For the non-chemical endocrinologist, perhaps the most valuable and promising field for future research is the influence that the external environment, acting through the central nervous system, exerts upon the endocrine state of the organism.

# ANALYSIS OF MECHANICAL AND ELECTRICAL ENGINEERING FAILURES

BEFORE the Second World War the British Engine Boiler and Electrical Insurance Co., Ltd., issued annually a technical report dealing both with original work and with the investigation of engineering failures. Vol. 1 of a new series has just been published, which more than maintains the high standard of its predecessors*. This publication will be found to be of the very greatest interest by all engineers and metallurgists who are concerned with the field common to the two professions.

The first forty-five pages are devoted to a most commendable discussion from the practical point of view of caustic cracking in steam boilers, possibly the most comprehensive treatment which has so far appeared. A very considerable number of cases are discussed in detail, and since neither chemists nor metallurgists are as yet in complete agreement as to the details of the fundamental mechanism involved, and since no reliable means of preventing this dangerous form of deterioration has been developed, these are the more valuable. It is suggested that the best advice that can be offered in the light of present knowledge is that the workmanship of new boilers should be of a high standard, particularly as regards the sealing of the riveted seams on the water side; that care should be taken to avoid over-heating, rapid fluctuations of temperature, and other factors arising under working conditions which may disturb the seams; that special care is required in repair work in connexion with the sealing of such seams; and the maintenance of a minimum caustic alkalinity of the boiler water and the maintenance of a sodium sulphate/sodium hydroxide ratio above 2·5.

A most interesting account by Mr. G. A. Cottell of original work on the sources of error in notched-bar testing concludes this publication. The apparatus is described and the sources of error carefully differentiated; in particular, the influence of the seat between the specimen and the machine has been investigated and a new form suggested which cuts down the loss very considerably and, at the same time, eliminates much of the scatter found under normal conditions. It is shown that the results of such losses may reach as high a value as 25 per cent. It is of more than a little interest that, when using a modified form of specimen or a modified type of test, the yield point is clearly shown, even under notched-bar conditions. A fact of great interest which emerges from this work is the evidence that the speed of fracture exerts a considerable influence on the results. A comparison is made between impact and slow-bend tests on identical specimens, and it is shown that the total work of fracture with the Izod specimen is almost 20 per cent higher in impact than when the specimen is broken slowly. A continuation of this work will be looked for by many.

The remainder of the report is concerned with the examination of twenty-seven cases of service failure, a typical one being that of the brittle fracture of a crane hook, which is referred to strain age-embrittlement in a rimming steel, resulting from the strain and heating due to compression and abrasion. A similar example of strain age-embrittlement in a rimming steel occurred in the case of some boiler rivets, the brittleness being traced to the presence of nitride 'needles'. Such work is in a direct line with the tradition in these reports, since Stromeyer's work on the effect of nitrogen in embrittling steel was carried out in the laboratories of the Manchester Steam Users' Association, now taken over by the Company which has issued this report. Incidentally, the same tradition can be traced in the work on the notched-bar test, a subject on which Schuster carried out considerable research.

* British Engine Boiler and Electrical Insurance Co., Ltd. Technical Report, New Series, Vol. 1. Pp. 212. (From the Company, 24 Fennel Street, Manchester 4, 1952.) 12s. 6d.

The account of these investigations on engineering parts which have failed is very welcome. Only too often, service failures are hidden in the scrap heap, and careful investigation can be of immense value in minimizing the danger of further fractures from the same cause. These investigations cover both the mechanical and electrical fields. In the latter there is also an article by D. C. Bacon on "Excess Current Protection of Electric Motor Circuits". Among the failures which are reported are those due to the cracking of a riveted seam due to excess riveting pressure, tube failures, butt-welded joints, failure of turbine blades and shaft, fracture of a steam engine crank-shaft, an accident to an electric goods-lift, defective squirrel-cage motor-rotors, the disruption of a hydro-extractor, and the explosion of an air vessel. In all, these reports provide a very considerable amount of information which should be of value both in design and in the maintenance of mechanical and electrical equipment.

The presentation of this work is more than good, the illustrations and micrographs are excellent, and at the low price at which it is issued should appeal to a very wide range of readers. F. C. THOMPSON

# UNIVERSITY OF WITTENBERG (1502–1952)

THE Martin-Luther University of Halle-Wittenberg, in the East Zone of Germany, held a celebration during October 18–25, 1952, to mark the four hundred and fiftieth anniversary of its foundation at Wittenberg, nearly two hundred years before the separate foundation of the University at Halle, with which it was merged on reopening in 1815 after being closed in 1813 by Napoleon. The pro-rector, Prof. Leo Stern, acted for the rector, Prof. Rudolf Agricola, who was absent through illness. The following details are given in a letter from one of the West Zone delegates.

The opening ceremony was in the Theatre of Peace at Halle. A colourful scene was provided by the university professors, deans, pro-rectors and rectors in their robes. The celebration on Sunday, October 19, took place in the town church of Wittenberg; Prof. Aland gave the address, and at a church service in the afternoon the sermon was preached by Bishop Dibelius. The ceremony was attended by Hungarian and Roumanian bishops, by a representative of the Chinese Christian Reform Movement, and by the Rev. Edward Charles, from Great Britain. On October 20 there was a function, at which scientific addresses were given, at the Institute for German History, a student youth demonstration in the market, and musical performances (Handel, Bach, Brahms and others). On the following day a special meeting of the Leopoldina Academy was held, with lectures and demonstrations on the theme "Der schwerhörige Mensch". The birthplace of the Leopoldina Academy—Schweinfurt in the West Zone of Germany—was officially represented by its mayor, Dr. O. Schön, and by Dr. J. Helfrich, who had already represented his town at Halle for the tercentenary of the Leopoldina Academy in February 1952 (see *Nature*, 169, 576, and 170, 1105; 1952), and they were most warmly received. There followed numerous parallel sittings of the different faculties, with exhibitions. Receptions were held by members of the East Zone Government, by the regional and civic authorities and by the University Senate, and a performance was given of Handel's opera "Tamerlano". R. C. H. YOUNG

# FORESTRY RESEARCH AND ORGANIZATION

TWO papers read at the Sixth British Commonwealth Forestry Conference, held in Canada last year, and now published by the Forestry Commission (London: H.M.S.O., 1952), deserve to be more widely noticed for the scientific importance of their message. The first was by Mr. J. N. R. Jeffers, of the Forestry Commission, London, who discussed the use of statistical methods in forest research. "To-day," he said, "the handling of figures has become a necessity; they are required for administration, management and research, and their collection, analysis and interpretation have become part of the forester's everyday work." The functions of these methods are to provide a sound basis for the design of experiments, to summarize data so that they can be correctly and readily interpreted, and to give an estimate of the probability that the effects indicated by the results are true effects. Statistical methods have become indispensable tools of forest research. It is now a question of making more foresters familiar with them and of asking statisticians to develop new methods when the existing ones are inadequate.

It may be pointed out, in passing, that this is more applicable to the research officer, for the forester's everyday work is, or should be, out in the forests and woods studying the methods of growth and well-being of his trees and their several requirements from the practical sylvicultural point of view on the ground. His job is to produce the timber, etc., of the future by practical sylviculture and constant supervision on the ground. Statistics, though necessary, will not do this.

The other paper was by Mr. N. V. Brasnett, on the "Organization of Sustained Yield in previously Unmanaged Forests". He stated: "For periods within the physical rotations of the species which comprise them, mature, unmanaged forests can be assumed to be in a state of dynamic equilibrium. Large old trees are generally in excess of medium-sized and small trees of the same species, which only have an opportunity of entering the top canopy as overmature trees die. Because no increment is harvested, it has slowed down until it is practically balanced by decay. The smaller trees are not all necessarily younger than the large ones, but may merely be suppressed and even capable of responding to release. Abundant seedlings are liable to appear on the forest floor in most years, but most of them fade away in a few years, leaving only individuals to survive in gaps here and there". The British have the greatest experience in dealing with large areas of tropical and sub-tropical, previously unmanaged forests. British foresters in India for nearly ninety years have been studying and wrestling with the problem of introducing an orderly management and a sustained yield in forests of these types, and a great deal of valuable sylvicultural knowledge has been gathered. The numerous working plans in force throughout India furnish evidence of the advanced position attained. Mr. Brasnett's paper deals with the various problems entailed in introducing a detailed management into the previously unmanaged forest.

# A NEW METHOD OF MEASURING SPERM SPEEDS

By Lord ROTHSCHILD

Department of Zoology, University of Cambridge

IN Chandrasekhar's review on "Stochastic Processes in Physics and Astronomy"[1], the following footnote occurs on p. 89: "Fürth made systematic counts of the number of pedestrians in a [street] block every five seconds. . . . It is amusing that by systematic counts of the kind made by Fürth it is possible actually to determine the average speed of a pedestrian!" The principle involved in such determinations is known as probability-after-effect, and it occurred to me that if the average walking speed of a pedestrian can be determined by this method, the same should apply in the case of spermatozoa, though the latter move in three or in certain circumstances two dimensions, whereas in Fürth's problem the pedestrians only moved in one dimension, that is to the right or the left.

Very little is known about the relationship between the speeds at which spermatozoa swim and their fertilizing capacity, or about the effects of changes in the physical and chemical properties of the medium on sperm movement. These gaps in our knowledge are mainly due to the difficulties which have been experienced in measuring the speeds at which spermatozoa swim. Hitherto such measurements have presented great problems, mainly because photographic methods are not readily applicable to dense sperm suspensions. If the suspensions are diluted sufficiently for photography, the spermatozoa may exhibit pathological changes unless protective substances, which interfere with the measurements, are added to the medium. The electrical method of measuring sperm activity cannot be applied to human spermatozoa because the number of sperm per millilitre of ejaculate is not sufficient to cause the 'wave formation' observed in bull and ram semen, upon which the method depends[2]. Recently, Bosselaar and Spronk[3] have reported a new way of measuring what they call the 'motility' and concentration of spermatozoa. Apart from the objections made to the method by the authors themselves, no estimates of sperm speeds are given in that article.

One can, of course, take a high-speed cinemicrograph of a dense suspension of spermatozoa and then project the film frame by frame on to squared paper, marking the consecutive positions taken up by individual spermatozoa and joining these points together by straight lines. The total length of these lines divided by the overall magnification and the duration of the film gives the speed of each spermatozoon. This process is much too slow and expensive for regular use, though it has been used for verifying the experiments described in this communication; moreover, the person joining up the consecutive positions of sperm heads may have to make difficult decisions as to where a spermatozoon on frame 1 has got to on frame 2. One experiment lasting 30 sec., which takes $2\frac{1}{2}$ hr. to analyse by the new method, takes about a week to analyse by examination of high-speed cinemicrographs.

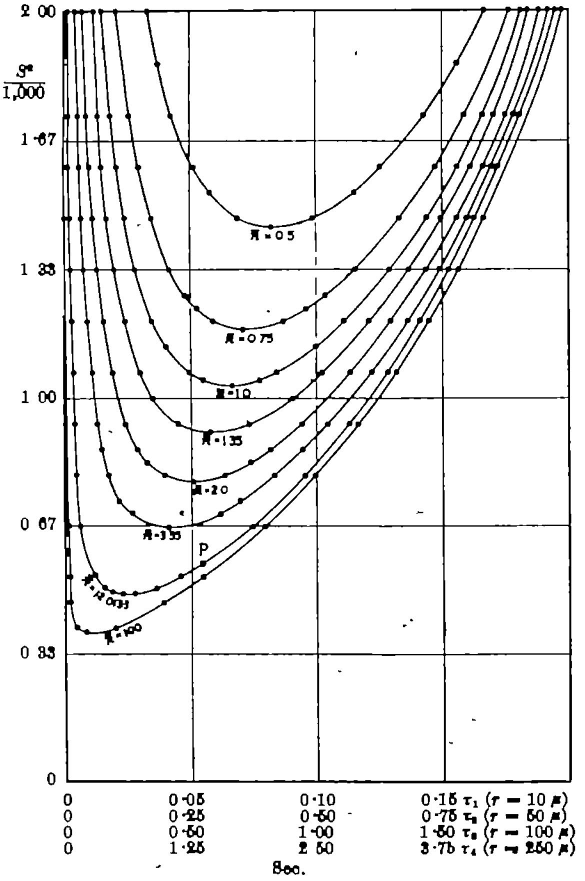
In the probability-after-effect method of measuring the average speed of spermatozoa, a small drop of semen, or semen diluted 1 : 2—1 : 5 with a suitable diluent, is placed on a microscope slide. A coverslip is gently put on top of the drop, which should be of such a size that, after the coverslip is placed on top, the spermatozoa only swim in one plane. This is not difficult to achieve as spermatozoa often tend to swim in one plane when constrained by a coverslip. A cinematograph film is then taken of the suspension, preferably with a phase-contrast microscope. An overall magnification of about 200 is convenient. The camera should run at 4–10 frames/sec. After developing and fixing, the film is projected on to paper on which a circle of known radius $r$ has been drawn; the number of spermatozoa in this circle is then counted on consecutive frames. The circle should be of such a radius that it contains between 10 and 20 spermatozoa. After the counts have been made we have a series of numbers, as in the row labelled $n$ in the accompanying table. The calculation of the average speed of the spermatozoa from these numbers requires no knowledge of mathematics beyond logarithms and the use of standard tables. The average value of these numbers, $\bar{n}$, and the average value of the squares of the differences between consecutive numbers, $\overline{\delta^2}$, are first calculated, as in the table. Suppose that in this experiment the camera speed was 3·7 frames a second, which means that the time interval, $\tau$, between photographs was 0·27 sec.; and that the radius of the circle was 51 μ. The average speed, $\bar{c}$, of the sperm suspension is given by the equation:

$$c = -3\cdot6169\, r/\tau \log_{10}(1 - \overline{\delta^2}/2\bar{n}). \qquad (1)$$

The minus sign in front of the right-hand side of this equation arises because $\log_{10}(1 - \overline{\delta^2}/2\bar{n})$ is negative. Substituting the values obtained above in this equation, we obtain $\bar{c} = 120$ μ/sec., the average speed of the spermatozoa in bull semen diluted 1/4 with Ringer fructose at 37° C.

| | | | | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|
| No., $n$, of sperm in circle | 9 | 10 | 15 | 11 | 12 | 12 | 9 | 10 | 14 | 15 | Sum, 117 |
| Difference, $\delta$, between consecutive numbers | 1 | 5 | 4 | 1 | 0 | 3 | 1 | 4 | 1 | | |
| $\delta^2$ | 1 | 25 | 16 | 1 | 0 | 9 | 1 | 16 | 1 | | Sum, 70 |
| Average value of $n$, $\bar{n} = 117/10 = 11\cdot7$<br>Average value of $\delta^2$, $\overline{\delta^2} = 70/9 = 7\cdot7778$ | | | | | | | | | | | |

To obtain reasonable precision, more counts than ten, a number chosen for purposes of illustration of the method in the table, should be made. When the number of spermatozoa in 75 consecutive circles was counted in a similar experiment, an operation which took $2\frac{1}{4}$ hr., the average speed was found to be 111 μ/sec., with a standard error of 24·5. The actual average speed of the suspension, measured by the slow projection method mentioned above, was 117 μ/sec.



Relationship between $s^2$, the square of the standard error of $\bar{c}$, and $\tau$, the time interval, in seconds, between consecutive sperm counts. The scale of $\tau$ varies according to $r$, the radius of the circle in which sperm counts are made; $\bar{n}$ is the average number of sperm in the circle; $\hat{c}$, the estimate of the average speed of the sperm suspension, is assumed to be 110·5 μ/sec. Number of sperm counts, 75. The point $P$ refers to a 0·27-sec. time-interval between counts, on the $r$ = 50 μ $\tau$ scale

The square of the standard error, $s^2$, is calculated by means of the formula:

$$s^2 \doteqdot \frac{\bar{c}^2}{k\bar{n}(x \ln x)^2}\left\{\frac{\bar{n}(1-x)^2(3+x)}{(1+x)}+x(1-x)\right\}, \quad (2)$$

where $k$ is the number of counts and $x = \exp -(\bar{c}\tau/1{\cdot}5708\,r)$.

Equation (2) shows that $s^2$, which is a measure of the precision of the estimate of the average speed, depends on $k$, the number of frames on which sperm counts are made, $\bar{n}$, the average number of spermatozoa in a count, and $\tau$, the time interval between successive frames. Assuming 75 sperm counts, the variations in $s^2$ with $\tau$, for different values of $\bar{n}$ and $r$, are given in the accompanying figure. These curves are useful for determining experimental conditions. Suppose, for example, that the average speed of spermatozoa is about 110 μ/sec. and that it has been decided to make 75 counts of the number of spermatozoa in circles of radius 50 μ, the number in these circles being about 12. The time interval of 0·27 sec. between photographs will make $s^2 = 567$ ($s$ = 23·8) if $\bar{n} = 12$, which was approximately the value obtained in the experiment mentioned above. The disparity between this value of $s$, 23·8, and the earlier value, 24·5, is explicable but unimportant in this context.

A quantitative method of measuring the average speeds at which spermatozoa swim may be of importance in the investigation of human sterility, in the artificial insemination of livestock, and in academic studies on the physiology and biochemistry of spermatozoa. The method described in this communication is still in its infancy, in the sense that further trials are needed to test its efficacy and the extent to which suspensions of spermatozoa approximate in their behaviour to the model upon which the principle of probability-after-effect is based. A fuller account of the theory and practice of the method will be published in the *Journal of Experimental Biology*.

# LIMITING PRODUCTS IN THE PHOTOLYSIS OF ACETALDEHYDE AT HIGH INTENSITY

By M. A. KHAN, PROF. R. G. W. NORRISH, F.R.S., and DR. G. PORTER

THE study of the photolysis of acetaldehyde[1,2] has led to the conclusion that the primary photochemical change is compounded of two reactions, the relative incidence of which appears to be dependent on wave-length:

$$CH_3CHO + h\nu = CH_4 + CO \qquad (1a)$$

$$CH_3CHO + h\nu = CH_3 + CHO \qquad (1b)$$

Investigation at elevated temperatures has revealed the onset of a chain reaction, the quantum yield rising from a value less than unity at 25° C. to 300 at 300° C., for which Leermakers[1] proposed the following scheme, derived from reaction (1b):

$$CH_3 + CH_3CHO = CH_4 + CH_3CO \qquad (2)$$

$$CHO + CH_3CHO = CO + H_2 + CH_3CO \qquad (3)$$

$$CHO + CH_3CHO = CO + CH_4 + CHO \qquad (4)$$

$$CH_3CO = CH_3 + CO \qquad (5)$$

$$2CH_3 = C_2H_6 \qquad (6)$$

$$CH_3 + CHO = CH_4 + CO \qquad (7)$$

At the lowest temperatures and highest intensities investigated, however, it has been found impossible to detect any ethane at all, even by mass-spectrometric analysis[3], though in the reaction above 100° C. small amounts have recently been observed mass-spectrometrically[4,5].

On this account, and on the basis of further analytical results at temperatures below 100° C., Blacet and Blaedel[6] replaced the chain-ending reaction 6 by a recombination of acetyl radicals, leading to the formation of diacetyl, which was detected in roughly the expected amount. There seems little doubt about the correctness of their conclusions. If, however, a sufficiently high concentration of methyl radicals could be generated by reaction (1b) the incidence of reactions (6) and (7) should predominate over that of reaction (2), since the rates of the former are proportional to the second power of the concentrations of radicals and that of the latter to the first power. There is one other second-order radical reaction resulting in non-condensible products to be considered:

$$2\mathrm{CHO} = 2\mathrm{CO} + \mathrm{H_2}, \qquad (8)$$

which, like the other reactions of formyl, may proceed via hydrogen atoms without affecting the present discussion. At limiting high intensities, when terms involving $I_{\mathrm{abs}}^{-\frac{1}{2}}$ become negligible, reactions (1)–(8) lead to the following expression for the ratios of products formed in unit time:

$$\frac{\mathrm{CH_4}}{\mathrm{C_2H_6}} = \frac{\mathrm{CH_4}}{\mathrm{H_2}} = \frac{2k_a}{k_b} + \frac{k_7}{\sqrt{k_6 k_8}}\left(1 + \frac{k_a}{k_b}\right).$$

We have investigated the photolysis of gaseous acetaldehyde at 20° C. and at intensities of the order of $6 \times 10^{-3}$ $Nh\nu$ cm.$^{-3}$ sec.$^{-1}$, using the full radiation of the gaseous flash discharge[7]. We have found that not only is ethane a major product of the reaction but also that the ratio $(\mathrm{CH_4})/(\mathrm{C_2H_6})$ is independent of intensity. Previous photochemical studies at flash intensities have shown that the rise of temperature resulting from the adiabatic nature of the reaction is of major importance[8,9], and it was therefore first necessary to eliminate this complication. This was done by reducing the energy/flash and by addition of inert gas (carbon dioxide) until further addition had no effect on the products. The accompanying table gives the proportions of gaseous products as a function of relative intensity, obtained by photolysing 60 mm. acetaldehyde in the presence of 480 mm. carbon dioxide.

| Relative intensity | $\frac{\mathrm{CH_4}}{\mathrm{CO}}$ | $\frac{\mathrm{C_2H_6}}{\mathrm{CO}}$ | $\frac{\mathrm{CH_4}}{\mathrm{H_2}}$ | $\frac{\mathrm{CH_4}}{\mathrm{C_2H_6}}$ |
|---|---|---|---|---|
| 1·0 | 0·44 | 0·21 | 1·8 | 2·1 |
| 2·4 | 0·45 | 0·21 | 1·9 | 2·1 |
| 5·0 | 0·45 | 0·20 | 1·9 | 2·2 |
| 23 | 0·50 | 0·22 | 1·7 | 2·3 |
| 40 | 0·47 | 0·20 | 1·6 | 2·3 |
| 69 | 0·45 | 0·21 | 1·5 | 2·1 |

Over a seventy-fold intensity-range, the ratio $\mathrm{CH_4/C_2H_6}$ is constant to ± 5 per cent. As ethane can scarcely arise from any reaction other than (6), it follows that reaction (2) does not occur to any significant extent in the intensity-range investigated. Direct confirmation of the absence of reaction (2) was obtained in the following way. A mixture of diacetyl and acetaldehyde in the ratio 1 : 3 was photolysed in excess carbon dioxide using wave-lengths absorbed by diacetyl alone but at an intensity giving rates of decomposition comparable with the above. The decomposition of diacetyl results in the formation of methyl and acetyl radicals[10], and if reaction (2) occurs, methane will be formed. It was found that the gaseous products were ethane and carbon monoxide exclusively. When the same mixture was decomposed by a conventional mercury arc source, again using radiation absorbed only by diacetyl, methane became the major hydrocarbon product. This confirms that the methane found in the high-intensity experiments with acetaldehyde does not arise from reaction (2), in agreement with our conclusions based on the constancy of product ratios.

Our results lead immediately to the following conclusions about the mechanism of this reaction:

(1) For the full wave-length radiation used, $k_a/k_b \nless 1{\cdot}1$.

(2) Since the minimum possible value of $k_a/k_b$ is zero, it follows that $k_7/\sqrt{k_6 k_8} \nless 2{\cdot}2$. Now it is known that the rate constant of the bimolecular chain termination step in the high-temperature photolysis corresponds to unit collision efficiency[11], and it has been concluded that this refers to reaction (6) or (7). If this is so, it follows that the recombination of methyl radicals occurs with a collision efficiency very near unity, since if the constant measured is $k_7$, both $k_6$ and $k_8$ must be nearly equal to $k_7$, because neither $k_6$ nor $k_8$ can exceed the measured value of unit efficiency.

(3) In view of the large proportion of ethane obtained in these experiments, the total absence of ethane at low intensities must be attributed to reaction (2). In this case the fact that chains are not propagated must be accounted for by the statement that in the low-temperature photolysis of acetaldehyde the rate-determining step is not reaction (2) but the decomposition of the acetyl radical by reaction (5).

# NEGATIVE-ION FORMATION IN GASES OF HIGH DIELECTRIC STRENGTH

By Dr. J. W. WARREN, J. MARRIOTT
and Dr. J. D. CRAGGS
Dept. of Electrical Engineering, University of Liverpool

It is widely known that certain polyatomic molecular gases, for example, sulphur hexafluoride, carbon tetrachloride and $\mathrm{CCl_2F_2}$, possess appreciably higher breakdown voltages than certain common gases, such as oxygen, hydrogen and nitrogen, for a wide range of electrode arrangements, gap-spacings and pressures. In an earlier communication[1], we have mentioned some of the relevant papers, to which the following should be added for data on breakdown voltages: Camilli and Chapman[2] for data on $\mathrm{SF_6}$, $\mathrm{CCl_2F_2}$, $\mathrm{CClF_3}$, $\mathrm{CF_4}$, $\mathrm{CHClF_2}$ and $\mathrm{CHF_3}$; Geballe and Linn[3], $\mathrm{CSF_8}$; Wilson, Simons and Brice[4], $\mathrm{C_3F_8}$, $\mathrm{C_4F_{10}}$ and $\mathrm{C_5F_{12}}$; and Kowalenko[5], HCl, HBr and HI. Burhop, Massey and Watt[6] give dissociation data on $\mathrm{UCl_4}$ and $\mathrm{UF_6}$. The dielectric (breakdown) strengths are those measured at pressures of approximately 1 atmosphere in short gaps, for example, between spheres when the spacing is much less than the sphere diameter, where the electric field is approximately uniform.

The purpose of this communication is to extend the discussion given earlier[1] and to present new experimental results on dissociation processes, notably in sulphur hexafluoride.

It is clear[1] that the formation of negative ions during the breakdown process in a gas will tend to reduce, other things being equal, the value of Townsend's $\alpha$ coefficient (particularly for low $X/p$), as Geballe and Harrison[7] have recently suggested for oxygen, and as Penning[8] had earlier pointed out (see also Massey[9], pp. 66, 103). Penning showed how attachment coefficients could, on certain assumptions, be deduced from $\alpha/p - X/p$ data.

Thus, since $\alpha$ is the predominating single factor governing breakdown, higher dielectric strengths would in general be expected for gases showing appreciable electron attachment. This general argument needs further examination, however, since chlorine has, in the conditions of the first paragraph above, a relative dielectric strength (cf. nitrogen) of about 1·5, while appreciably higher values are known for carbon tetrachloride, 6·3–6·4, and certain other gases[1]. Further, carbon tetrafluoride has a relative dielectric strength of only 1–1·1, whereas sulphur hexafluoride has a value of 2–2·5.

Consider, therefore, the following simplified outline of processes of negative-ion formation by electron impact[9], where $Y$ has a positive electron affinity :

$$\left.\begin{array}{l} XY_n + e \rightarrow XY_{n-1} + Y + e \\ \text{followed by the separate process,} \\ Y + e \rightarrow Y^- \end{array}\right\} \qquad (1)$$

$$XY_n + e \rightarrow XY_n^{-*} \rightarrow XY_{n-1} + Y^- \qquad (2)$$

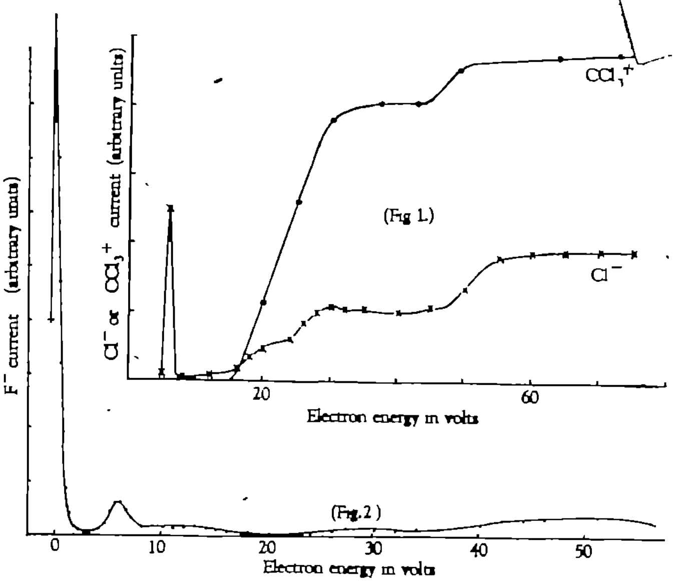
$$XY_n + e \rightarrow XY_n^{-*} \rightarrow XY_n^- \qquad (3)$$

$$XY_n + e \rightarrow XY^+_{n-1} + Y^- + e \qquad (4)$$

Reaction (3) becomes operative at pressures where three-body collisions are probable, whereas (2) is a two-body process. Process (1) doubtless occurs, as Mohr and Weissler[10] indirectly suggest, but the cross-sections would probably be low (Massey[9]) compared with those for processes (2) or (3) and (4). Further, the dielectric strength of chlorine, in which process (1) would be expected to occur at least as strongly as in carbon tetrachloride, is inconsistent with process (1) as the major mechanism. It is also difficult to explain the relative dielectric strengths of carbon tetrafluoride and sulphur hexafluoride on process (1) by itself.

As a preliminary step in the study of electrical breakdown in such gases, we have studied the dissociation patterns due to electron bombardment in a Nier mass-spectrograph source, in $CCl_4$, $CCl_3F$, $CCl_2F_2$, $CClF_3$, $CF_4$, $SF_6$ and in certain other gases. The negative-ion abundances found in the first five of these gases are consistent with the relative dielectric strengths. Figs. 1 and 2 show negative-ion current/electron energy curves for carbon tetrachloride (showing processes (2) and (4) ) and sulphur hexafluoride (process (2) only). The $Cl^-$ curve in Fig. 1 probably rises again near zero electron energy, and $SF_6$ shows large $SF_6^-$ and $SF_5^-$ currents (process (3) ), as first shown by Ahearn and Hannay (to be published). Vought[11] shows a similar curve for $SiCl_3^-$ from silicon tetrachloride. It is likely that the co-existence of processes (2) and (4) would tend to give higher dielectric strengths than process (2), of the same probability, by itself.

The extent to which the low-pressure ($\sim 10^{-3}$ mm. mercury) data on process (2) apply to swarm conditions depends on the probability with which $XY_n^-$ reverts to $XY_n$ (cf. process (3)). This should be unimportant if the electron affinity of $Y$ is greater than the appropriate bond-strength (Massey[9], pp. 47 and 64) ; but space does not permit of a further discussion of this and other related problems.



Variation of negative ion and positive ion currents with electron energy in (1) carbon tetrachloride and (2) in sulphur hexafluoride

Information on the relative importance of processes (2) or (3) and (4) in gaseous breakdown might be obtained by measurements on the dielectric strengths of appropriate mixtures of xenon with sulphur hexafluoride, or with a gas giving processes (2) or (3) and (4), since the ionization potential of xenon is below the critical potential for process (4) in certain of the gases listed above.

The full quantitative testing of the importance of electron-attachment processes in the determination of Townsend's $\alpha$ needs measurement of the basic quantities involved therein[12] together with sparking potential measurements at the same pressures. The quantities are : electron-drift velocity, ionization cross-sections so measured as to include the effect of attachment cross-sections, and the electron energy distribution function[13]. It is thought to be more feasible to evaluate the attachment coefficients from measured values of Townsend's $\alpha$ and to compare them with attachment coefficients measured in the same swarm conditions.

We are greatly indebted to Prof. H. S. W. Massey for advice in the preparation of this communication.

## Staining and Plastic Embedding of Small Mineralized Plant Fossils

Oospores of charophytes are of considerable importance for age determination of freshwater deposits from the Devonian up to the present time. Minuteness and often indistinct sculpture make them difficult objects for study and photographic reproduction, however. During investigations on charophytes from the Triassic of Sweden, some new methods of overcoming these difficulties have been worked out with the assistance of Mr. K. E. Samuelsson, technician of the Palæobotanical Department, Riksmuseum, Stockholm.

The oospores studied are distinctly polar bodies, 0·25–0·50 mm. in length and provided with a faint transverse striation by alternating ridges and furrows. The walls and contents are almost completely calcified; the oospores are therefore semi-translucent and whitish. Observations on sculpture and photographic reproduction are accordingly extremely difficult without previous preparation.

Good results have been obtained by embedding the oospores in plastic after staining them. Plastic has been used for palæobotanical purposes by Leclercq and Discry[1] to elucidate the anatomical structure of larger fossil plants. Two methods were described: in one methyl methacrylate at high pressure and high temperature was used; in the other the object was embedded in a plastic termed 'Marco 26 C' after immersion in alcohol and styrene. A similar method was described by Purves and Martin[2] and was used by Croft[3] for charophyte oospores. The specimens were embedded in 'Marco' resin and ground sections were prepared for studies on the anatomy. When preparing orientated thin sections of various microfossils, Meyer[4], Levinson[5], Emiliani[6] and Kremp and Johst[7] obtained good results with the aid of certain thermoplastics. For the same purpose, Cummings[8] embedded foraminifers in blocks of 'Marco' resin which were cut into smaller pieces, polished, ground down and sectioned.

In the material now studied the oospores were first thoroughly cleaned from fat by immersion in ether. The cleaning is essential because fats lead to irregular distribution of stain; also they may obscure the oospore sculpture, and make the preparation of ground sections difficult by preventing contact between the plastic and the object. Certain specimens were directly stained after cleaning. Generally, the calcite surface is too compact to be stained effectively, however; because of that, the oospores were immersed in a saturated sodium hydroxide solution for some minutes before staining. Etching in a weak solution of acetic acid for a short time also gave good results. After this treatment, the sculpture often revealed a different susceptibility to the dyes used, the furrows becoming deeply stained, the ridges retaining their natural semi-translucent surface. Sometimes, the oospore surface became stained throughout. In some cases, all efforts to stain oospores gave negative results. Hæmatoxylin and methylene blue were found to be the most satisfactory.

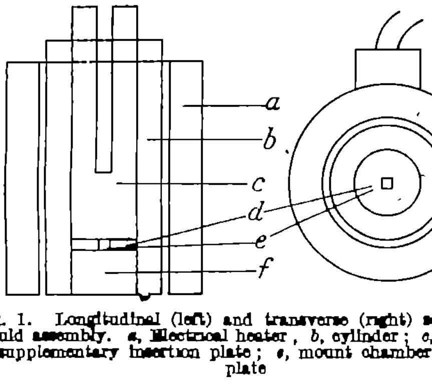

Fig. 1. Longitudinal (left) and transverse (right) sections of mould assembly. *a*, Electrical heater, *b*, cylinder; *c*, plunger; *d*, supplementary insertion plate; *e*, mount chamber; *f*, base plate

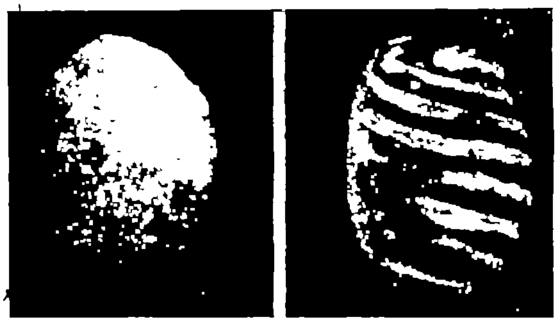

Fig. 2. Oospore of Triassic charophyte not prepared (left), and embedded in polyvinyl chloride after hæmatoxylin staining (right). × 80

For the embedding, an *AB* specimen-mount press equipment (Buehler, Ltd., Chicago) was used. The object is placed on a bed of the plastic powder used (vinyl chloride) on the base-plate of the mould assembly, and covered by plastic powder. The mould assembly is inserted into the press; at a temperature of 120–150° C. and a pressure of 3,500–4,000 lb. polymerization takes place. The specimen is now mounted in a short plastic cylinder, 25 mm. in diameter, and about 10 mm. high. If the polar axis or the equatorial diameter of the oospore has been placed parallel to the upper surface of the cylinder, longitudinal or transverse ground sections can be made according to the usual palæobotanical technique. Due to the toughness of this kind of plastic as compared with the object embedded, ground sections down to 10–15 µ are easily prepared.

It has been observed that the sculpture, when faint, will appear comparatively distinct after embedding. Due to the cylindrical mounting, the oospore can be photographed in two lateral aspects only, or in apical and basal view. Efforts to remove segments of the cylinder followed by polishing of the new surface obtained have been unsatisfactory because of the soft plastic used. Irregularities in the surface and remnants of grinding material pressed into the plastic could not be avoided. For those reasons, an additional part of the mould assembly has been constructed, consisting of a circular insertion plate of the same physical properties as the mould cylinder and closely fitting into the latter. In the middle, the plate has a cubical chamber with sides 7 mm. long. The specimen to be embedded is orientated in the plastic powder to get the polar axis parallel to the upper surface of the cube; pressing and polymerization take place in the usual way. The specimen can be observed and photographed in six aspects, as the highly polished steel walls of the chamber prevent any irregularities in the cube surface.

The oospore can be removed from the plastic by various solvents, among which acetone at a temperature of 50° C. has been found preferable. No damage to specimens has been observed on embedding or dissolution. The plastic cube must not be placed in cold acetone, however, as it makes deep fissures in the plastic and may spoil the oospore. The whole procedure of embedding, polymerization and cooling-down takes about twenty minutes.

One advantage of the method described is that on account of the high light transmission of the plastic the faint sculpture is visible. Further, the difficulty is avoided of handling small strongly polar objects which must be inspected or photographed in a certain view, for example, a needle-shaped specimen from the apex. The method can be used for various small objects, where sculpture is essential and orientation difficult.

## A New Electron Multiplication Process

IF electrons move through a gas in an electric field, their number can increase if they ionize gas molecules by collision—the well-known Townsend avalanche. Recently, it has been shown[1] that in high-frequency electric fields at very low pressures the number of electrons increases, due to the impinging of electrons on the walls of the vessel and the release of secondary electrons. This is a 'wall multiplication' process which can lead to breakdown.

We have investigated the high-frequency breakdown of neon in cylindrical glass vessels with external electrodes. At pressures greater than 50 mm. mercury and frequencies less than, or equal to, $10^7$ c./s., the peak value of the starting field was found to be surprisingly low, corresponding to $X/p = 0\cdot6$ V./cm. per mm. mercury[2]. The energy an electron can acquire is then so small that electron multiplication by collision is negligible. Thus we propose the following mechanism: the first electron which is accelerated by the field will have a much greater number of exciting than ionizing collisions, the more so the lower is $X/p$. Normal excited atoms (emitting resonance quanta within approximately $10^{-8}$ sec.) and metastable atoms will be produced. Only a few of the latter will reach the walls, because they are destroyed by collisions in the gas and also emit resonance quanta. These strike the ends of the vessel either directly or after being absorbed and re-emitted by other atoms. There they release photoelectrons which will be accelerated, etc. We have here what could be termed a 'quantum avalanche), which releases photoelectrons from the wall in increasing numbers.'

In order that an initial electron may be multiplied. it must produce such a number of quanta that more than one electron is released from the wall. Calculations using the meagre data of excitation probabilities[3] and the estimated photoelectric yields[4] make the suggested mechanism likely to occur from $10^7$ to 50 c./s.

After this initial process, once the number of electrons is large, gas ionization can occur by electron collision in stages; that is, fast electrons (> 17 eV.) strike neon atoms to produce excited or metastable atoms, and slow electrons (> 5 eV.) strike metastable atoms to ionize them. With traces of argon a metastable neon atom can ionize an argon atom by a collision of the second kind.

The new avalanche is distinct from multiplication processes in which ionization by electron collision in the gas is accompanied by electron emission at the cathode by ions and quanta, as has been suggested to explain the breakdown of krypton and xenon[5] and recently of atmospheric air and nitrogen[6].

## Crystal Structure of Barium–Strontium–Calcium Triple Carbonate

IT has already been found that calcium carbonate exists in one stable form, β-$CaCO_3$ (calcite), and two unstable forms, λ-$CaCO_3$ (aragonite) and μ-$CaCO_3$ (or vaterite), in the ordinary temperature range. Aragonite is formed if precipitation is carried out at a temperature approaching the boiling point of water (higher than 85° C.), whereas when precipitation is carried out at room temperature only calcite results. The third form of calcium carbonate, μ-$CaCO_3$, is formed by precipitation at 60° C.[1].

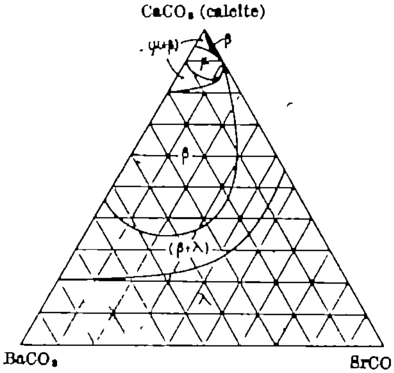

Fig. 1. Co-precipitated at 25–30° C.

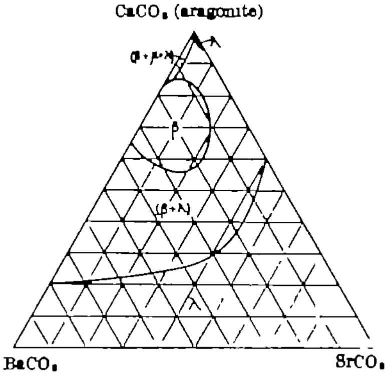

Fig. 2. Co-precipitated at 90–105° C.

Barium carbonate and strontium carbonate have only one stable form (aragonite-type structure) and in both cases temperature of precipitation has no effect on crystal form.

We have co-precipitated the triple carbonate by dropping 1 *N* sodium carbonate solution into a 1 *N* solution of the nitrates of barium, strontium and calcium mixed in the desired proportions and efficiently stirred. These crystalline powders were then examined by an X-ray Geiger counter spectrometer employing copper *K*-radiation.

Figs. 1 and 2 show the variation of crystal structures with molecular composition which we have found at low temperature of precipitation (25° – 30° C.) and at high temperature (90° – 105° C.) respectively. In all, about a hundred and twenty co-precipitated carbonates have been studied, and there have been found three types of solid solutions : aragonite type (λ-carbonate), calcite type (β-carbonate) and vaterite type solid solution (μ-carbonate)[2]. It is noticeable that in the presence of a small amount of isomorphous barium ion, calcium carbonate forms β-carbonate even at a high temperature of precipitation, whereas at low temperature it forms μ-carbonate.

At present no direct correlation between the carbonate structure and the properties of thermionic emission from the BaO–SrO–CaO system obtained by Grey[3] can be offered ; but an investigation of the conversion process of triple carbonate to oxide and other experiments are in progress.

## Activation of Lithium Iodide by Europium

A SINGLE crystal of lithium iodide activated with an impurity of 0·05 mol. per cent europous chloride has been grown from the melt and found to be a relatively efficient scintillator. The crystal is clear and transparent except for a slight non-uniform purple coloration. Under 2537 A. ultra-violet excitation the luminescence is a strong blue very like that of anthracene. A section of the boule was cut and finished with 320-grit abrasive paper into a cylinder of 2 cm. diameter by 1·5 cm. long. The finished crystal was mounted in an atmosphere of dry nitrogen within a polished aluminium reflecting-cup[1] sealed at the open end with a 'Lucite' light-piper and joined to a 5819 photomultiplier.

The luminescence efficiency for γ-rays was found to be 36 per cent that of sodium iodide (with thallium). The decay time constant of the phosphor is 2·0 μsec. The resolution of the photoelectric line in the pulse height spectrum for cæsium-137 γ-rays was observed to be 14 per cent (full width at half maximum).

Fig. 1 is the pulse height spectrum produced by slow neutrons on lithium iodide (with europium). Neutrons obtained from a polonium–beryllium source were moderated in paraffin ; the γ-rays from the source were shielded from the crystal with 3 in. of lead. The spectrum exhibits a resolution of 6 per cent for the 4·785-MeV. products of the $^6$Li(*n*,α)$^3$H reaction.

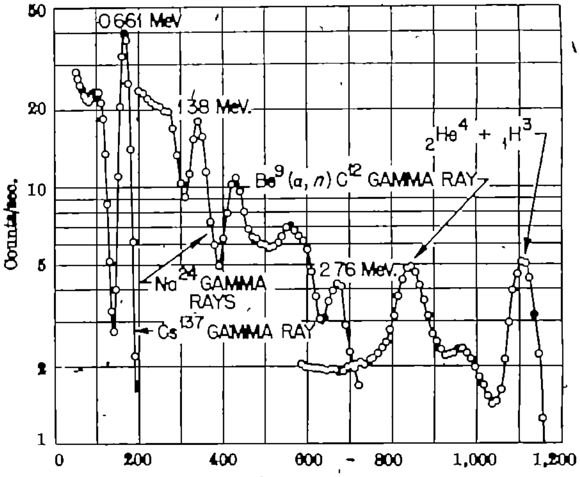

Fig. 1. Pulse height spectrum produced by slow neutrons on lithium iodide (with europium)

Fig. 2 shows the pulse spectra obtained when the crystal was separately irradiated with (*a*) γ-rays from cæsium-137, (*b*) γ-rays from sodium-24, and (*c*) γ-rays and neutrons from a polonium–beryllium source. A partial shield of $B_4C$ was placed between the moderated neutron source and the crystal in order to attenuate the neutron peak so that it would not interfere with the γ-ray peak. The energy calibration was determined from the known values of the sodium-24 γ-rays[2]. A calibrated pulse generator was used to obtain corrections for slight deviations of the apparatus from linearity.

The peak at 843 pulse height divisions (3·40 MeV.) results from the production of electron-positron pairs in the crystal by the γ-rays from the polonium–beryllium source. Previous measurements at this laboratory[3] have indicated a slightly higher value (3·44 MeV.) for this 'pair peak'. The peak at 1,126 divisions (4·55 MeV.) is due to the $^6$Li(*n*,α)$^3$H reaction

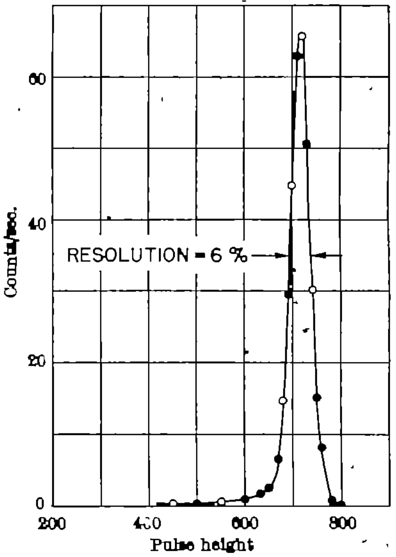

Fig. 2. Spectrum of pulses from lithium iodide (with europium) when exposed to radiations from cæsium-137, sodium-24 and polonium–beryllium neutron source surrounded with paraffin

inside the crystal. Since the $Q$-value of the reaction is 4·785 MeV., it appears that the efficiency of this crystal is somewhat reduced for heavily ionizing particles.

## Measurement of Activated Diffusion of Adsorbed Molecules

IN continuation of a previous study[1] on the contribution of 'surface diffusion' to the transport of adsorbed molecules within porous adsorbents, rates of adsorption of $n$-butane have been measured.

For this purpose, a small metal beam balance was constructed which could be operated under high vacuum conditions. The weighing was performed with movable riders manipulated by means of external controls through ground joints in the enclosing glass tube. The beam was 5 cm. long and fitted with agate knife edges. A sensitivity of $\tan \alpha = 0{\cdot}022$ per 1 mgm. was achieved. The pan carrying the adsorbent was hung on a thin glass rod 30 cm. below the balance and was surrounded by a glass tube inserted in a temperature bath. In the present investigation, an electronically controlled low-temperature thermostat[2] was used with 'dry ice' as refrigerant. Any given temperature in the range from room temperature to − 80° C. could be maintained within ± 0·1° C. for any desired period.

In order to simplify the mathematical treatment of the diffusion problem, rates of adsorption were measured at constant pressures. These were maintained by adsorbing a certain quantity of butane at a convenient temperature, say, 0° C., on an amount of silica gel 100–500 times greater than that of the adsorbent under investigation on the balance.

After proper degassing, the adsorbent was cooled to the desired temperature and the balance system then connected to the constant-pressure device. The increase in weight of the adsorbent (4–125 mgm.) was followed with time, until equilibrium was reached. At − 14° C. this occurred in about three hours, while at the lowest temperature (− 79·5° C.) experimental periods were as long as 30 hr. From a plot of $w_\tau/w_\infty$ versus time ($w_\tau$ and $w_\infty$ are weight increases at time $\tau$ and at equilibrium), overall diffusion coefficients could be evaluated using a solution of the general differential equation of diffusion for a system of finite length and for the particular boundary conditions. The range $w_\tau/w_\infty = 0{\cdot}4$ to $0{\cdot}6$ was chosen to give representative values for the diffusion coefficient.

Rates of adsorption of $n$-butane in porous silica plugs were measured at various temperatures (− 14° to − 80° C.), porosities ($\epsilon = 0{\cdot}72$ to $0{\cdot}53$) and surface coverages ($y/y_m = 0{\cdot}37$ to $6{\cdot}9$, where $y_m$ is monolayer capacity in millimoles/gm.). The plugs (0·3 gm.) were formed by compressing Linde silica (300 m.$^2$/gm.) into small steel cylinders, thus allowing adsorption to occur only through one plane.

In order to demonstrate the feasibility of the above method and to indicate the bearing of surface diffusion on molecular transport in porous media, some of the results obtained may be quoted. For a plug of porosity 0·53 and a surface coverage of $y/y_m = 0{\cdot}9$, the following overall diffusion coefficients were obtained: $7{\cdot}20$, $2{\cdot}33$ and $0{\cdot}64 \times 10^{-6}$ cm.$^2$/sec. at − 14·4°, − 44·2° and − 79·5° respectively. Following Barrer's[3] calculations for the transient state of gas flow into a porous system, these coefficients are corrected for Knudsen streaming. In this way, the corresponding surface diffusion coefficients are obtained: $5{\cdot}04$, $1{\cdot}87$ and $0{\cdot}60 \times 10^{-6}$ cm.$^2$/sec. This indicates that, under the above conditions, 70, 80 and 94 per cent of the total transport is due to the mobility of adsorbed molecules along the surface. From these diffusion coefficients an activation energy of 3,000 cal./mole results, corresponding to 47 per cent of the adsorption energy.

At the lower temperatures, diffusion coefficients vary only slightly with the porosity of the adsorbent, whereas at higher temperatures there is a considerable increase with porosity. In this range the activation energy is also somewhat greater. Diffusion coefficients depend markedly on the surface coverage. For example, at a coverage $y/y_m = 0{\cdot}37$, $\epsilon = 0{\cdot}72$ and $t = -44{\cdot}5°$ C., an overall diffusion coefficient of $4{\cdot}08 \times 10^{-6}$ cm.$^2$/sec. was obtained. This increased steadily with greater coverage and reached a maximum value of $8{\cdot}56 \times 10^{-6}$ cm.$^2$/sec. in the multilayer region at $y/y_m = 3{\cdot}0$, whereafter it decreased.

As a whole, these results are in agreement with those obtained in experiments based on a steady-state flow method, as recently reported by Carman[4].

I wish to thank Dr. P. C. Carman, who made the permeability data necessary for the calculation of the Knudsen streaming available to me. This communication is published with the permission of the South African Council for Scientific and Industrial Research, Pretoria.

## Activity Data and the Association of Hydrogen Chloride in Concentrated Solutions

IN some experiments in which concentrated solutions of hydrochloric acid were employed it was necessary to consider the part played by associated hydrogen chloride in determining its properties. Examination of data on the activity of hydrogen chloride[1] showed that the curve relating mean activity ($a$) to concentration ($c$) was continuous throughout, although its slope increased markedly at about 2 $N$.

Up to 4 $N$ the activity coefficient $\gamma$ is given with reasonable accuracy by the semi-empirical relationship:

$$\log \gamma = \frac{-Ac}{1 + Bc} + Dc + Ec^2 - \log (1 + 0{\cdot}036m) \quad (1)$$

| | 0° C. | | | | 20° C. | | | 50° C. | | |
|---|---|---|---|---|---|---|---|---|---|---|
| $c$ ($N$) | log $\gamma$ obsv. | $'c$ | $10^2 \times K$ | $10^2 \times K^1$ | log $\gamma$ obsv. | $'c$ | $10^2 \times K^1$ | log $\gamma$ obsv. | $'c$ | $10^2 \times K^1$ |
| 5 | 0·44 | 4·5 | 3·20 | 2·5 | 0·39 | 4·4 | 3·1 | 0·30 | 4·4 | 3·2 |
| 6 | 0·59 | 5·4 | 1·38 | 2·1 | 0·52 | 5·2 | 3·0 | 0·42 | 5·3 | 3·0 |
| 7 | 0·74 | 6·1 | 0·79 | 2·4 | 0·66 | 5·9 | 3·2 | 0·53 | 6·0 | 2·8 |
| 8 | 0·89 | 6·8 | 0·44 | 2·6 | 0·79 | 6·6 | 3·2 | 0·65 | 6·7 | 3·0 |
| 9 | 1·03 | 7·4 | 0·15 | 2·9 | 0·93 | 7·3 | 3·2 | 0·76 | 7·2 | 3·5 |
| 10 | 1·17 | 8·0 | 0·14 | 3·1 | 1·05 | 8·0 | 3·1 | 0·87 | 7·8 | 3·6 |
| Mean $K^1$ | | | | 2·6 | | | 3·1 | | | 3·2 |

where $c/m = a_1 - b_1 m$, and $A$, $B$, $D$, $E$, $a_1$ and $b_1$ are constants that have been evaluated by Harned and Owen[2].

Above 4 $N$ the observed values of $\gamma$ are less than would be expected from the above relationship. If deviations are due to association into an ion pair or a truly associated type, the values of the concentration interpolated from the curve relating calculated log $\gamma$ and $c$, using log $\gamma_{\text{obsv.}}$, might be assumed to be the actual concentrations of the free ions.

Fig. 1 shows the curves for log $\gamma$ against $c$ calculated from the above relationship for $c = 4 - 10\,N$ at 0°, 20° and 50° C. The experimental values of log $\gamma$ were then interpolated from these curves to give values of $'c$ corresponding to the free ion concentration (see table).

Consider now the equilibrium :

$$H^+ + Cl^- = HCl$$

$$K = \frac{c - 'c}{'c^2} \cdot \frac{\gamma_{HCl}}{\gamma_{Cl^-} \cdot \gamma_{H^+}} = \frac{c - 'c}{'c^2} \cdot \frac{\gamma_{HCl}}{\gamma^2_{\pm HCl}}, \qquad (2)$$

where $c$ is the total hydrogen chloride concentration.

If this association were of the normal type as understood in the case of acetic acid, then $\gamma_{HCl} \sim$ constant $= 1$ at $c = 0$. However, this assumption leads to values of $K$ that are not constant (see table). Making the further assumption that, as for acetic acid in dilute solution, either $\gamma_{H^+} = \gamma_{Cl^-} = \gamma_{HCl} = 1$, or $\gamma_{HCl} = \gamma^2_{\pm HCl}$, a constant $K^1 = \frac{c - c^1}{'c^2}$ (see table) is obtained. The values of $K^1$ are remarkably constant and show little variation with temperature, indicating that $\Delta S_{\text{ass.HCl}} \approx 0$ and $\Delta F_{\text{ass.HCl}} = \Delta H_{\text{ass.HCl}} = 2 \cdot 1$ k.cal./mole.

According to equation (2), $K/\gamma_{HCl}$ can be calculated from the data in the table ; extrapolation to $c = 0$ gives $K$. Theory[3] and experiment[4] demonstrate a linear relationship between log $\gamma$ and $c$ in dilute solutions. The extrapolation was therefore carried out as shown in Fig. 2[5].

Values of $K$ thus obtained were, within extrapolation error, independent of temperature and had a value $K_{c=0} = 0 \cdot 056$, being in reasonable agreement with the value of $K^1$ ; the corresponding value of $\Delta H_{\text{ass.HCl}} = 1 \cdot 7$ k.cal.

The above calculations seem to indicate the validity of the assumption that $\gamma_{HCl} = 1$ and the alternative relationships $\gamma_{Cl^-} = \gamma_{H^+} = \gamma_{HCl}$, or $\gamma^2_{\pm HCl} = \gamma_{HCl}$.

The figures for $K$ and $K^1$ are in accord with that found for nitric acid by light absorption experiments[5], namely, $K_{c=0} = (5 \pm 1) \times 10^{-2}$. The agreement is to be expected, for these two acids have similar strengths.

Available thermochemical data[6] reveal a considerable fall in the heat of formation of solutions of hydrogen chloride at about 2 $N$, becoming much more marked at 5 $N$ onwards. The data for sodium chloride and sodium hydroxide do not show a similar fall until higher concentrations are reached, indicating that at 5 $N$ the association in solutions of these substances is relatively small. It is possible to calculate $\Delta H_{\text{ass.HCl}}$ in an approximate manner from the equations : $Na^+(5\,N) + H_2O + Cl^-(5\,N) = Na^+(5\,N) + OH^-(5\,N) + HCl(H^+,Cl^-, + HCl_{\text{ass.}} = 5\,N) +$ 15·7 k.cal., and $H_2O = H^+ + OH^- +$ 13·7 k.cal.

If there were no association of the hydrogen chloride, the heats of these reactions should be identical. The difference $\Delta H_{\text{ass.HCl}} = 2 \cdot 0$ k.cal. is in good agreement with the above.

I should like to express my thanks to Sir Eric Rideal for his help and advice. The above forms a part of a research pro-

## Reaction Kinetics of the Cytochrome System

In living wheat roots three cytochromes co-operate, the prosthetic groups of which correspond spectroscopically to the types $a$ (= cytochrome oxidase), $c$ and $b$ of animal preparations. Succinoxidase is the main dehydrogenase system[1]. A factor $X$, characterized by a strong band at 570–575 mμ, is probably linked between succindehydrogenase and cytochrome $b$ [1,2]. Studies of the time-course of oxidation, performed by means of a new automatic spectrophotometric technique[1], show a direct electron transference in the sequence succindehydrogenase $\rightarrow X \rightarrow b \rightarrow c \rightarrow a \rightarrow$ oxygen. The process of oxidation of the reduced cytochromes is a first-order reaction in accordance with the overall formula $Fe^{2+} \rightarrow Fe^{3+} + e$. The molar velocity of oxidation, calculated as $V_e = \frac{1}{\frac{1}{2}t} \cdot c$ ($\frac{1}{2}t$ is time in seconds for the half-way point of oxidation, $c$ is relative molar concentration), shows very similar values for all cytochromes (see table), a fact compatible with a uniform electron transference between the reacting cytochromes, these probably being located in a fairly compact structural unit near the surface of the cells (cf. ref. 1).

At normal anion respiration and 19° C., the cytochromes are predominantly oxidized (64–84 per cent; cf. ref. 1). This means that the electron transference only amounts to a small fraction (c. 1/10 to 1/30) of the full capacity of a nearly reduced system (0–10 per cent oxidation). This damped activity balances the power of reduction of the succindehydrogenase system. The 'over-dimensioned' capacity of the cytochrome system corroborates earlier experiences as to the low oxygen requirement; wheat roots maintain their full anion respiration at an oxygen tension amounting to only 1/10 to 1/20 of normal aeration (cf. ref. 3).

The re-oxidation of a completely reduced cytochrome system (anaerobical conditions) agrees with $\frac{1}{2}t$ = 10–40 sec. It was found that the diffusion of the oxygen from the medium to the respiring cells is not a limiting factor, whereas the continuous delivery of electrons from succindehydrogenase has a general retarding effect. In absence of succindehydrogenase the re-oxidation would be completed in $\frac{1}{2}$–1 sec.

After a rapid shift from aerated to complete anaerobiosis, the cytochrome oxidase is reduced with $\frac{1}{2}t$ = 10 sec. (approx.), or about the same as for re-oxidation. The reduction of $c$ and $b$, however, is

Relative Velocities of Electron Transference ($V_e$) in the Cytochrome System of Living Wheat Roots.
Percentage values in brackets. Relative concentration of $a$, 1; $c$, 2, and $b$, 3·5.

| Cytochrome | $a$ | $c$ | $b$ |
|---|---|---|---|
| Reduction (from aerobic to anaerobic) | 0·090 (100) | 0·032 (35) | 0·011 (12) |
| Re-oxidation (from anaerobic to aerobic) | 0·100 (100) | 0·100 (100) | 0·095 (95) |

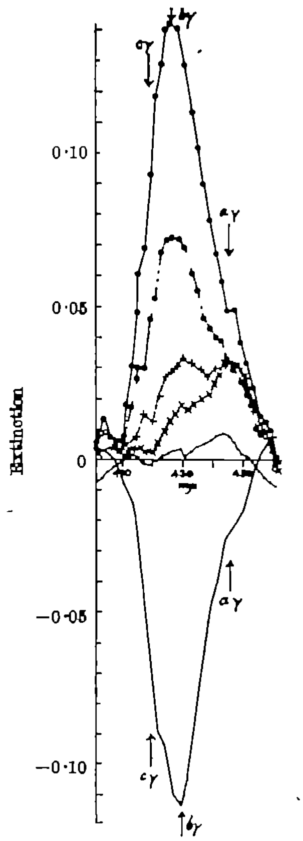

Fig 1. Oxidation–reduction curves ($e$ red.–$e$ ox.; cf. ref. 1) of a 15-mm. thick bundle of wheat roots, exposed to increasing anaerobiosis (oxygen-free succinate) and thereafter re-oxidized. The positive curves illustrate the increasing reduction: ·— after 1 min., ×—× after 4 min., +—+ after 7 min., ○—○ after 18 min., and ●—● after 32 min. The negative curve shows the rapid re-oxidation 1 min. after shifting over to aerated solution. Absorption spectrum automatically recorded in intervals of 2 mμ (cf. ref. 1). The very rapid response of the cytochrome oxidase is clearly shown

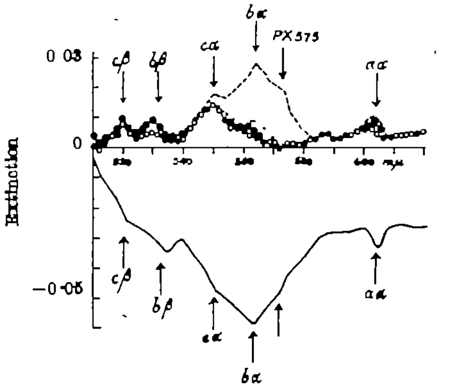

Fig. 2. As in Fig. 1, but comprising the α- and β-bands of the cytochromes. Upper curves, reduction in oxygen-free succinate: ○—○ after 1 min., ●—● after 6 min., - - - - after 16 min., and —·—·— after 32 min. The time order $a > c > b > PX$ 575 is clearly shown. Lower curve shows the re-oxidation in aerated solution

considerably retarded (see table), the molar quantities of these enzymes amounting to five to six times that of *a*. The retarded reduction reflects the much slower rate of the succindehydrogenase system, namely, of the dehydrogenation of the succinate, as compared with the full capacity of the electron transference in the system $X \rightarrow b \rightarrow c \rightarrow a \rightarrow$ oxygen. At re-oxidation the reaction starts with a turnover number of more than 20,000 per min. (which is 10 to 30 times the 'normal' turnover number of about 1,700; cf. ref. 1), whereas at reduction the reaction starts with the moderate speed of the succindehydrogenase system, resulting in the observed retardation of cytochrome *b* with a factor of 9 or 10. The rapid response of the cytochrome oxidase at reduction, on the other hand, reflects the higher velocity of the electron transference, *a* being immediately reduced by *c* and *b*. As previously stated[1] the potential states of *c* and *b* are not so far apart as those of *c* and *a*, as a consequence of which a reversible equilibrium exists between *c* and *b* (and between *b* and the factor *X*).

The interpretation given here of the retarded reduction of the cytochromes *c* and *b* does not support the deductions advanced by Chance as to *b* not lying in the direct path of electron transference from succinoxidase to oxygen[4]. The tissue preparations used by him are obviously less suited for a clear-cut study of the reaction kinetics of the cytochrome system, because the interaction with the systems supplying the succindehydrogenase is broken. It is known that an accumulation of fumarate may reverse the stream of electrons from succindehydrogenase to *b* (and *c*) and completely stop the reduction.

## Relative Specificity of the Chemically Modified 'Aspergillus niger β-Glucosidase'

The work of Miwa and co-workers[1,2] showed that the relative specificity of β-glucosidase, expressed in terms of the ratio of enzyme activity toward β-glucosides with different aglucons, differs over a wide range depending on the source of the enzyme preparations. These differences are considered to be due to the difference in the structure of enzyme proteins themselves rather than contaminating substances, since they remain almost unchanged upon fractionation of enzyme preparations as well as with preparations of different purity.

In immunochemistry it is well known that the specificity of antigenic proteins can be artificially altered by modifying their chemical structure in various ways. In view of this, it seemed interesting to examine whether or not we are able to modify the relative specificity of the enzyme by chemical means. Such a study might give a clue to the elucidation of the structure of enzyme proteins responsible for relative specificity.

In the present work, β-glucosidase from *Aspergillus niger* was used. This enzyme has been considerably purified in Miwa's laboratory and shown to be a protein with nitrogen content of 15·4 per cent[3]. As chemical reagents capable of modifying the structure of enzyme protein, formalin and nitrous acid were employed.

*Enzyme preparation*. The method of procedure was similar to that applied by Niwa[3]. Specific activity *f* (phenyl-β-glucoside) was about 25 in glycine–hydrochloric acid buffer of *p*H 3 and 10 in citrate. Niwa carried purification further, but in the present work chemical treatment was carried out with this enzyme preparation redissolved in the concentration of about 2 per cent.

*Treatment with nitrous acid*. (*a*) One part of 30 per cent sodium nitrite and 0·2 part of glacial acetic acid were added to four parts of enzyme solution. After keeping in a refrigerator for 48 hr. the enzyme was precipitated, washed with acetone and dried *in vacuo* over calcium chloride. A yellow powder was obtained. (*b*) To 10 ml. of a 2 per cent solution of the yellow enzyme powder a small amount of α-naphthylamine was added and kept at 30° C. for 2 hr. The enzyme was precipitated and washed with acetone and dried *in vacuo*. The resulting preparation was red.

*Treatment with formalin*. (*a*) To seven parts of enzyme solution one part of 30 per cent formalin was added and allowed to stand at 30° C. for 48 hr. Then the enzyme was precipitated with acetone, washed free from formalin and dried *in vacuo*. (*b*) The same procedure as (*a*) was used, except that the ratio of enzyme solution and formalin was 4 : 1 and the duration of incubation was 70 hr. (*c*) The same procedure as (*b*) with incubation of 144 hr.

The accompanying table shows the results thus obtained. It will be seen that relative specificity is affected by the action of nitrous acid or formalin. Changes of the relative specificity of the enzyme treated with nitrous acid are recognizable in *p*-nitrophenyl-, *p*-cresyl- and methyl-β-D-glucosides. This modification of the relative specificity in *p*-nitrophenyl-β-D-glucoside is nearly restored to the original value after treatment with nitrous acid followed by coupling with α-naphthylamine. On the other hand, it has long been postulated that nitrous acid forms nitroso or diazo compounds with protein in addition to deaminizing[4]. Thus, it may be suggested that the modification of the relative specificity is due to the

RELATIVE SPECIFICITY OF CHEMICALLY MODIFIED '*Aspergillus niger* β-GLUCOSIDASE'

| Substrate: β-D-glucoside of | Original enzyme | Treatment with nitrous acid |  | Treatment with formalin |  |  |

* Specific activity *f* was calculated from $f = K/g \log 2$, where $K$ is a velocity constant of the first-order reaction and $g$ is grams of enzyme in 8 ml. of reaction mixture composed of buffer (*M*/5 citrate, *p*H 3·0), substrate (0·048 *M*) and enzyme solution in the ratio of 1 : 1 : 2. Temperature, 30° C. Phenyl-β-D-glucoside is used as standard substrate for determining β-glucosidase activity.

† The rate of hydrolysis of the phenyl-β-D-glucoside is taken as unity.

change of enzyme structure. On testing formolized enzyme, it is found that the hydrolytic activity against salicin is specifically decreased. Moreover, the relative specificity is affected in the same way and to the same extent with formalin for two, three and six days respectively. These results indicate that chemical reaction is completed at least within two days under these conditions. From the point of view of species specificity of the enzyme, it should be noted that '*Aspergillus niger* β-glucosidase' is resistant to formalin, whereas almond emulsin is very sensitive[5,6]. The reaction of protein with formalin is more complicated than simply the formation of methylene compounds. In any event, free amino groups are blocked in addition to changes in other groups such as indole nuclei and imidazol rings. In the hydrolysis of *n*-alkyl-β-D-glucosides, nearly all the β-glucosidases from different sources exhibit an increase in the ease of hydrolysis with increasing chain-length except in the case of *Aspergillus niger* β-glucosidase[6,7]. In this respect it is significant that, after treatment with nitrous acid or formalin, *Aspergillus niger* β-glucosidase also shows a small increase with increasing chain-length.

There still remains, however, the question whether or not we are able to change greatly the enzymatic properties without losing its activity.

I wish to thank Prof. Tomoo Miwa, of Tokyo Bunrika University, in whose laboratory this work was carried out, for his help and encouragement throughout this investigation.

## Fate of Sodium 2,4-Dichloro-phenoxy-ethyl-sulphate in the Soil

SOME additional aspects of the "Fate of Sodium 2,4-Dichloro-phenoxy-ethyl-sulphate" which Prof. L. J. Audus has discussed[1] may possibly lend further understanding to this interesting problem.

Research on sodium 2-(2,4-dichloro-phenoxy)ethyl-sulphate for the past three years in this laboratory has indicated that the compound is readily hydrolysed under acid conditions to 2-(2,4-dichloro-phenoxy)-ethanol and sodium acid sulphate[2]. It has also been found that the soil organism, *Bacillus cereus* var. *mycoides* (Flugge) Smith, Gordon and Clark, possesses enzymes which can catalyse this hydrolysis[3,4]. The enzymatic conversion occurs in soil as well as *in vitro*[4].

An important point for consideration is the fact that 2-(2,4-dichloro-phenoxy)ethanol, which is quantitatively generated when sodium 2-(2,4-dichloro-phenoxy)ethyl-sulphate is added to soil[4], is a highly potent root growth inhibitor. It is extremely difficult to distinguish between 2,4-D and 2-(2,4-dichloro-phenoxy)ethanol on the basis of root growth suppression.

Although 2-(2,4-dichloro-phenoxy)ethanol can be oxidized to 2,4-D in soil[4], it is yet impossible to ascribe the herbicidal action of sodium 2-(2,4-di-chloro-phenoxyl)ethyl-sulphate exclusively to one or the other of these compounds. Under field conditions it is most likely that when sodium 2-(2,4-dichloro-phenoxy)ethyl-sulphate is added to soil, the hydrolysis product 2-(2,4-dichloro-phenoxy)ethanol, as well as any 2,4-D which is generated, can suppress the root development of weed seedlings.

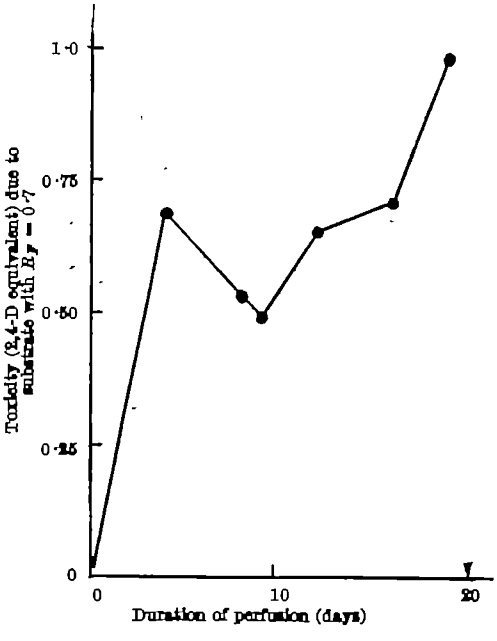
[4] Vlitos, A. J., *Contrib. Boyce Thompson Inst.*, 17 (in the press).

THE possibility that phytotoxicity generated when sodium 2,4-dichloro-phenoxy-ethyl-sulphate is perfused through soil might be due to hydrolysis to a toxic 2,4-dichloro-phenoxy-ethanol has been seriously considered; but I have so far been unable to obtain any evidence that this compound accumulates in the perfusate. The toxicity seems to be due entirely to 2,4-D. Four independent reasons for this conclusion are given in the original paper[1]. The most convincing evidence comes from assays using paper chromatography to separate the toxic compounds in any possible mixture[2]. Only one compound has, as yet, been found in this very sensitive assay, which will detect $10^{-4}$ γ equivalents of 2,4-D, and this has an $R_F$ value (0·7) identical with that of 2,4-D. A graph showing toxicity changes due to this compound in the perfusate is reproduced herewith. It is extremely unlikely that the ethanol has the same $R_F$ value (solvent: butanol–ammonia) as the 2,4-D, but it has not been possible as yet to check this experimentally. The most rational explanation of the results to date is that the hydrolysis of sulphate to ethanol



is the limiting reaction in the soil and that the shape of the toxicity–time curve is a direct reflexion of the activity of the hydrolysing organism. The further conversion to acid, probably by a different organism, takes place so rapidly that the ethanol intermediate can never accumulate in amounts detectable even by the sensitive assay employed.

## Effect of Cortisone on Tissue Potentials in Man

SINCE a study[1] of the changes produced by cortisone in the decolorization times of oxidation-reduction dyes injected in the skin gave some grounds for believing that this drug caused a change in the electrode potential ($E_h$) of the tissues, it seemed desirable to test the hypothesis by direct electrical measurement. The results show that a change in potential does occur, and the method employed offers a simple clinical means of investigating the peripheral action of cortisone and other substances.

A platinum–iridium needle insulated to within a few millimetres of the tip forms the electrode, which is inserted subcutaneously and connected to one arm of an electrometer-type of potentiometer. The other arm of the potentiometer is connected to a calomel half-cell which is dipped in a beaker of saturated potassium chloride solution; the patient places one finger into the same beaker to complete electrical contact with the skin. The potential difference was found to rise slowly during the period following insertion of the needle, so that for purposes of comparison readings should be made at corresponding times, measured from the moment of insertion. Preliminary investigation showed the errors due to the variables of temperature and body resistance to be negligible.

In a first experiment, two patients were studied over a ten-day period during which cortisone was given intramuscularly in divided doses to a total dosage of 600 mgm. in the three-day period covered by the fifth, sixth and seventh days. On each of the ten days the electrode potential of the subcutaneous tissues was measured in the fasting patient at the same time in the early morning, using three separate sites of needle-electrode insertion. The mean of the potentials for the first four and last two days of the trial was then compared with the mean for the second and third days of the cortisone period. There was a significant fall of potential in both cases.

Case 1. Mean fall = 25 mV. ($n = 23$, $t = 5.4$, $P < 0.001$)
Case 2. Mean fall = 21 mV. ($n = 23$, $t = 4.4$, $P < 0.001$)

In a second experiment, five patients were given cortisone acetate orally in a single dose varying from 125 to 500 mgm., and in every case there was a significant fall of potential during the second hour after administration. The fall ranged between 17 and 23 mV.; $P$ was less than 0·01 in four cases and less than 0·001 in the other case. In a control experiment using the aqueous vehicle in which cortisone acetate is suspended, no significant change was observed.

The fall in electrode potential of the subcutaneous tissues observed by this method is not specific to cortisone, as we have measured a fall after the intravenous administration of both ascorbic acid and glutathione. In fact, the effect of 1 gm. ascorbic acid given by this route may be observed leaving the needle *in situ*, since it is apparent within two minutes of the injection. Our experiences with indicator dyes, together with the observations of Long *et al.*[2] on the effect of cortisone and ascorbic acid on tuberculin sensitivity in guinea pigs, had originally led us to expect that cortisone, by shifting the ascorbic ⇌ dehydroascorbic acid equilibrium in the tissues to the right, would produce a rise in tissue electrode potential. In fact, a fall has been found uniformly to occur. This is in harmony with the work of Stewart *et al.*[3], who have shown that 20 per cent of the plasma ascorbic acid is normally in the dehydro form and that cortisone causes the temporary disappearance of this oxidized fraction without altering the total level. This shift of the equilibrium to the left is consonant with a fall in electrode potential as found in our experiments, and occurred at the same time after oral administration of the drug.

We wish to thank Dr. George Brownlee for advice and criticism; the Cambridge Instrument Co., Ltd., for making the needle electrode to our instructions; the Medical Research Council and Ciba (Basle) for supplies of cortisone and control material; and British Drug Houses, Ltd., for the glutathione.

## Diabetogenic Effect of Nucleic Acid

THE discovery of alloxan diabetes was followed by an examination of the specificity of alloxan. Whether alloxan could be found in biological material and its possible function in the intermediary metabolism were also investigated.

The effect of substances natural to the organism obviously attracted attention. Griffiths[1] found that chronic hyperglycaemia in rabbits could be induced by sufficient doses of uric acid, provided the rabbits lived on a diet lacking cysteine and methionine for a long period. He found that a dose of 1 gm. of uric acid to 1 kgm. body-weight was sufficient. The investigations of J. W. Patterson[2] on the diabetogenic effect of dehydroascorbic and dehydroisoascorbic acids are also of importance.

Nucleic acids as a group are related to uric acid. We have examined whether nucleic acids could have diabetogenic effects under certain conditions.

Ribonucleic acid (Natrium nucleinicum e faece Merck), 1 gm. to 1 kgm. body-weight, dissolved in water was injected intraperitoneally into three rabbits starved for 48 hr. The curve of blood sugar immediately after the injection of nucleic acid was followed by the determination of glucose by Hagedorn–Jensen's method. Then for ten days the urine was collected from metabolic cages and we determined glycosuria at intervals of 24 hr.

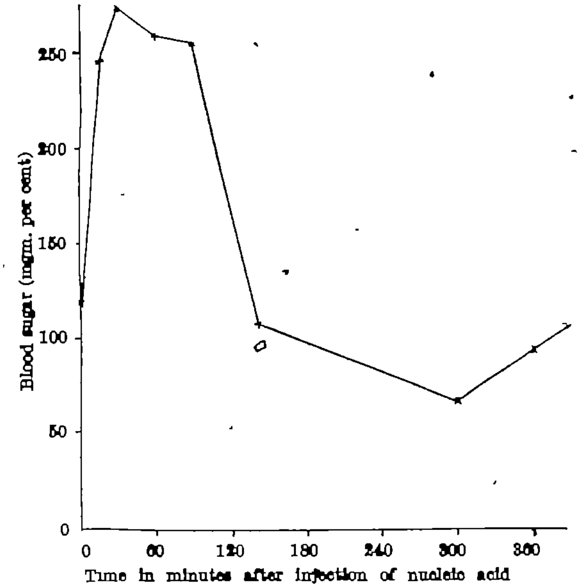

Fig. 1

Nucleic acid was injected in the same doses as in the previous experiment to a group of rats starved for 24 hr. Then the rats were killed at different intervals (30 min., 45 min., 90 min., and 300 min.) after the injection. Immediately after death, we removed some of their organs and determined quantitatively the reduced glutathione in them, employing the modified Kühnau method. Results from this experiment, reproduced in Fig. 2, have been arrived at statistically.

The intraperitoneal injections cause hyperglycaemia in rabbits; later, hyperglycaemia changes into hypoglycaemia, and finally the blood sugar content remains at the level of about 200 mgm. per cent (Fig. 1). Then the rabbits show slight glycosuria for a few days.

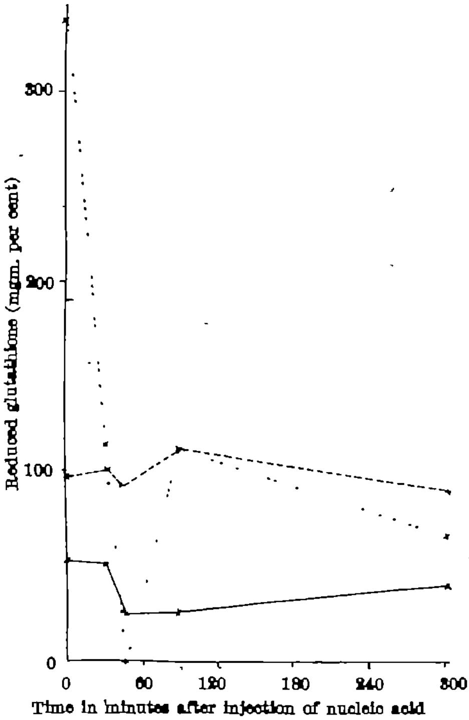

Fig. 2

– – – – –, Liver; . . . . ., adrenals; ————, pancreas

If animals which have lived on a diet lacking cysteine and methionine for several days are used, the symptoms of diabetes are much stronger.

The curve of the contents of reduced glutathione in the livers, pancreas and adrenals is shown in Fig. 2. The courses of the curves are identical with those observed after the injection of alloxan[3].

## Seasonal Variation in the Plankton and Salinity of the Hauraki Gulf, New Zealand

THE seasonal variation of the plankton of the Hauraki Gulf, New Zealand, has not previously been studied. From November 1948 until October 1950, a pilot survey of the plankton of the Gulf was made possible by the courtesy of the Marine Department of the Government of New Zealand, which made available its research vessel *Ikatere*.

It is found that there is an inner coastal population of fairly constant composition, characterized by *Corycaeus aucklandicus* Krämer, and containing also *Temora turbinata* Dana, *Acartia clausii* Giesbrecht and *Euterpina acutifrons* (Dana), all of which are quite common. In summer months only, *Penilia avirostris* Dana[1], *Podon polyphemoides* Leuchart and *Evadne* species are also found in quantity in the coastal population.

The outer region of the Gulf contains an oceanic population which varies according to the season. From November 1948 to April 1949, from October 1949 to May 1950, and in October 1950, the outer region of the Gulf was dominated by salps. These were chiefly *Thalia democratica* (Forskål), but *Salpa fusiformis* Cuvier and *S. cylindrica* Cuvier were also common on occasion. Associated with the salps were the copepods *Rhincalanus cornutus* Dana and *Sapphirina* species, and also stomatopod larvæ.

In the winter months, particularly July, of 1949 and 1950, the oceanic region of the Gulf was dominated by chætognaths, notably *Sagitta planctonis* Steinhaus, *S. serratodentata* Krohn and *S. hexaptera* d'Orbigny. With these the copepod *Oncaea venusta* Philippi was frequently taken.

During July and August 1949, and in July 1950, salps were not recorded at all in the Gulf. In August 1950, they were very infrequent. In view of the known life-history of salps, it is clear that the body of water containing salps in summer cannot be the same as the body of water containing chætognaths in winter. Two other possibilities exist. Either there is a constant invasion of oceanic water from the same source, bearing salps in summer and sagittas in winter; or two distinct oceanic waters invade the Gulf alternately, in summer a salp-bearing water from one source and in winter a sagitta-bearing water from another source.

It is not possible to correlate the occurrence of salps with temperature. Each year salps reappeared in the coldest months—August or September—with a water temperature of 13°–14° C. They persisted through the summer with maximal temperatures of 22° C., and then disappeared in July when the temperature had dropped to 15° C.

In the second year of the survey, salinity observations were made to discover whether the seasonal changes in plankton could be correlated with changes in salinity. It was found that the average salinity of the Gulf rises from 35·30 parts per thousand in November, when salps are dominant, to 35·70 in July, when salps are absent. Salinity then declines to 35·50 parts per thousand in August, when salps are found infrequently, and then to 35·40 in October, when salps are dominant. It will be noted that salps reappear when salinity begins to decrease. Conversely, chætognaths are almost entirely restricted to the months April–August, when salinities are above 35·50.

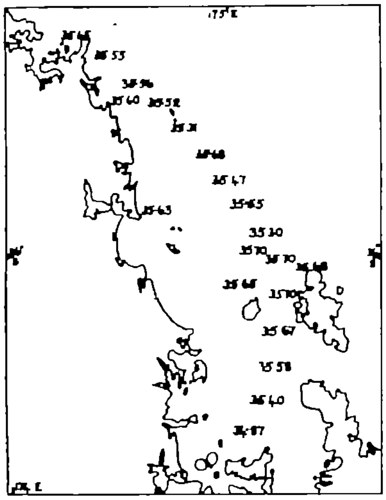

**Fig. 1.** Salinity (parts per thousand) of the Hauraki Gulf and more northern waters in July 1950

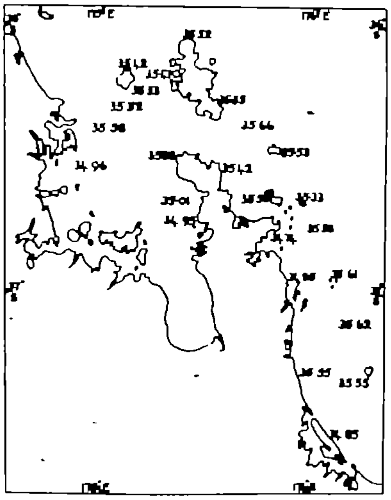

**Fig. 2.** Salinity (parts per thousand) of the Hauraki Gulf and more eastern waters in August 1950

When the salinity of the Gulf is rising, the water of high salinity apparently comes from the north. In July, the bulk of the water in the Gulf is of salinity 35·60–35·70, but there is an outer area of salinity about 35·50 (Fig. 1). In August the Gulf appears to have been diluted from its outer limits inwards (Fig. 2).

These results, by themselves, are not incompatible with either type of oceanic influx suggested above. It is believed, however, that the Notonectian Current from the Tasman Sea varies in its flow around the North Cape of New Zealand, being greatest in summer and least in winter[2]. So it appears possible that the seasonal variation of plankton and salinity described above may be associated with variation in the flow of this current; but this is, of course, not proved.

The observations on which this report is based were made when I was a temporary lecturer at Auckland University College. I am indebted to Prof. W. R. McGregor and the Council of that College for extending the tenure of my appointment so that the survey could be operated over two years.

## Phosphate Content of Mudbanks along the Malabar Coast

The importance of the phosphate content of water masses as a limiting factor in their organic productivity has long been recognized. The investigations of Mortimer[1], Moore[2], Stephenson[3] and Rochford[4] have stressed the importance of the bottom muds in the phosphate cycle.

The inshore sea along the Malabar coast of India has a peculiar environment owing to the formation of extensive banks of very fine mud settling regularly after the rough weather of the south-west monsoon which occurs from the month of June to the beginning of September. The area is also subject to a heavy rainfall (121 in. per annum at Calicut) most of which occurs during these months. This region of the Indian coast is highly productive in respect of fisheries and shows a marked seasonal cycle in its biological features, this being apparently closely related to the south-west monsoon.

In connexion with the study of the fishery and ecology of the inshore area near Calicut, it was considered useful to study the composition of the material forming these mudbanks and to follow the seasonal changes, especially in its phosphate content in relation to the phosphate content of the overlying water and to the seasonal changes in the biology of the area. In view of recent trends in such phosphate studies, it was particularly suggested to me by Dr. N. K. Panikkar that the west coast mudbanks probably form reservoirs of inorganic nutriment playing an important part in the annual cycle, and that their detailed investigation is necessary to understand the fisheries cycles. Work on these lines is in progress, and it is already apparent that these mudbanks contain considerable quantities of phosphates (even if we take only the interstitial inorganic fraction into account) and that the results confirm the above view. The work has also shown that the release of phosphates from the mudbanks takes place largely during the south-west monsoon period, when the waters are continually highly agitated by the strong winds.

The accompanying table shows the values of interstitial and adsorbed phosphates of mud samples taken at two stations near Calicut during the months of January–June 1952. The procedure followed in these estimations was that detailed by Rochford[4] with slight modifications. The mud samples were taken by means of a grab sampler instead of a core sampler.

The individual values of the interstitial phosphate (per gm. of mud) were themselves often higher than the corresponding values of inorganic phosphate (per litre) in the overlying water during the pre-monsoon months, and per unit weight or volume the mud may be said to contain several hundred times as much phosphate as the water-layer above it. The interstitial phosphate is released into the water by agitation. A severe agitation of the sea bottom, noticed during the south-west monsoon of 1950, resulted in a large increase in the phosphate content of the water. During

INTERSTITIAL PHOSPHATE AS PHOSPHATE PHOSPHORUS IN PARTS PER MILLION OF DRY MUD AND ADSORBED PHOSPHATE SIMILARLY IN DRY SILT FROM MUD SAMPLES NEAR CALICUT

| Months | Samples per station | Station I (4 m.) | | | | Station II (19 m.) | | | |
|---|---|---|---|---|---|---|---|---|---|
| | | Interstitial | | Adsorbed | | Interstitial | | Adsorbed | |
| | | Range | Mean | Range | Mean | Range | Mean | Range | Mean |
| January | 5 | 13 to 35 | 26 | 19 to 80 | 47 | 21 to 27 | 25 | 18 to 68 | 33 |
| February | 4 | 22 to 43 | 35 | 9 to 41 | 21 | 25 to 33 | 29 | 9 to 22 | 16 |

| April | 4 | 11 to 25 | 17 | 17 to 28 | 24 | 12 to 19 | 15 | 9 to 33 | 18 |
| May | 3 | 13 to 19 | 15 | 20 to 35 | 27 | 24 to 46 | 33 | 12 to 17 | 14 |
| June | 2 | 7 to 20 | 18 | 22 to 25 | 23 | 9 | 9 | 4 to 10 | 10 |

the pre-monsoon months in 1952 again, the phosphate content of the inshore water was very low, but it increased after the commencement of the monsoon rough weather that disturbed the mudbanks. It appears highly probable that the well-marked seasonal features in the biology of the inshore area along this coast are closely related among other factors to the existence of these extensive mudbanks, the retention by them of relatively large quantities of phosphates (and perhaps other nutrients) and the release of these during the south-west monsoon every year.

The mudbanks have also been found to contain fairly high quantities of adsorbed phosphate. The material of these mudbanks is derived partly from the laterite formation which fringes this coast[5]. An analysis of a sample of laterite has revealed a high 'adsorbed' phosphate content, and since a considerable quantity of laterite silt is washed into the sea during the rainy seasons, this seems to be a constant source to supplement the local turnover of phosphates in the inshore area.

I wish to thank Dr. N. K. Panikkar, Dr. W. R. G. Atkins and Dr. B. S. Bhimachar for helpful criticism.

## Occurrence of *Puccinia polysora* Underw. in East Africa

Rhind, Waterston and Deighton reported epidemics of *Puccinia polysora* Underw. in West Africa in 1949 and the following years[1]. Fears were expressed that this disease might eventually reach East Africa. Plans were accordingly made for authorities in West Africa to test East African varieties of maize for susceptibility to the fungus, and for the introduction of maize varieties from Central America in the hope that resistant types might be found in an area where the disease is endemic.

The maize rust hitherto recorded in East Africa and generally present throughout the Territories is *Puccinia sorghi* Schw. In June 1952, outbreaks of maize rust, exceeding in severity any previous occurrence, appeared in the Coast Province of Kenya. Collections, which comprised the uredo and teleuto stages, were examined by Dr. G. R. Bisby[2], who stated that the teleuto stage agreed exactly with the original American collections, thus affording final confirmation of an identification which remained uncertain so long as the uredo spores alone were available. This is believed to be the first record of the teleuto stage of *P. polysora* outside America.

Subsequent collections of uredo material were examined from Zanzibar and milder attacks from Uganda and Tanganyika, where both species of rust were found occupying the same leaf. All collections from the Kenya Highland have, so far, been *P. sorghi*; and, in fact, all records of severe attacks of *P. polysora* have been from the warmer, more humid areas. It is hoped that the Kenya Highlands, where maize is the most important food crop of the native population, may remain free.

## *Cerastium arcticum* Lange

RECENT publications containing references to this plant have used the name *C. edmondstonii* (Wats.) Murb. and Ost.[1] in preference to the older name *C. arcticum* Lange[2]. The objection to using the older name is, according to Hylander[3], that "there is no authentic, i.e. chosen by Lange, type specimen". But this in itself is no reason for dismissing the older name since the description is validly published. Moreover, Murbeck and Osterfeld in their description[1] only redescribed Lange's plant. They also took the varietal epithet, var. *edmondstonii*, and gave it specific rank. This is in contradiction to the rules of botanical nomenclature, and therefore the name *C. edmondstonii* is illegitimate.

Recent work on the cytology of this species, using material collected from Snowdon in Wales and Ben Nevis in Scotland, has shown that the chromosome number is $2n = 108$ (Fig. 1). Some seedlings, however, gave higher chromosome numbers, and it is suspected that occasionally this species may be cross-pollinated by *C. holosteoides* Fries (*C. vulgatum* L.), $2n = 144$, which grows in the vicinity. One plant, from Snowdon, showed a highly irregular meiosis with many lagging chromosomes at both first and second anaphase, and it is thought that this may have been a hybrid, although it closely resembled *C. arcticum*. Pollen-mother cells from other plants showed a perfectly regular meiosis with $n = 54$. At first metaphase many multivalents can be seen (Fig. 2), usually in the centre of the cell with the bivalents arranged in a ring outside them. A very similar arrangement has been seen in *C. holosteoides*.

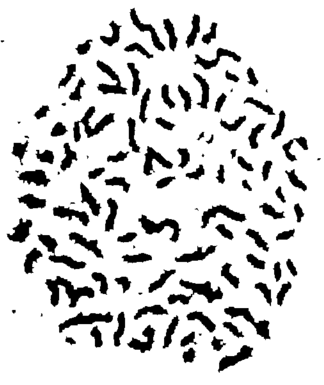

Fig. 1. Root-tip metaphase in *Cerastium arcticum* Lange with 108 chromosomes. × 2,000

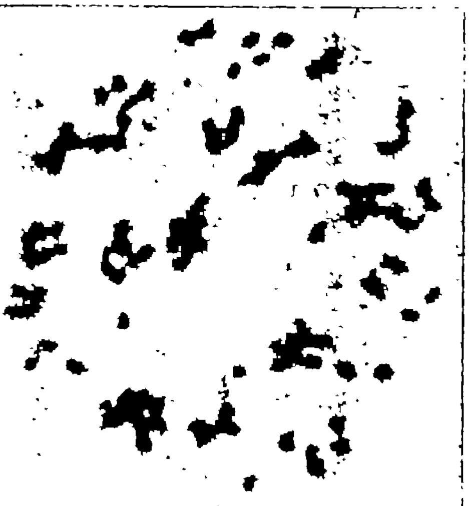

Fig. 2. First metaphase in a pollen mother cell of *Cerastium arcticum* Lange showing many multivalents. × 2,000

Chromosome counts for all the British species of *Cerastium* have now been made. Unpublished counts besides *C. arcticum* $2n = 108$ are *C. cerastoides* (L.) Britton $2n = 38$ and *C. pumilum* Curt. $2n = 90$ and $2n = 95$. The count for *C. cerastoides*, which was also collected on Ben Nevis, agrees with counts made by other workers for material collected in the Alps[4] and in Greenland[5]. The *C. pumilum* material, $2n = 90$, which was collected in Surrey, agrees with the count made by Söllner[6] for Swiss material. In the Surrey material, the higher number $2n = 95$ was more common than $2n = 90$.

## A Method of obtaining Phloem Sap via the Mouth-parts of Aphids

Although aphids and coccids are known as 'sucking' insects, suggestions have been made from time to time[1] that forces within the plant, set up by or even independent of the insect, assisted in the feeding process. Yust and Fulton[2] observed fluid exuding from broken-off mouth-parts left embedded in lemons after detachment of the coccids which had been feeding there. The exudate formed pools on the lemon skins from which samples were taken for sugar analyses. When experiments on the feeding preferences of *Aphis fabae* Scopoli[3] were extended to the comparison of turgid and wilting leaves on otherwise similar plants, the wilting leaves proved to be less acceptable to the aphids. The inference that aphids depend less on their own sucking power than on the turgor pressure in the plant tissue, to maintain the flow of plant sap through the exceedingly fine food canal within their maxillary stylets, was checked by severing the mouth-parts of *A. fabae* individuals feeding on beans. Here, too, fluid was observed to exude from the stylet stumps left projecting from the plant surface.

The technique of obtaining sap from severed aphid stylets has been developed since (by T. E. M.) using the lachnid, *Tuberolachnus salignus* (Gmelin), a conveniently large species colonizing the branches of *Salix* spp. That part of the aphid's rostrum which remains outside the plant during feeding can be severed by a clean cut down on to the bark, without dislodging the stylet tips from their normal situation inside a phloem sieve-tube. The operation can be done on living insects on intact growing plants. The exuding sap can be collected continuously by sleeving the projecting stylet stump in the end of a capillary tube. Exudate has been collected in this way at the rate of about 1 cu. mm. per hour uninterruptedly for periods of up to four days. Very similar rates of honey-dew excretion were recorded from adjacent intact aphids, suggesting that the force responsible for moving the sap out of the plant into the normally feeding insect is provided almost entirely by the pressure in the phloem sieve-tubes themselves. The chemical evidence confirms the view that the stylet exudate is the same as the sap ingested by aphids.

This method of obtaining phloem sap is now in routine use in a study of aphid nutrition, and might also be of use to plant physiologists. It is possible that stylet exudate differs somewhat from sieve-tube sap in an aphid-free plant. But the resemblance should be closer than that of extracts of whole phloem tissue, on which past studies of translocation, for example, have so largely been based.

## Shell Regeneration in some British Molluscs

A study of shell regeneration in *Helix aspersa* (Müller)[1] showed that this snail was able to repair its shell with rapidity, chiefly by virtue of the speed with which amoebocytes could transport materials to the damaged area, either from the digestive gland or from other parts of the shell. It was of considerable interest, therefore, to investigate whether a similar process could operate in other Mollusca, and particularly whether there was any distinction between snails in different habitats.

As a result of investigations on a limited number of species, carried out along the same lines as those used for *Helix aspersa*[1], it was established that the following land snails could regenerate their shell as readily as could *Helix aspersa* :

Helicidae
*Helicella itala* (L.)
*Helicella caperata* (Montagu)
*Cochlicella acuta* (Müller)
*Monacha cantiana* (Montagu)
*Monacha cartusiana* (Müller)
*Hygromia striolata* (Pfeiffer)
*Hygromia subrufescens* (Muller)
*Hygromia hispida* (L.)
*Helix hortensis* (Müller)
*Helix nemoralis* (L.)
*Helix pomatia* (L.)
*Arianta arbustorum* (L.)

Clausiliidae
*Balea perversa* (L.)
*Clausilia rugosa* (Draparnaud)
*Marpessa laminata* (Montagu)

Succineidae
*Succinea elegans* (Risso)
*Succinea putris* (L.)

It was of interest that the largest land snail, *Achatina fulica* (Ferssac.), was also able to regenerate its shell.

These terrestrial gastropods similarly stored calcium products within protein spheres in the digestive gland. Removal of pieces of shell in all these species stimulated amœbocytes to withdraw materials from these stores for the repair of the shell. Other amœbocytes, under such conditions, were demonstrated withdrawing calcium carbonate and proteins from small pieces of original shell placed over the damaged area. Possibly all land Pulmonates are similarly able to repair damage to the shell. Certainly any land snail (unless living continuously in a very humid atmosphere) would need to be able to protect its delicate internal organs efficiently to prevent desiccation.

This regenerative ability is not shared by the Prosobranch *Pomatia elegans* (Müller). Similarly, intertidal Prosobranchs do not cover over damaged shell areas as do the Pulmonates during experimental periods of four weeks. Yet, by contrast, those land Pulmonates that were investigated protected a damaged area of 1 sq. cm. within three hours and continued to thicken the regenerating tissues for at least another forty-eight hours.

Shell repair in land Pulmonates is a process comparable with shell thickening, both involving calcification of successive organic membranes. In those intertidal and marine species examined there was a failure to secrete an initial organic membrane over the damaged area. If this is artificially introduced, in the form, for example, of a glass coverslip[2], then repair is possible, although more slowly than in the land Pulmonates. The marine Mollusca that were examined and were unable to regenerate their shell, in the absence of an artificial covering, within a period of four weeks were :

Prosobranchia
*Haliotis tuberculata* (L.)
*Emarginula reticulata mülleri* (Forbes and Hanley)
*Diodora apertura* (Montagu)
*Patella vulgata* (L.)
*Patella depressa* (Pennant)
*Patina pellucida* (L.)
*Patina laevis* (Pennant)
*Calliostoma zizyphinum conuloide* (Lamarck)
*Gibbula cineraria* (L.)
*Gibbula umbilicalis* (da Costa)
*Gibbula magnus tuberculata* (da Costa)
*Osilinus lineatus* (da Costa)
*Lacuna parva* (da Costa)
*Littorina saxatilis rudis* (Maton)
*Littorina saxatilis saxatilis* (Olivi)
*Littorina rudis* (Maton)
*Littorina littorea* (L.)
*Neritoides littoralis* (L.)
*Turritella communis* (Risso)
*Crepidula fornicata* (L.)
*Natica catena* (da Costa)
*Natica montagui* (Forbes)
*Lamellaria latens* (Muller)
*Trivia monacha* (da Costa)
*Nucella lapillus* (L.)
*Ocenebra erinacea* (L.)
*Buccinum undatum undatum* (L.)
*Hinia reticulatus* (L.)

Opisthobranchia
*Acteon tornatilis* (L.)
*Triola punctostriata* (Mighels and Adams)
*Aplysia punctata* (Cuvier)

Lamellibranchiata
*Anomia ephippium* (L.)
*Mytilus edulis* (L.)
*Chlamys varia* (L.)
*Cardium edule edule* (L.)
*Cardium aculeatum* (L.)
*Venus verrucosa* (L.)

The freshwater species *Viviparus viviparus* (L.) has been shown by Heaysman[3] to repair its shell, though rather irregularly and not with the same speed as *Helix aspersa*.

Bevelander[4] and Heaysman[3] have both established that the marine and freshwater species that they examined could absorb calcium directly from their environment. Neither the freshwater nor the marine species are subjected to the possibility of desiccation and, provided their body fluids are isotonic with the water in which they are living, damage to the shell need not be serious to the animal. Spherules containing calcium were not found in the digestive gland of the marine species that were studied. Again, surrounded with a constant supply, the need for the accumulation of calcium reserves is much less important here than for the land molluscs that are usually entirely dependent on very low concentrations of calcium from their foods. Those that live on calcareous soils have a richer calcium supply and consequently have thicker shells.

The amœbocytes that carry the necessary materials for shell repair and shell thickening play a vital part in the preservation of land snails, since damage to the shell under natural conditions is fairly common, judged by the numbers of snails that are found in the wild with repaired shells. Probably, as Heaysman suggests[3], these same amœbocytes play only a minor part in the formation of new shell, since shell-growth and shell-repair are quite different processes, the former associated with the growth of the whole animal, the latter with 'first aid' to an injury. Land Pulmonates may well owe their ability to live away from water to the speed with which these amœbocytes can work, particularly when it is found that none of the land Pulmonates examined failed to produce large numbers of these amœbocytes when they were required.

## Detection of Phosphate Esters on Paper Chromatograms

PHOSPHATE esters separated on paper chromatograms are usually detected by degrading them on the paper with acid to give *ortho*-phosphoric acid and detecting this by the reaction with molybdate and a reducing reagent. The procedure of Hanes and Isherwood[1] is based upon this and is widely used. This technique suffers from two disadvantages. In the first place, the prolonged initial 'digestion' necessary to break down the more resistant esters frequently leaves the paper in a very fragile state ; and secondly, further analyses cannot be carried out on the spot after treatment. In order to avoid these disadvantages the following technique was developed. It depends upon the fixation of ferric ions by the esters and the reaction of the free ferric ion with salicylsulphonic acid. If the paper is not strongly buffered it is sprayed with 0·1 per cent $FeCl_3.6H_2O$ in 80 per cent alcohol, dried in air at room temperature and then sprayed with 1 per cent salicylsulphonic acid in 80 per cent alcohol. Upon drying, the phosphates appear as white spots on a pale mauve background, *ortho*-phosphate having a band of deeper mauve surrounding it. The colour formation occurs only when the *p*H of the residual moisture in the paper is about 1·5–2·5. This can be checked conveniently with thymol blue, since the colour formation occurs most satisfactorily when the paper just turns this indicator red. Further indications of unsatisfactory *p*H are that below this range no colour is formed, whereas above the range the colour is orange-yellow and definition of the spots is very poor.

When the chromatogram is heavily buffered, modifications to the above reagents are necessary. For example, when there is strong buffering on the alkaline side, it may be necessary to increase the concentration of salicylsulphonic acid to about 10 per cent; when buffering occurs at a low *p*H, the sodium salt may be used.

Other spot indicators of ferric ions have also given good results; but they were either nitrogenous compounds that would interfere with nitrogen determinations or gave colours that faded in light.

Before elution of the chromatogram spots a permanent record of the chromatogram can be made by taking a contact print on a document printing paper such as Ilford No. 50. The colour lends itself well to this, and prints can be obtained that give even better definition of the spots than the original chromatogram.

If a sufficient quantity of ester is present, it can be located on the paper before spraying with salicylsulphonic acid by observing the paper in transmitted daylight or ultra-violet light from a low-pressure mercury lamp incorporating a Wood's filter.

The technique described permits the detection of 1–2 μgm. phosphorus, as phosphate ester, distributed over an area of about 1 sq. cm. The treatment is sufficiently mild not to cause any significant breakdown of adenosine triphosphate providing elution is carried out on the same day as the spraying.

We wish to record our thanks to Major L. H. Kent for his advice and interest. Acknowledgment is made to the Chief Scientist, Ministry of Supply, for permission to publish this communication.

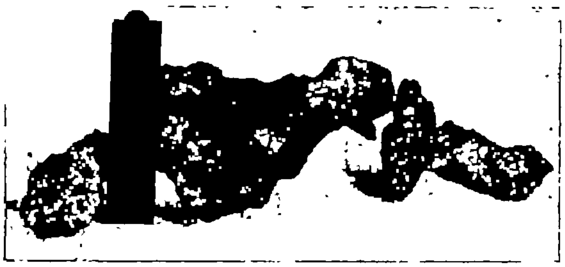
## Vesicular Laterite

The suggestion has been made that the vesicular form of lateritic ironstone owes its characteristic sponge-like structure to termite action, presumably to burrowing by these insects before the material hardened[1].

It is possible that termite action may be responsible in some instances for the perforations; but evidence from the Aripo Savannah in Trinidad (which botanically interesting area receives special mention in Charles Kingsley's "At Last") indicates that vesicles may be a normal morphological feature. The soil profile on this savanna consists of a grey sandy upper layer of about a foot to eighteen inches depth, grading into a material with the consistency of 'Plasticine' with pronounced reddish-yellow mottling. During the wet season, May–December, the water-table lies at or near the surface of the ground, while during the dry season, January–April, it may recede six or more feet. The site is a level one and conditions are correct for the development of a 'ground-water laterite'.

By a fortunate chance during the Second World War, roads were made through this area for military purposes. The area is unfit for agriculture, and had it not been for this chance the present observations might not have been so readily made.

Making of the roads, or more correctly the making of drains at the road-sides, has resulted in the exposure of the mottled horizon. The result, which could scarcely have been predicted by mere inspection of the undisturbed profile, is that 'ironstone' fragments, ranging through all degrees of hardness to completely indurated, have been isolated and stand out on short columns of softer material. They range in size from grain size to more than six inches in length. The larger fragments have the grotesque shapes characteristic of the 'fossil' laterite of Uganda and elsewhere, and which in this case are determined by the irregular shapes of the mottles from which they have been formed. Some of the fragments show smooth-sided perforations, the contents of which have been washed out by rain. The accompanying photograph illustrates one such fragment.



It is suggested that the undisturbed profile represents a stage preceding that which, by progressive enlargement and ultimate contact and fusion of the mottles, would furnish on induration and removal of the softer enclosed material a more or less continuous pavement of vesicular ironstone.

A mound-building termite does occur in the area (*Nasutitermes ephratae*)[2]; but its mounds are infrequent in occurrence and small in size (less than 2 ft. high with a base of about 1½ ft.) There was no sign of termite burrows in the pits examined, and termite action may be excluded in this case as in any way contributing to the whorls and perforations of the indurated material.

The profile will now be studied critically, with the view of tracing the stages of induration, etc., and the findings will be published in due course.

# FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

## Monday, March 23

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY (in the Main Chemical Lecture Theatre, Royal College of Science, Imperial Institute Road, London, S.W.7), at 4 p.m.—Prof. V. Prelog (Zürich): "Organic Chemistry". (Further Lectures on March 24 and 27.)

ROYAL GEOGRAPHICAL SOCIETY (at 1 Kensington Gore, London, S.W.7), at 5 p.m.—Dr. G. P. Wibberley: "Some Aspects of Problem Rural Areas in Great Britain".

INSTITUTE OF METALS (at the Royal Institution, 21 Albemarle Street, London, W.1), at 6 p.m.—Sir Christopher Hinton: "The Present and Future Requirements of the Chemical Engineer" (Annual May Lecture).

## Tuesday, March 24

CHADWICK PUBLIC LECTURE (in the Lecture Hall, Chadwick Department of Civil and Municipal Engineering, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Mr. H. R. Oakley: "Public Health Engineering—Research and Training".*

INSTITUTE OF PETROLEUM (at Manson House, 26 Portland Place, London, W.1), at 5.30 p.m.—Dr. J. B. Matthews, Mr. J. H. T. Brook, Mr. H. C. Evans, Mr. J. Hughes and Dr. R. P. Taylor: Papers on "The Examination of Used Lubricating Oils".

ROYAL SOCIETY OF MEDICINE, MEDICINE SECTION (at 1 Wimpole Street, London, W.1), at 8 p.m.—Discussion on "The Chemotherapy of the Reticuloses".

## Tuesday, March 24—Thursday, March 26

INSTITUTE OF METALS (at the Park Lane Hotel, Piccadilly, London, W.1).—Annual General Meeting.

**Tuesday, March 24**

Presidential Address.

**Wednesday, March 25**

Symposium on "Control of Quality in the Production of Wrought Non-Ferrous Metals".

## Wednesday, March 25

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W.C.2), at 2.30 p.m.—Mr. Peter Opie: "The Collection of Folklore in England".

PHYSICAL SOCIETY, COLOUR GROUP (in the Physics Department, Imperial College of Science and Technology, Imperial Institute Road, London, S.W.7), at 2.15 p.m.—Annual General Meeting; at 3.30 p.m.—Dr. T. Vickerstaff: "Colour Problems in the Dyeing Industry" (Chairman's Address).

ROYAL STATISTICAL SOCIETY (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 5.15 p.m.—Miss M. S. Rix: "Construction of an Index Number of Gilt-Edged Values".

EUGENICS SOCIETY (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Dr. Gertrude Willoughby: "Population Problems and Family Policy in France".*

SOCIETY OF CHEMICAL INDUSTRY, NUTRITION PANEL of the FOOD GROUP (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 6.15 p.m.—Mr. N. W. Pirie, F.R.S., and Dr. A. C. Thaysen: "Newer Sources of Foodstuffs" (Food and the Future, 3).

## Wednesday, March 25—Friday, March 27

INSTITUTION OF NAVAL ARCHITECTS (on board the *Wellington*, Headquarters Ship of the Honourable Company of Master Mariners, Temple Stairs, Victoria Embankment, London, W.C.2), at 10.15 a.m. each day.—Spring Meeting.

INSTITUTE OF PHYSICS (at Bedford College, Regent's Park, London, N.W.1).—Conference on "Static Electrification".

## Thursday, March 26

MINERALOGICAL SOCIETY (at the Geological Society of London, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Scientific Papers.

ROYAL ANTHROPOLOGICAL INSTITUTE (at 21 Bedford Square, London, W.C.1), at 5.30 p.m.—Dr. S. Biobaku: "Egba Traditional Authorities".

## Thursday, March 26—Friday, March 27

FARADAY SOCIETY, COLLOID AND BIOPHYSICS COMMITTEE (in the Wheatstone Physics Laboratory, King's College, Strand, London, W.C.2).—Discussion on "The Nature and Structure of Collagen".

## Friday, March 27

SOCIETY OF CHEMICAL INDUSTRY, CORROSION GROUP (joint meeting with the MANCHESTER SECTION of the S.C.I., and the ROYAL INSTITUTE OF CHEMISTRY, in the Chemistry Lecture Theatre, The University, Manchester), at 10.30 a.m.—Symposium on "Corrosion Inhibitors".

BIOCHEMICAL SOCIETY (in the Department of Biochemistry, University College, Gower Street, London, W.C.1), at 11 a.m.—Annual General Meeting; Scientific Papers.

ROYAL SCOTTISH FORESTRY SOCIETY (in the Large Lecture Hall, Royal Botanic Garden, Inverleith Row, Edinburgh), at 2 p.m.—100th Annual Business Meeting.

ROYAL ASTRONOMICAL SOCIETY (at Burlington House, Piccadilly, London, W.1), at 4.15 p.m.—Geophysical Discussion on "Magmatic Diffusion and the Hot Hydrosphere".

INSTITUTION OF MECHANICAL ENGINEERS (at Storey's Gate, St. James's Park, London, S.W.1), at 5.30 p.m.—Annual General Meeting.

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 9 p.m.—Sir Eric Rideal, F.R.S.: "Count Rumford and the Royal Institution".

ROYAL AERONAUTICAL SOCIETY (in the Chemistry Lecture Theatre, University College, Gower Street, London, W.C.1).—Discussion on "Fatigue".

## Friday, March 27—Saturday, March 28

BRITISH PHARMACOLOGICAL SOCIETY (joint meeting with the FINE CHEMICALS GROUP of the SOCIETY OF CHEMICAL INDUSTRY, at the Wellcome Research Institution, 183 Euston Road, London, N.W.1), at 9.30 a.m. and 2.30 p.m. each day.—Symposium on "Anticholinesterases".

---

# APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

ASSISTANT EXPERIMENTAL OFFICER (preferably with experience in biological and/or physical chemistry) IN THE BACTERIOLOGY DEPARTMENT—The Secretary, National Institute for Research in Dairying, Shinfield, Reading (March 28).

LECTURER IN HUMAN PHYSIOLOGY, and a LECTURER IN EXPERIMENTAL (Mammalian) PHYSIOLOGY—The Secretary, St. Mary's Hospital Medical School, Paddington, London, W.2 (March 28).

SCIENTIFIC OFFICERS AT THE NATIONAL AERONAUTICAL ESTABLISHMENT, Bedford, to plan and conduct tests in supersonic wind tunnels and to interpret results—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting C.117/53A (March 28).

ASSISTANT ADVISER (with a degree or the national diploma in horticulture) IN HORTICULTURE—The Secretary, North of Scotland College of Agriculture, 41½ Union Street, Aberdeen (March 31).

ASSISTANT LECTURER (probationary) IN METALLURGY—The Registrar, University College, Singleton Park, Swansea (March 31).

SENIOR RESEARCH STUDENTSHIP IN METALLURGY, and a probationary ASSISTANT LECTURESHIP IN METALLURGY—The Registrar, University College, Singleton Park, Swansea (March 31).

EXPERIMENTAL OFFICER (Grade III) AT THE AERONAUTICAL RESEARCH LABORATORIES, Fishermen's Bend, Melbourne, to carry out wind tunnel investigations related to the development of new aircraft types—The Senior Representative, Department of Supply, Canberra House, 87 Jermyn Street, London, S.W.1, quoting No. 248 (April 2).

RESEARCH ASSISTANT (Grade II) IN THE DEPARTMENT OF TEXTILES, Victoria and Albert Museum—The Secretary, Civil Service Commission, Burlington Gardens, London, W.1, quoting 237/53 (April 2).

LECTURER (Grade II) IN MINING (Coal), and a RESEARCH FELLOW IN COAL TREATMENT—The Registrar, The University, Edgbaston, Birmingham 15 (April 4).

RESEARCH OFFICER TO THE PHYSICAL CHEMISTRY SECTION, Division of Industrial Chemistry, Fishermen's Bend, Melbourne, to investigate the properties of solutions of polyelectrolytes—The Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2, quoting No. 4173 (April 4).

LECTURER and an ASSISTANT LECTURER IN (*a*) GAS ENGINEERING AND (*b*) FUEL TECHNOLOGY—The Registrar, The University, Leeds 2 (April 6).

LECTURER (Grade III or II, preferably with interests in pure mathematics) IN MATHEMATICS—The Registrar, The University, Bristol 8 (April 7).

ASSISTANT LECTURER (graduate with qualifications and/or experience in heavy electrical engineering) IN ELECTRICAL ENGINEERING—The Registrar, The University, Manchester 13 (April 10).

ASSISTANT LECTURER IN MATHEMATICS (preferably with special qualifications in algebra or geometry)—The Registrar, Queen Mary College, Mile End Road, London, E.1 (April 10).

CHIEF CHEMIST (with honours degree in chemistry, and with experience in inorganic analysis) IN THE GEOLOGICAL SURVEY, Southern Rhodesia—The Secretary, Rhodesia House, 429 Strand, London, W.C.2 (April 10).

SENIOR LECTURER-IN-CHARGE IN THE DEPARTMENT OF MINING, University of Sydney—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (April 10).

LECTURER OR ASSISTANT LECTURER IN MATHEMATICS at University College, Ibadan, Nigeria—The Secretary, Inter-University Council for Higher Education in the Colonies, 1 Gordon Square, London, W.C.1 (April 11).

RESEARCH CHEMIST to take charge of the Regional Chemical Laboratory of the Division of Soils of the Commonwealth Scientific and Industrial Research Organization, at Canberra—The Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2, quoting No. 270/83 (April 11).

RESEARCH OFFICER TO THE MINERALS UTILIZATION SECTION, Division of Industrial Chemistry, Fishermen's Bend, Melbourne, to undertake research work in the field of inorganic and physical chemistry—The Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2, quoting No. 4187 (April 11).

SCIENTIFIC OFFICER (with honours degree in botany) for potato breeding with special reference to breeding for resistance to potato root eelworm—The Secretary, Scottish Plant Breeding Station, Craigs House, Corstorphine, Edinburgh 12 (April 11).

SCIENTIST (Grade III) (with a good honours degree in geology or chemistry, and some experience or special interest in preparing scientific papers and reports) on the Coal Survey headquarters in London, mainly to assist in the preparation and editing of Coal Survey publications—The National Coal Board, Establishments (Personnel), Hobart House, Grosvenor Place, London, S.W.1, quoting TT/606 (April 11).

SENIOR RESEARCH OFFICER (Theoretical Physicist) IN THE DIVISION OF ELECTROTECHNOLOGY, National Standards Laboratory, Sydney—The Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2, quoting No. 4078 (April 11).

EXCHANGE FELLOWSHIPS IN CANCER RESEARCH offered by the National Cancer Institute of Canada and the American Cancer Society—The Secretary-General, British Empire Cancer Campaign, 11 Grosvenor Crescent, London, S.W.1, endorsed 'Exchange Fellowship' (April 12).

ENGINEERS or CHEMICAL ENGINEERS (Senior Lecturers or Lecturers) with wide practical experience of food processing operations, for example, canning, dehydration—The Registrar, National College of Food Technology, Cranwood Street, London, E.C.1 (April 15).

LECTURER IN PHYSIOLOGY at the University of Otago, Dunedin, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (April 15).

RESEARCH FELLOWSHIPS IN GOVERNMENT SCIENTIFIC ESTABLISHMENTS for research into subjects of importance to H.M. Government—The Civil Service Commission, Scientific Branch, Trinidad House, Old Burlington Street, London, W.1, quoting S.4192/53 (April 15).

ASSISTANT LECTURER (with honours degree in chemistry, and research experience) IN THE DEPARTMENT OF CHEMISTRY—The Secretary, Bedford College, Regent's Park, London, N.W.1 (April 17).

RAMSAY MEMORIAL FELLOWSHIPS FOR ADVANCED STUDENTS OF CHEMISTRY—The Joint Honorary Secretaries, Ramsay Memorial Fellowships Trust, University College, Gower Street, London, W.C.1 (April 17).

I.C.I. RESEARCH FELLOWSHIPS IN CHEMISTRY, PHYSICS and allied subjects, including the biological application of chemistry—The Registrar, University Office, 46 North Bailey, Durham (April 18).

LECTURER IN CHEMICAL ENGINEERING—The Registrar, King's College, Newcastle-upon-Tyne (April 18).

SCIENTIST (Grade II), a SCIENTIST (Grade III) or SCIENTIFIC TECHNICAL OFFICER (Grade I) on the staff of the Director of Scientific Control, to carry out environmental studies at collieries in connexion with a long-term Field Research into the occurrence and causes of pneumoconiosis—The National Coal Board, Establishments (Personnel), Hobart House, Grosvenor Place, London, S.W.1, quoting TT/607 (April 18).

UNDERGRADUATE SCHOLARSHIPS, POST-GRADUATE SCHOLARSHIPS, and RESEARCH FELLOWSHIPS FOR UNIVERSITY STUDY IN MECHANICAL ENGINEERING, TEXTILE ENGINEERING, TEXTILE TECHNOLOGY and certain allied subjects—The Secretary, Sir Walter Preston Scholarship Trust, Textile Machinery Makers, Ltd., 60 Huddersfield Road, Oldham (April 18).

ASSISTANT LECTURERS IN BOTANY, with special interests in either plant ecology and/or plant morphology, or mycology and/or microbiology—The Principal, Royal Holloway College, Englefield Green, Surrey (April 20).

ASSISTANT LECTURERS IN PHILOSOPHY, PHYSICS and GEOLOGY, and a LECTURER or ASSISTANT LECTURER IN GEOGRAPHY—The Registrar, University College of North Staffordshire, Keele, Staffs (April 22).

CHAIR OF PHYSICS in the University of Hong Kong—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (April 30).

DIRECTOR—The Secretary, John Innes Horticultural Institution, Bayfordbury, Hertford (April 30).

INTERMEDIATE and JUNIOR FELLOWSHIPS IN CANCER RESEARCH—The Secretary-General, British Empire Cancer Campaign, 11 Grosvenor Crescent, London, S.W.1, endorsed 'Intermediate' or 'Junior' Fellowship (April 30).

JUNIOR PLANT PHYSIOLOGIST (with good honours degree in botany with special reference to plant physiology, and preferably with some postgraduate experience) under the Colonial Development and Welfare Cocoa Research Scheme—The Secretary, Imperial College of Tropical Agriculture, 40 Norfolk Street, London, W.C.2 (April 30).

LECTURER IN GEOLOGY at the University of Hong Kong—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (April 30).

LECTURER IN THEORETICAL PHYSICS—The Secretary of University Court, The University, Glasgow (April 30).

GRADUATE ELECTRONIC ENGINEER FOR WORK IN THE DEPARTMENT OF ANATOMY on the problem of counting and measuring microscopic particles, for research in television microscopy and its application to central nervous system—The Secretary, University College, Gower Street, London, W.C.1 (May 1).

I.C.I. RESEARCH FELLOWSHIPS IN PHYSICS, CHEMISTRY or related subjects—The Registrar, University Registry, Oxford (May 1).

LECTURER or ASSISTANT LECTURER IN CHEMISTRY at University College of the West Indies—The Secretary, Inter-University Council for Higher Education in the Colonies, 1 Gordon Square, London, W.C.1 (May 1).

RESEARCH SCHOLARSHIPS, GRADUATE SCHOLARSHIPS and STUDENT SCHOLARSHIPS—The Secretary, Institution of Electrical Engineers, Savoy Place, London, W.C.2 (May 1 for Student Scholarships, June 1 for Graduate and Research Scholarships).

HUNTLEY AND PALMER'S AGRICULTURAL RESEARCH FELLOWSHIP—The Registrar, The University, Reading (May 2).

SENIOR LECTURER IN HYDRAULIC ENGINEERING at the University of Melbourne—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (May 18).

BOOTS RESEARCH SCHOLARSHIP at the Long Ashton Agricultural and Horticultural Research Station—The Registrar, The University, Bristol (May 31).

JUNIOR LECTURER IN THE DEPARTMENT OF ENTOMOLOGY—The Assistant Dean, London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1 (May 31).

LECTURER IN THE DEPARTMENT OF LAND SURVEYING, University of Natal, Durban—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (May 31).

BURSARIES IN CONCRETE TECHNOLOGY tenable at the Imperial College of Science and Technology—The Deputy Registrar, City and Guilds College, Exhibition Road, London, S.W.7 (June 1).

ENGLISH ELECTRIC COMPANY'S BURSARIES IN HYDRO-POWER ENGINEERING, tenable in the Civil Engineering Department of the Imperial College of Science and Technology—The Deputy Registrar, City and Guilds College, Exhibition Road, London, S.W.7 (June 1).

NUFFIELD RESEARCH FELLOWSHIP for research on the scientific aspects of ageing—The Secretary, Nuffield Foundation, Nuffield Lodge, Regent's Park, London, N.W.1 (June 1).

UNIVERSITY LECTURER IN ANTHROPOLOGY, and an ASSISTANT CURATOR IN THE MUSEUM OF ARCHÆOLOGY AND ETHNOLOGY—The Secretary of the Appointments Committee, Faculty of Archæology and Anthropology, Museum of Archæology and Ethnology, Downing Street, Cambridge (June 1).

AGRICULTURAL ENGINEER, British Honduras, to organize and control two land clearing units for agricultural developments—The Director of Recruitment, Colonial Office, Great Smith Street, London, S.W.1, quoting CDE.63/31/01.

ENGINEER in the Ministry of Supply at Fort Halstead, to supervise design of test models and equipment, and operation and maintenance of large wind and water tunnels and other installations—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting C.139/53A

MECHANICAL ENGINEER or PHYSICIST (with strong interest in technique of mechanical test creep of materials and instrumentation generally) FOR METALLURGY DEPARTMENT of the Royal Aircraft Establishment, Farnborough—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting C.141/53A.

PRODUCTION CHEMISTS at Royal Ordnance Factories in S.W. Scotland, Lancs, Somerset and South Wales, to assist in technical control or administration for explosives and acids manufacture or ammunition filling, including development work—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting F.77/53A.

RESEARCH ASSISTANT (B.Sc. standard) IN THE CLINICAL RESEARCH LABORATORY, to work in the steroid field—The Secretary, Sheffield No. 1 Hospital Management Committee, Nether Edge Hospital, Sheffield 11.

SENIOR BIOCHEMIST (non-medical) IN THE AREA PATHOLOGICAL LABORATORY—The Secretary, Shotley Bridge General Hospital, Shotley Bridge, Consett, Co. Durham.

SENIOR EXECUTIVE ENGINEER, Public Works Department, Aden—The Director of Recruitment, Colonial Office, Great Smith Street, London, S.W.1, quoting CDE.112/2/01.

SENIOR LECTURER IN PHYSICS, and a LECTURER IN TECHNICAL CHEMISTRY—The Secretary, Royal Technical College, Glasgow, C.1.

STATISTICIAN to help in planning and carrying out technological investigations in mills—The Secretary, British Rayon Research Association, Barton Dock Road, Urmston, Manchester.

TOBACCO OFFICER, Department of Agriculture, Tanganyika, to take charge of the Tobacco Experiment Farm—The Director of Recruitment, Colonial Office, Great Smith Street, London, S.W.1, quoting CDE.63/8/02.

# FUNCTION OF TECHNOLOGICAL EDUCATION

THE collection of essays constituting the preliminary survey of the nature and efficacy of technical education, which the United Nations Educational, Scientific and Cultural Organization has published under the title "Education in a Technological Society"*, emphasizes the need for social foresight in estimating technological needs and in providing suitable education. Much more is intended by this than forecasting future requirements for particular classes of technological or technical experts and attempting to adjust supply to demand. It envisages also the question of flexibility so as to ease transfer from one occupation to another, and the problems which are presented by changing age-structure and elderly workers.

This need for social insight has been well indicated by a number of recent management studies in Great Britain; and it is further stressed in an international study of the "Sense of Belonging in Industry" made by two of the authors of one of these studies, whose services were made available by the British Institute of Management. This study also has been published by the United Nations Educational, Scientific and Cultural Organization under the title "The Community Factor in Modern Technology"†. Following a well-documented review of the discords of industrial society, it presents, first, twelve European studies of organizations which helped to maintain a community and of organizations which fostered the creation of a sense of community where none had existed, and, secondly, two case studies of the process of maintaining and fostering communities. The latter utilize material already reported in Great Britain; but the conclusions drawn regarding satisfactions in industry and on the need and methods for study outlined in the following two chapters are not based simply on this evidence.

The main purpose of the book is to demonstrate the reason for believing that industry can play a major part in maintaining existing, and in fostering the growth of new, communities. This belief has been confirmed whenever the discords of industrial society have been strident enough to demand analysis, and Mr. Scott and Mr. Lynton consider it would be reasonable to expect that attention to the community factor in industry would result in many individuals finding the security and stability which they now lack. This change should greatly reduce neurotic and anti-social behaviour: much psychosomatic illness is traceable to industrial situations. Responsibility can also reasonably be expected to be diffused through an organization, community, region or nation, leading to more equal sharing of burdens and satisfactions. This might revise the growing tendency of society to consist of a few at the centre with too much to do, and many at the periphery with no community responsibilities.

---

* Education in a Technological Society: a Preliminary International Survey of the Nature and Efficacy of Technical Education. (Tensions and Technology Series.) Pp. 76. 200 francs; 4s.; 75 cents.

† The Community Factor in Modern Technology: an International Study of the 'Sense of Belonging' in Industry. By Jerome F Scott and R. P. Lynton. (Tensions and Technology Series.) Pp. 170. 300 francs; 6s.; 1 dollar.

(Paris: Unesco; London: H.M Stationery Office, 1952.)

In drawing this conclusion, the report is stating in other words and in a fresh context the importance of genuine local self-government as the basis of a democratic society, and the whole trend of the conclusions of Mr. Scott and Mr. Lynton points to the vital necessity for reform at that level as much as for developments in industry. They suggest that a balance and integration of social classes and economic interests may be expected to replace the cycle of domination of society by successive groups, and that the reconciliation of interests would thus be possible without unmanageable conflicts. It requires an integrated community to enable the various interests to co-operate around the fundamental principle that wealth is increased only through increased productivity, not through strife; and the report suggests that our capacity to communicate with others may be expected to develop greatly, rendering it easier to become adapted to changes of all sorts, since we should have roots in communities, and daily practice of effective communication and adaptation.

In this sense, responsible membership of a real community is training for living in the world community; and as status systems attuned to the needs of the times develop, we may expect really representative institutions to throw up regional and national leaders. Community could thus co-operate with community, region with region, and national policies could be evolved and continuously adapted. Moreover, the growth of many spontaneous and autonomous arrangements between effective social institutions and between communities may be expected to replace some national policies which have been born of the failures of institutions and communities and now hinder their growth.

Mr. Scott and Mr. Lynton in this report provide a reasonable basis for such expectations; although, in their summing up, they give insufficient weight to the obstacles and prejudices which such trends will have to overcome even within any one country. We may perhaps disregard for the present any effect they are likely to have on international co-operation; but in technological development and in both the planning and the content of technological and technical education, due weight must be given to the implications of such factors. They are highly relevant to discussions on modern industrial organization such as Political and Economic Planning has published in two recent broadsheets: No. 348, "New Thinking on Monopoly", and No. 350, "The Structure of Industry and the Technical Revolution".

The first of these broadsheets traces the development of thought on monopoly up to the present time, when it is seen as a problem of power, and, as such, a question for politicians rather than economists. The efficacy or otherwise of the means available for counteracting monopoly obviously can have powerful repercussions on the development of community ideas; but the second broadsheet is concerned essentially with the various technological and other factors affecting the growth of business firms. Efficiency, it is emphasized in the Unesco report, is no longer seen almost as a function of size; on the contrary, even in industries most favourably disposed to mass production, there is a tendency, defended essentially in social terms, to limit the size of each production unit. Managers tend to be regarded as trustees of an institution; and explicit evaluation of human affairs is replacing implicit evaluation.

The PEP broadsheet is emphatic that, while industrial concentration has continued in the past few years, the dominant forces are now technological rather than financial or economic. Over many years such factors as the development of organized research and the advent of synthetic materials, with, as corollary, the huge initial investment demanded by new processes, have broken down traditional barriers between industries and stimulated the development both of the firm making a variety of products and of joint enterprises of several companies, not necessarily from the same industry. Both the inventive and financial resources of the nation are being canalized more and more through the large concern, whether publicly or privately owned.

The prime influence in this expansion across industrial boundaries has been the growing complexity of modern industry, under the influence, first of the chemical revolution in the second half of the nineteenth century, and later the development of synthetic products in the second and third decades of the twentieth. While the technical implications for different industries of such developments as plastics—'Terylene' and nylon, for example—have been adequately discussed, their impact on the industrial structure seems to have been neglected, and in directing attention to this as well as to the implications of such changes for the trade unions and for the human side of industry, the broadsheet does a real service. Moreover, it puts in its true perspective the seriousness of inappropriate taxation policies which discourage enterprise at a time when only the really large firm is in a position to carry the heavy overheads represented by research facilities and development from the laboratory, through the pilot plant, to full-scale production.

The broadsheet quotes sufficient examples of joint enterprise to indicate that the analysis of competition simply in terms of competing against other firms in the same industry is no longer tenable. The corollary that each firm is competing to a greater or less extent against every other firm in the economy holds social as well as economic implications far reaching enough to warrant a comprehensive survey of industrial structure such as the broadsheet suggests. The suggestion is further supported by the trend of Mr. Duncan Sandys's recent statement in the House of Commons on progress in the development of the use of atomic energy for industrial purposes. Nothing in that statement encouraged the view that power obtained in this way is likely to be available on a significant scale for industrial purposes at an early date. Mr. Sandys was more concerned to emphasize the technical difficulties still to be overcome, and the need for much more experience before a considered judgment could be formed on the economic soundness of such proposals. None the less, social as well as workers in the Society. In this volume excellent photographs are reproduced of all the presidents past and present of the Society; some of these are, or were, personally known to their British colleagues both for their activities as chemists and for their participation in the Society's activities; but it is highly likely that the name of Charles L. Parsons is known to more chemists in the world than any other associated with the Society's activities. It is probable that the membership of the American Chemical Society by now exceeds the total membership of all other chemical societies outside the Iron Curtain, and one can look forward with hope and enthusiasm to the first centenary of the Society.

ERIC K. RIDEAL

# THE STERLING AREA IN AMERICAN EYES

The Sterling Area

An American Analysis. Prepared under the direction of John M. Cassels. (Published by the Mutual Security Agency Mission to the United Kingdom.) Pp. 672. (London: H.M. Stationery Office, 1951.) 21s. net.

WHEN the Economic Co-operation Administration mission to the United Kingdom began to function in 1948 it immediately felt the inconvenience of its lack of knowledge, not only of the United Kingdom economy but still more of the economies of other British Commonwealth countries and of that strange and amorphous organization summed up as 'the Sterling Area' with which they are financially linked. The information the mission sought was not easily available anywhere, and it was an excellent idea to get together a fact-finding committee to write an objective report on the various members of the Area, from the point of view both of those who had to administer Marshall Aid and of the American public, who might be expected to contribute more willingly if they understood better to what they were contributing. The result is a handsome volume, sumptuously printed in Amsterdam, with innumerable illustrated statistics, some of which are in colour, and a wealth of tables. It contains 671 double-column pages and weighs 5¼ lb.

The American passion for large publications is very difficult for the British to understand, and this one (as it would no doubt be described in the United States) a 'jumbo' even by American standards. It is divided into three parts, described as books. The first summarizes the main features of Sterling Area countries; one chapter describes briefly the United States and Canadian economies by way of contrast and by showing their relations to the Sterling Area. A brief summary of the extent and progress of post-war recovery is then given, and the book ends with what is effectively a review of the Sterling Area considered as a proposition for American investors.

Book 2 consists of a series of lectures on economic geography at a fairly elementary level, going carefully around the components of the Area and summarizing their economic structure: population (size, growth and racial structure), imports and exports (pre- and post-war, by commodity and by country of origin or destination), external capital position and domestic economic policies. Book 3 consists of thirteen chapters, each of which is devoted to describing the world position in respect of some commodity or group of commodities (primary products) important in world trade. This is done with a considerable degree of detail. For example, the chapter on non-ferrous metals gives first a table for twenty non-ferrous metals of United States consumption as a percentage of world, and of United States production. This is followed by an immense table of the production (by weight of metal content) of each of twenty-five non-ferrous metals in each of sixty countries of the world. This in turn is followed by individual studies of tin, copper, aluminium (including bauxite), lead and diamonds.

It will be evident that Books 2 and 3 contain a great deal of information, some of which is not easily available elsewhere and more of which is conveniently brought together for the first time. Most of the information has, inevitably perhaps, been snipped out of books and legal documents (such as the constitutions of the various countries). This matters less in Book 3 than in Book 2, where this type of second-hand knowledge, although not actually incorrect, can give a distorted impression, in that practice often develops a very different emphasis from that apparent in the legal framework. A short visit by a member of the committee to a few leading Sterling Area countries (such as India) would have served to correct this. Again, an over-concentration on trade statistics not infrequently gives a misleading impression, for example, in the case of Ireland, where invisibles in both directions play such an important part in the balance of payments.

The sub-title of the work is "An American Analysis"; this does it both less and more than justice. There is virtually no analysis in the economic sense. On the few occasions when an economic argument is put forward, it tends to be incomprehensible (as when it is stated that devaluation was favoured because it would make British industry more efficient under increased competition from American exporters). The statistics are all of a very 'bread and butter' type and should not be relied on in too great detail.

On the other hand, the study tries very hard (and on the whole succeeds very well) to attain a strictly fair and objective attitude, and to keep American prejudices against the Sterling Area well in the background; indeed, the book should do much to dispel them. Nevertheless, from the British angle the view is, of course, American. For example, the discussion of the change in the position of South Africa, and hence indirectly of the whole Sterling Area, due to the failure of the price of gold to get adjusted to post-war levels, is delicately skated over. Again, while the Sterling Area restrictions on dollar imports are set out at length, there is much less of dollar restrictions on Sterling Area exports, such as tin.

Nevertheless, the British reader will find in the book much that is new to him and on which he would do well to ponder. Especially important is the demonstration of the increased direct dollar earnings of Sterling Area commodities—by-passing the traditional triangle through the United Kingdom (Australian wool is an important example). Such changes as these are very largely the source of the increasing strains which are all too evident in the rigid organization of the Sterling Area. It is vital that we should have them impressed on us in order that they may be relieved before it is too late.

URSULA K. HICKS

# RUMFORD: A BICENTENARY

By THOMAS MARTIN

BENJAMIN THOMPSON, afterwards Count Rumford, was born two hundred years ago (March 26, 1753) at Woburn in Massachusetts, about fifteen miles from Boston. Distinguished as a soldier, a statesman, a philanthropist and a man of science, it is probably in the last of these characters that he is best remembered to-day. He made experiments and reached conclusions of fundamental importance concerning the nature of heat; he was the author of a series of "Essays" on various subjects in pure and applied science which were well known and widely circulated in their day; he was a pioneer in that field of activity which he himself described as the "application of science to the common purposes of life"; and in the pursuit of this object he founded the Royal Institution in London.

Rumford came of the Puritan stock of the original New England settlers, and widely though he departed, in the course of an active and at times adventurous life, from the ways of his forefathers, there is no doubt that their traditions left their mark on his character. Added to his intellectual gifts were a methodical industriousness and a frugal outlook which caused him to take an intense interest in the practical details of his schemes of welfare, while in his personal relations there was often a harsh disregard for the feelings of individuals which was in marked contrast with the professed object of his plans; and it is probably in these characteristics that we may trace his New England origin.

His early life was lived in those troubled years in the American Colonies which led up to the War of Independence. While working as apprentice to a storekeeper, he showed an interest in science and experiment, and attended lectures at Harvard. Later, as a young schoolmaster at Rumford (later Concord) in New Hampshire, he married the widow, fourteen years his senior, of a considerable citizen of that place. It was here that his daughter Sarah, afterwards Countess Rumford, was born.

His military aspirations were gratified when he was commissioned as major in a local regiment of militia; but he was suspected by the townspeople of sympathies for the royalist cause which were too ardent for their liking, and when the troubles came to a head he was obliged to escape from the town. Later, to avoid persecution, he joined the British in Boston, leaving his wife, whom he was never to see again. Henceforth he was an avowed loyalist.

On the evacuation of Boston, Major Thompson was sent with dispatches to London, and before long, such was his initiative and address, was established in the Colonial Office as an under-secretary to the Minister, Lord George Germain. His promotion was rapid. The United States had declared their independence on July 4, 1776; but the war dragged on, and for a time Thompson returned to America, to serve with some distinction in command of a regiment of cavalry with the British forces. Peace was not finally concluded until 1783, when he found himself again in London, a colonel with half-pay on the British establishment.

Seeking fresh fields to conquer, Thompson visited the Continent, and after a brief return to Britain, during which he was knighted by King George III, there followed that most active and fruitful period of his career when for fourteen years he served the Elector of Bavaria. It was in Munich, where he held high military rank and was Privy Councillor of State to the Elector, that his constructive energy and administrative skill found their full outlet. The country was backward and the administration inefficient and corrupt, and Sir Benjamin Thompson's New England soul must have revolted at the incompetence and neglect he saw around him.

He introduced reforms in the army and in many of the Departments of State; but in none of his measures was he more successful than in those for dealing with the problem of mendicancy. After a period of war and political disturbance, the country was infested with beggars whose menaces and extortions seriously alarmed the law-abiding citizens of Munich. Thompson appointed a day when, with the aid of the military, all the vagrants in the capital were arrested. Houses of Industry having been prepared for their reception, and a charitable organization set up to provide the necessary funds, the genuine poor and infirm were relieved and the able-bodied set to useful work. By his enlightened and humane treatment of the destitute and the originality and success of his methods in the Houses of Industry, he established a new system of philanthropy, and his ideas were afterwards applied, often on his personal advice, in many other countries.

This work in Munich aroused his interest in such matters as economy of fuel, the design of stoves and fireplaces and the economical provision of food for large numbers of people; and many of his "Essays", published later, were devoted to these subjects. Rumford stoves were widely used and Rumford soup kitchens set up in London, Paris, Geneva and elsewhere; the soup tickets could be purchased by the charitable and given to the hungry.

The Elector Karl Theodor rewarded Sir Benjamin Thompson by creating him a Count of the Holy Roman Empire, and the new Count took for his title the name, Rumford, of the place in New Hampshire where, after his marriage, he had first been established as a man of substance.

He returned to England in 1798, expecting to be the Bavarian Minister in London, and was grievously disappointed when he found that the British Government would not accept a subject of the King as the representative of a foreign power. He stayed on in London, however, where his fame had travelled before him: William Wilberforce declared in Parliament that it was "a public blessing in such times as these to have such men as Count Rumford" in the country. The Count became a leading member of a group of practical philanthropists, associated in the Society for Bettering the Condition and Increasing the Comforts of the Poor, who were responsible at this time for a number of new enterprises. One of these, the principal object of which was to be the application of science and invention to the improvement of the lot of the working classes, was the Royal Institution; and to this establishment, founded in 1799, Rumford devoted most of his time for upwards of two years.

Rumford's fame during his life-time rested on his public works, and the special feature of his activities, which distinguished him from other professed reformers, was his determination to apply scientific knowledge to the objects of philanthropy. Much of his scientific work had a strictly utilitarian object in view. Throughout the period of his service in Bavaria, however, and indeed all through his life, he returned, in the intervals of his public labours, to the "more pleasing occupations of science and philosophical experiment". These private researches formed the subject of his periodical communications to the Royal Society and other learned bodies, and it is upon them that his enduring reputation as a man of science really depends.

As early as 1778 he carried out in England a series of experiments with gunpowder and firearms. The paper describing this work shows that he was well acquainted with the work of Benjamin Robins, the inventor of the ballistic pendulum, and he used a Robins pendulum to determine the velocities of projectiles. A chance observation of the greater heating of a gun-barrel with a blank charge than when a projectile was fired led him to investigate the source of the heat, and although his explanation of the observation is not very convincing, it shows that he had already begun to think in terms of the generation of heat by mechanical action and to speculate as to the nature of heat itself.

He had made the acquaintance of Sir Joseph Banks and other men of science soon after his arrival in England; and in 1779 was elected a Fellow of the Royal Society.

On a visit to Mannheim in 1785, he made some experiments on heat at the Academy of Sciences. A thermometer was fixed at the centre of a glass tube having a bulb at the end, the bulb immersed in ice or boiling water, and the times noted for the thermometer to fall or rise through certain intervals of temperature. With this apparatus he obtained measures of the conducting power of the contents of the bulb—water, mercury, air at different pressures —or a vacuum. His discovery of the heat-insulating power of a vacuum, or more accurately the reduced conductivity of the imperfect vacuum he obtained, is of particular interest, for it contains the suggestion of the principle used many years later by Sir James Dewar in his vacuum vessels. Another important observation was that moist air conducts more readily than dry.

The experiments begun in Mannheim were continued in Munich, and a more elaborate apparatus devised, which has been erroneously described as Rumford's calorimeter, but which he called his "cylindrical passage thermometer". It was an instrument for measuring conductivity, and with it he made a great many determinations. One of these instruments is preserved at the Royal Institution. The discovery of the superior conductivity of moist air prompted him to measure the moisture absorbed by the materials of clothing and its effect on their heat transmission; and in his paper to the Royal Society on this subject there are observations on the evils of a damp climate and the dangers of sleeping in a damp bed. He was a firm advocate, too, of woollen clothing worn next to the skin, to absorb the moisture, and had no patience with the idea that it was too warm or too irritating a material for the hot weather.

An observation that, by obstructing the free circulation of air, its power of communicating heat could be reduced, led to a new inquiry. Other fluids were examined. He tells us that he had always been struck by the extraordinary capacity of stewed apples to retain their heat. Like others, he had burned his mouth with hot apple pie; and he found on experiment that stewed apples, containing actually very little solid matter, were a much poorer conductor than pure water. From this it was a simple step to obstruct the circulation of water artificially, with fragments of solid materials, and in this way he discovered the important part played by convection in the transfer of heat. With a suspension of powdered amber in an alkaline solution adjusted to the same specific gravity, he went on to make a systematic study of the convection currents in fluids on heating, and reached important conclusions.

Rumford's investigation of the propagation of heat in fluids, and particularly his discovery in these simple experiments of the important part played by convection, is one of his most valuable contributions to the science of heat. His enthusiasm for his discovery led him, however, to make extravagant claims. He convinced himself that air, water and other fluids were actually non-conductors. All heat transfer was by convection, and there could be no conveyance of heat in a fluid at rest; a conclusion which not unnaturally involved him in controversy.

Being in need of a method of comparing the amounts of light emitted by the lamps in a factory in Munich, Rumford devised an instrument for the purpose in which the positions of two lamps could be adjusted to throw equal shadows of an object on a screen. This device, which proved to be thoroughly effective and practical, was the first shadow photometer, described in Glazebrook's "Dictionary of Applied Physics" as "the earliest form of photometer capable of accurate work".

Rumford also made important observations on radiant heat. He was surprised to find that a vessel of polished brass containing hot water cooled quicker when it had a covering of linen than when it was uncovered, and was led to examine surfaces in relation to their loss of heat by radiation. He discovered that a blackened surface gave off heat far more readily than one of polished metal; and he saw at once the practical bearing of this observation, advocating polished metal dishes for serving hot food and black-painted pipes for steam heating. For the accurate comparison of the radiation from different surfaces he devised another new instrument, a differential thermometer or 'thermoscope', consisting of a glass tube with bulbs at the ends, containing air, with a 'bubble' of spirit in the tube the movement of which could be measured when the radiating bodies were presented to the bulbs.

The best known of all Rumford's experiments, made with a cannon and boring tool in the Arsenal at Munich, is so familiar that it need not be described here in great detail. It resulted in a short paper, on the source of the heat which is excited by friction, which contributed more to his scientific fame than any other part of his work. The blunt boring tool was held fixed, and entered a cavity turned in the end of a casting for a cannon; the end of the casting, separated from the main part by a narrow cylindrical neck, was enclosed in a box containing water. When the cannon was rotated by horses, after two hours and a half the friction of the borer caused the water to boil.

To the onlookers, this was a spectacular demonstration. For Rumford, the measurements and observations he made convinced him that any theory, such as the caloric theory, which attributed material properties to heat, was no longer tenable. To quote from his paper: "It appears to me to be extremely difficult, if not quite impossible, to form any distinct idea of anything capable of being excited or communicated in the manner the heat was excited and communicated in these experiments, except it be motion"; motion, that is, of the constituent particles of the heated body. He claimed no originality for this conception; but the investigation confirmed his views, held in opposition to many of his contemporaries, on the nature of heat and its relation to mechanical action; it had a decisive effect in overthrowing the caloric theory, and it paved the way for the later conception of heat as a form of energy and the measurement of its mechanical equivalent by J. P. Joule.

A good deal of controversy was aroused by Rumford's published researches. Berthollet endeavoured to explain the cannon-boring experiment on a caloric basis. Men of science in Great Britain, while they accepted his demonstration of the part played by convection in the propagation of heat, rejected his view that fluids were non-conductors. John Dalton condemned this theory, and repeated Rumford's experiments in his own way to prove that fluids could conduct. Nevertheless, he expressed high appreciation of the demonstration Rumford had given that convection currents were the main cause of the diffusion of heat in fluids. Others less discerning than Dalton saw nothing but error and even hypocrisy in his writings. A spiteful article in the *Edinburgh Review* accused him of 'borrowing' and claiming as his own the invention of the differential thermometer from Leslie. Rumford was obliged to write a "Historical Review" of his work on heat to defend himself, which is remarkable for its moderation compared with the ill-natured criticism which was levelled at him.

Rumford made mistakes, due in part to his isolation and ignorance of what others were doing at the time he was making his own experiments, and he laid himself open to criticism by the prolixity and repetition of which he was often guilty in his writings. But later generations have endorsed the opinion of Dalton, and given credit to him for what was new in his experiments and valuable in his theories on the nature of heat.

In 1802 he left England again, to settle in Paris, where he married the widow of Lavoisier. The marriage proved unhappy, and he retired to a villa at Auteuil, where he carried on his experiments. Although pressed to do so by friends, he never returned to America. He died in 1814.

# RUMFORD AS A SCIENTIST

In a Friday Evening Discourse delivered at the Royal Institution on March 27, Sir Eric Rideal gave an account of the life and work of Rumford. The Discourse was accompanied by experimental demonstrations of many of Rumford's investigations. The following account indicates the great width of his purely scientific interests.

Rumford's name is generally associated with his experiments on heat. In his day the nature of heat was a subject-matter of controversy. According to one view, heat was a material substance termed 'caloric' which, fluid-like in character, could penetrate all space, was self-repulsive, and was strongly attracted by matter. On the other hand, heat was regarded by Boyle and Hooke as a form of energy, a 'mode of motion'. Rumford's experiments in support of the energy theory were very far-reaching and embracing. The experiments on boring cannon which he carried out in Mannheim are well known.

Later, Rumford devised a simpler apparatus in which by friction between metal plates he was able to heat water surrounding the plates. He showed that the supply of heat generated in this way was inexhaustible, and he could detect not the slightest change in either the weight or specific heat of the system. It is interesting to note that his experiments led to the value of 1,034 ft.-lb. as the amount of work required to raise the temperature of 1 lb. of water by 1°, while Joule's later more precise measurements gave 772 ft.-lb. Rumford himself believed his value to be an over-estimate. He was thus the first to determine the mechanical equivalent of heat.

Rumford was the first to show that heat could travel through a vacuum, that is, in the form of radiation. He showed that radiation could take place more readily from blackened surfaces than from polished metals. He likened this radiation to the acoustic waves given off by a bell when struck, and believed that the radiation of cold or frigorific radiation, although different from the radiation of heat, yet obeyed the same laws. In 1800 Rumford repeated in the Royal Institution the experiments of Pictet on focusing cold by means of mirrors, an experiment shown here repeatedly by Tyndall. To Rumford we are also indebted for the discovery of the transport of heat by convection. He demonstrated the existence of convection currents by suspending powdered amber in dilute caustic soda of the same specific gravity as the amber. When a cylinder containing this suspension was plunged into boiling water, the convection currents rising at the sides and moving downwards at the axis were clearly seen. This experiment was published in his seventh essay in 1797, but it was not until 1834 that Prout gave the name 'convection' to this method of heat transport.

The stoves invented by Rumford for domestic heating have often been mentioned. He observed that only one-fifth of the heat generated by the fuel is radiated into the room: the rest goes up the chimney. He showed that the most effective angle between the sides and the back is 135°, and the width of the back only one-third of the front opening, the back and sides rising perpendicularly until they joined the breast of the fireplace, while the throat of the chimney was to be only about four inches wide. The increase in warmth was found to be one-half to two-thirds as compared with the traditional open fireplace.

Lo every parlour, drawing room I see
Boasts of thy stoves and talks of nought but thee.
Yet not alone my Lady and Young Misses,
The cooks themselves could smother thee with kisses.
Yes, Mistress Cook would spoil a goose, a steak,
To twine her greasy arms around thy neck.

In Paris Rumford devoted himself to improvements of the Argand burner and to the construction of a calorimeter in which the products of combustion passed through a serpentine tube immersed in a known volume of water—indeed, a very modern device. He displayed eccentricity by wearing white clothes in winter, since these radiated less heat than dark ones. In these clothes he drove around Paris in a coach with extra broad rim wheels made to his own design. Here, however, he made himself unpopular with the French scientists, especially with Laplace, with whom he also differed in views regarding surface tension.

In 1782, Argand greatly improved oil lighting by utilizing a hollow cylindrical wick which permitted air to be drawn up on each side of the wick. As in modern paraffin lamps, the burner was situated above the oil reservoir. At that time only colza and similar high-viscosity burning oils were available, and, in consequence, the height of the flame was small owing to the low rate of capillary ascent. Rumford improved the lamp by feeding the oil from a circular reservoir maintained at the same height as the wick. In 1800 the reading and lecture rooms of the Royal Institution were illuminated with the new Rumford–Argand lamps.

For testing the most suitable shade to be made, as Rumford states, "of such substances as disperse light without destroying it", he devised the candle photometer, still in use to this day. Rumford at a later date designed a portable lamp with a flat wick, and several of these are to be found in the museums in Massachusetts.

Rumford published several papers on capillarity and demonstrated for the first time the now well-known experiment of flotation of a needle at an air–water and at an ether–water interface. He concluded that liquids such as water are bounded by a pellicle on which the needle can rest, and that air retention under the needle is not the seat of the mechanism of flotation, as was suggested at the time. We now know that the molecules in the surface layer of a liquid are a little farther distant from one another than those in the bulk phase, and if they are so separated there must be net attractive or cohesive forces operating between them; thus the concept of a pellicle was not so erroneous as Laplace supposed.

# ORIGIN OF ACQUIRED DRUG RESISTANCE IN BACTERIA

By Prof. JOHN YUDKIN

Department of Physiology, Queen Elizabeth College,
University of London

## Variation in Micro-organisms

It is characteristic of micro-organisms that they readily become adapted to changes in environment. This plasticity shows itself in such ways as the development of highly specific virulence or of the ability to grow in unusual media. In undergoing this adaptation, it is sometimes possible for new strains to arise differing considerably from the original strains.

The problem of the mechanism by which such induced variations are brought about has been the subject of much speculation during the past twenty years or so. Particular attention has been given to the induction of variation by changes in chemical environment, the most notable examples being the induction of specific enzymes ('enzyme adaptation') and the induction of resistance to drugs ('acquired drug resistance'). It was while working in this field of enzyme adaptation that I described and distinguished the two most likely mechanisms of induced variation[1]. One of these was at that time called simply adaptation; a better term would be direct induction. This postulated that the change was directly induced in (potentially) all the cells by an interaction between the cells and the new chemical environment. An example of this is the induction of the ability to ferment galactose in some species of yeast which are normally unable to do this[2,3].

The second mechanism by which induced variation might be brought about was originally referred to as 'training'. This postulated the occurrence in a culture of rare mutants having the character of the new strain; the effect of the new chemical environment was entirely selective, in that the mutant cells, but not the non-mutant cells, were able to grow in it. Likely examples of mutation with selection are the occurrence of lacto-fermenting strains in *Bacterium coli mutabile*[4] and the development of strains of *Staphylococcus aureus* highly resistant to streptomycin[5]; it is still not certain, however, that these are not in fact examples of direct induction[6].

It is, of course, possible that both mechanisms may occur simultaneously, so that the new chemical environment both induces a change and selects it. Apart from this possibility, however, all workers in the field of induced variation in micro-organisms have considered only these two possible mechanisms. This is especially noticeable in the problem of acquired drug resistance in bacteria. Demerec[5,7] considers that the effect of a drug in producing resistant strains is in selecting rare spontaneously arising resistant mutants. On the other hand, Hinshelwood and his co-workers have in a large number of publications taken the view that drug resistance is similar to, and is indeed a form of, enzyme adaptation which can occur in potentially all cells. The drug induces in each cell a change in enzymatic structure which enables it to carry out essential metabolic processes, for example, by producing alternative pathways to those blocked by the drug.

The assumption universally made, that there are only two possible mechanisms by which variations may be induced in bacterial cultures, has led many workers to support one theory by criticism of the other. For example, Hinshelwood frequently points out that the theory of mutation with selection would require a number of assumptions which he considers unlikely; in consequence, the theory of direct induction is preferred as being simpler, more plausible and more economical in unproved assumptions.

The fact that the debate has continued for many years is partly because the technical aspects of the work do not lend themselves to crucial experiments which can decide the issue. In some instances of enzyme adaptation, it has been possible to induce the change in cells that are virtually not dividing, which must imply direct induction. In acquired drug resistance, however, it seems to be necessary to grow organisms for many generations, often with numerous sub-cultures, in order to induce the change. Clearly, it is possible in these circumstances for either mutation with selection, or slow direct induction, to act in producing the change.

In spite of these difficulties, I suggest that there are now sufficient experimental facts to throw doubt on both of the currently accepted theories in so far as each attempts to explain completely acquired drug resistance in bacteria. A third theory is proposed which, it is claimed, is in conformity with existing knowledge, and lends itself in some measure to deductions capable of being tested experimentally. Before, however, describing this new theory of 'clonal variation with selection', it will be profitable to examine in a little more detail some of the facts known about the phenomenon of acquired drug resistance.

## Essential Features of Acquired Drug Resistance

(1) An organism, sensitive to a given concentration of drug, may acquire a resistance to this or to higher concentrations if it is grown in the presence of the drug. Occasionally, maximal resistance is attained by one sub-culture in the presence of drug; more often, increasing resistance is achieved by sub-culturing in increasing concentrations of drug. By limiting the concentration of the drug to a value below the maximal, it is possible to attain resistance to intermediate concentrations.

(2) The apparent resistance of a culture varies with the size of the inoculum used. That is to say, the concentration of drug in which the organisms will grow will be larger if a larger number of organisms is inoculated into it.

(3) The training of the organisms to grow in otherwise lethal concentrations of drug involves not only the mere ability to do so but also an increase in the ease with which they grow. This is shown by a gradual reduction in the mean generation time and in the lag, and an increase in the size of colonies on solid media, as the process of training is continued.

(4) When a resistant culture is grown in the absence of drug, reversion to non-resistance may occur. This may be a complete reversion to a culture as sensitive as the original, or it may be a partial reversion to a lower degree of resistance. In some instances, no reversion occurs, and the degree of acquired resistance is retained. The last possibility is more likely to occur if the trained cells are repeatedly sub-cultured in the presence of the drug very many times.

## Interpretation of Essential Features according to Current Theories

Let us now examine the current explanations of these facts according to the two theories of direct induction and mutation with selection.

(1) *Graded resistance.* The fact that a culture may be made resistant to a chosen concentration of drug is in conformity with the theory of direct induction, since it is known that the degree of enzyme adaptation by direct induction is dependent on the concentration of the inducer[8]. The theory of mutation with selection must here postulate a number of step-wise mutations. Since the degrees of acquired resistance may in some instances vary by very small steps over a wide range, one must postulate many mutational steps. If one adds that such step-wise resistance may be acquired by one organism for a number of known drugs as well as no doubt for a much larger number of drugs which have not yet been examined experimentally, it can be appreciated why Hinshelwood casts doubt on the theory of mutation with selection.

(2) *Size of inoculum.* Direct induction involves the concept of opposing factors simultaneously affecting the bacteria over a period of time. On one hand, the drug stimulates the cells to produce the enzymatic adjustment necessary to by-pass the drug-blocked systems. On the other hand, the drug causes the death of continuously increasing numbers of cells. Thus the larger the number of cells inoculated into the drug-containing medium, the greater will be the chance that some will develop the necessary enzymatic equipment to grow in its presence. The theory of mutation would merely suggest that the chances of a drug-resistant mutant being present is obviously larger in a larger inoculum. It is not easy to see, however, why there should be a continuous apparent increase in the degree of resistance with increasing inocula.

(3) *Rate of growth of trained cultures.* We have seen that, in the presence of drug, cultures at first grow slowly. The rate gradually increases if they are sub-cultured into the same concentration of drug; but it often occurs that, even after prolonged training, they still grow slower in the presence of drug than in its absence. Direct induction would no doubt explain this on the basis of the increased strain put upon the organisms in developing the alternative enzymatic systems. The mutation theory simply states that the resistant mutants are slower-growing variants.

(4) *Reversion.* According to the theory of direct induction, a trained culture will or will not revert to the original sensitive strain depending on whether the induction has or has not been sufficiently 'impressed' upon the cells. After a moderate degree of training, for example, twenty passages in the highest concentration of proflavine, Hinshelwood found a rapid though incomplete reversion when cultures of *Bact. lactis aerogenes* were grown in the absence of drug[9]. However, after eighty passages in the presence of proflavine, resistance persisted during many sub-cultures in the absence of proflavine. Hinshelwood postulates that the earlier stages of direct induction involve some mechanical strain in the organism. When the strain is released by growing the cells in the absence of drug, the new enzyme systems partly regress to reach a stable level associated with the mild resistance of an equilibrium state. The later stages in prolonged induction, however, gradually produce more complex changes which stabilize the new enzyme systems, and so permit the retention of full resistance, even in the absence of drug.

The theory of mutation with selection explains reversion as being due to back mutation or the incomplete elimination of non-mutant cells, together with the selection of non-resistant cells when they are assumed to grow faster than the resistant strains. That prolonged training may result in cultures which do not easily revert is to be explained by a parallel selection of faster growing mutants with selection of the resistant mutants[9,10].

## Theory of Clonal Variation with Selection

The theory of clonal variation with selection is based on one assumption. This is that a bacterial cell, of whatever resistance, may give on division two cells with different and unequal resistance. For

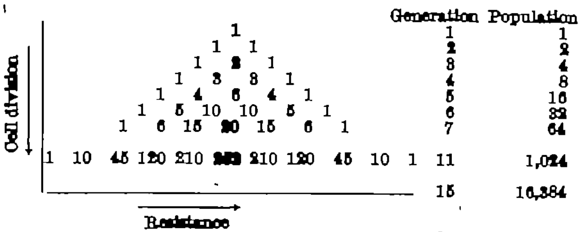

Fig. 1. Distribution of resistance in the progeny of a single cell in absence of drug

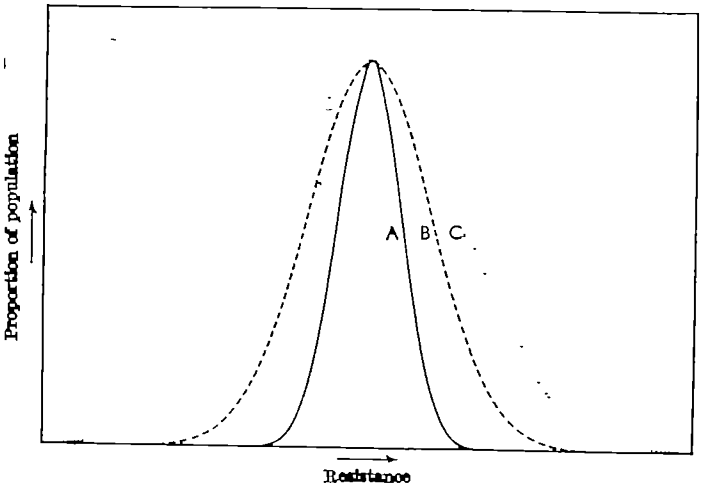

Fig. 2. Distribution of resistance in populations of bacteria grown in *absence* of drug. *A*, culture from single cell; *B*, after a few sub-cultures; *C*, after several sub-cultures—'permanent' form of distribution curve

this to occur, it is only necessary to imagine that at division the systems responsible for drug resistance are not necessarily distributed in equal amounts between the daughter cells. Within limits which will be defined later, the result is a clone of cells the average resistance of which is that of the parent cell, but with a distribution of resistance of the members of the clone around that of the parent cell.

## Model of Acquired Drug Resistance by Clonal Variation and Selection

It is reasonable to suppose that the probability of an unequal distribution of resistance in daughter cells on division is inversely proportional to the size of the inequality. That is, the dividing cell is most likely to give two equally resistant cells, less likely to give cells of slightly different resistance, and least likely to give cells of very different resistance. The resultant clone from a single cell would thus have a resistance in its members which would be of a Gaussian or similar distribution. For our simple model, however, we shall assume that division always occurs with balanced asymmetry, one daughter cell having a higher resistance by a fixed small amount, the other having a lower resistance by the same amount. Repetition of this process produces a family of cells with binomial distribution of resistance (Fig. 1).

With given conditions of composition and volume of medium and of time of incubation, the population from a single cell will be composed of cells of varying resistance, the proportions of which are distributed according to the curve *A* in Fig. 2. A small volume taken from this for inoculating into a fresh amount of medium would be likely to contain cells of the 'peak' of this curve, and not contain the rarer cells of high or low resistance. Thus an inoculum the volume of which is one-thousandth of the whole medium is not likely to contain cells the frequency of which is much less than one-thousandth of the total population. Nevertheless, the inoculum will contain some cells of higher and some of lower resistance than that of the original single cell. The population arising from this in the second volume of medium will therefore have a wider spread of resistance, something like curve *B* of Fig. 2.

During further sub-cultures, the spread will increase until it reaches a degree which we may represent by curve *C*. If we assume that we have used standard conditions of inoculum, volume of medium, time of incubation and the like in our sub-culturing, we now find that no further spread of distribution in resistance occurs in later cultures. The spread among the cells of our inoculum increases during growth to give curve *C*, but no further; it is cut short when growth ceases in the limited medium, or when the culture is discarded after an inoculum is taken. Thus the standard inoculum for subsequent cultures will contain cells of the same degree of spread. Curve *C* thus represents the sort of distribution that will exist in a culture normally being used in the laboratory.

When an inoculum is made into medium containing drug, of a concentration in which only the more resistant cells from the inoculum can grow, a situation will arise of which the earliest stages are represented in Fig. 3. In this, we see what occurs in a cell with a resistance just greater than that represented by the concentration of drug present. The drug acts as a 'bar', killing or at least preventing the growth of those cells which, because of 'clonal variation', have a resistance below that represented by the concentration of drug. As a result, only those cells to the right of the bar are able to grow, and a continuation of the process indicated in Fig. 3 can be shown to give a population of cells with a distribution of resistance shifted to the right. Eventually, after very many generations involving many sub-cultures, the shifted distribution curve will be similar in form to that of the original culture (Fig. 4).

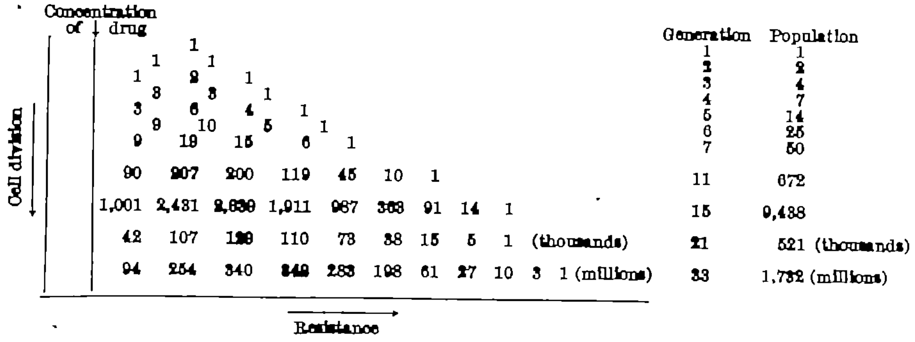

Fig. 3. Distribution of resistance in the progeny of a single cell in *presence* of drug with concentration just below resistance of the cell. Comparison with Fig. 1 shows three effects produced by the drug: (1) for a given number of generations the population is less; (2) for the same population, more generations are required, thus producing a greater spread to the right, (3) there is a very gradual shift of the peak of distribution to the right, that is, towards higher resistance

The magnitude of these effects will depend on how close the resistance of the parent cell is to the 'bar' of drug concentration

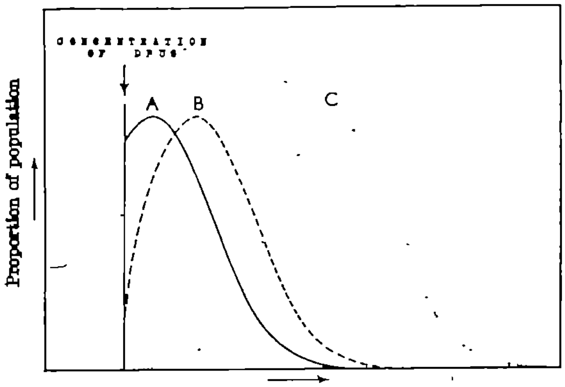

Fig. 4. Distribution of resistance for populations of bacteria grown in presence of *moderate* concentrations of drug. *A*, after a short period of growth; *B*, after a few sub-cultures; *C*, after many sub-cultures

Even the slight shift to the right in the first culture, however, will mean that an inoculum from it will contain cells of higher resistance than an inoculum from the original culture. These cells from the culture grown in drug will therefore grow in higher concentrations of drug. The culture has thus been 'trained'.

Growth in these higher concentrations of drug may perhaps give the same sort of effect as the first concentration used, and a further shift to the right may occur. With some organisms, trained to some drugs, it may be possible to repeat the process a number of times, and produce progressive 'training'.

Sooner or later a limit will be reached, beyond which 'training' cannot be induced. This represents the limit of possible clonal variation, the maximal degree of resistance possible for cells of the given strain in the given drug.

Here a new situation arises. Growth in the highest possible concentrations of drug will be limited on two sides. As well as the 'bar' to the left of the resistance curve, representing the concentration of drug, there will be a 'bar' to the right, representing the maximal possible resistance. Since cells which have maximal resistance cannot on division give cells of higher resistance, we may assume that they give either two cells of maximal resistance or one with maximal resistance and one with slightly lower resistance. In either event, there will be a tendency for cultures repeatedly grown in maximal concentrations of drug to give an increasing proportion of cells with maximal resistance, and a decreasing proportion of other cells. It can be shown that the distribution curves of cells grown in the highest concentrations of drug will have the forms shown in Fig. 5.

## Basis of the New Theory

The theory rests on the assumption that a bacterial cell might divide asymmetrically in respect of drug resistance, giving one daughter cell with less and one with more resistance than the parent cell. This is not a difficult assumption to make. It is indeed more difficult to imagine that the material upon which resistance depends, probably a system of enzymes, is always and inevitably distributed in exactly equal amounts between the two cells arising from division.

It is known that the cells of a pure culture of bacteria do not show identical resistance to a drug. All workers in this field are familiar with survivor curves in which are represented the number of cells surviving with increasing concentrations of drug. Such a curve could readily be reconstructed in the form of a distribution curve, in which would be plotted the number of cells killed rather than the number of cells surviving at each concentration of drug. We have moreover shown, in confirmation of Hughes[11], that single cells of an original culture may give populations having slightly but measurably different survivor curves. This supports the view that these single cells themselves had different degrees of resistance.

## Interpretation of Essential Features according to the New Theory

Let us now see how this hypothesis would explain the features of acquired drug resistance which were discussed earlier.

(1) *Graded resistance.* That resistance can be induced in a culture to a predetermined level, by growing the organisms in a predetermined concentration of drug, follows directly from the conception of a continuously graded resistance arising by unequal distribution at cell division.

(2) *Size of inoculum.* The dependence of the concentration of drug in which a culture will grow on the size of inoculum also follows directly from the theory, since the larger the inoculum the greater the 'spread' of resistance within the cells.

(3) *Rate of growth.* When an inoculum from an untrained culture is placed in medium containing drug, there exist two factors which result in a diminished rate of growth. The first is that only the more resistant cells in the inoculum will be able to grow. If only one in a hundred cells in the inoculum can survive the concentration of drug, it will in effect increase the number of generations to reach a given number of cells by six or seven. The second factor decreasing the growth-rate of the culture is the division of those cells of the inoculum the resistance of which is only just above that for the existing concentration of drug. When these divide, they would each give, according to the model, one cell of higher resistance and one of lower resistance. The latter or one of its early progeny would not be able to divide further, so that the result of the first few divisions of cells with 'marginal' resistance would be to give a low rate of increase of cells (see Fig. 3). If the inoculum contains a high proportion of such cells,

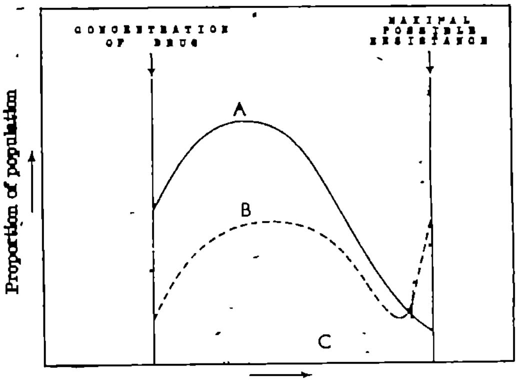

Fig. 5. Distribution of resistance for populations in bacteria grown in the presence of *high* concentrations of drug: *A*, after a short period of growth; *B*, after a few sub-cultures; *C*, after many sub-cultures

the increase in the number of cells in the culture would be smaller than in a normal culture and the *apparent* mean generation time would be increased. This point is discussed in more detail below.

As a result of these two factors, an untrained culture inoculated into medium containing drug would show a longer lag and mean generation time. If this culture is repeatedly inoculated into the same concentration of drug, there is a gradual building up of a distribution curve similar to that of the original culture, though displaced to the right. An inoculum from this will then have fewer cells which are sensitive to the concentration of drug being used, and fewer of 'marginal' resistance. Growth will therefore not be retarded so much by these two factors and 'training' will have occurred in the sense of a decrease in lag and mean generation time towards the normal.

When 'training' is complete and the organism is grown in the highest possible concentration of drug, we have the situation we described as involving the existence of two 'bars'. The distribution curve will be a narrow one, bounded on the left by the concentration of drug and on the right by the maximal possible resistance. It was suggested earlier that the latter bar might exert its effect by increasing the proportion of cells with maximal resistance. The existence of the 'bar' of drug concentration so close to that of maximal resistance must mean that cells with less than maximal resistance can very easily give rise to cells sensitive to the concentration of drug.

One would therefore expect that, for the first few sub-cultures at least, there would always be a fairly large proportion of cells which cross the 'bar' of drug concentration and do not divide further. This would mean both a prolonged lag period and an increase in apparent mean generation time. As the proportion of cells with maximal resistance increases in the cultures and in the inoculum, the lag becomes shorter and eventually normal. However, so long as a fair number of cells arise with resistance low enough to cross the 'bar', the apparent mean generation time continues to be abnormally high. Whether the mean generation time ever becomes normal will depend on the relationship between the spread of resistance at each cell division and the nearness of the existing drug concentration to that representing maximal resistance. For example, the mean generation time is more likely to continue to be prolonged if the cells of maximal resistance give on division cells of unequal rather than of equal resistance.

(4) *Reversion*. When training has occurred for a relatively short time, the distribution of resistance may not yet have reached its final form. It will be such that the proportion of cells with resistance less than the mode will be higher than the proportion with resistance greater than the mode. This proportion will be represented in an inoculum, so that a culture from it in the absence of drug will give a distribution curve which spreads farther to the left than to the right, and with a mode to the left of that of the distribution curve of the cells from which the inoculum has been taken. Depending on the organism, the drug and other factors, this shift to the left might be sufficient to make the culture measurably lower in resistance than that grown in the presence of drug. The culture would then have shown reversion.

We have seen that it may require many sub-cultures in the presence of drug for the change in the distribution curve to be completed. When this stage has been reached, there is only a small proportion of cells with a resistance to just the concentration of drug used. This is particularly true when high concentrations of drug are used, which we have suggested lead to a gradual accumulation of cells of the highest possible resistance.

Thus, the longer the cells are trained, the more permanent is the resistance acquired. This is in conformity with experimental findings.

## Some Consequences of the New Theory

A series of experiments has been planned to test some of the possible consequences of the theory of clonal variation with selection. So far as these experiments have been carried out, we have obtained results with *Bact. coli* and proflavine which conform to theoretical predictions[18].

(1) *Differences between recently isolated and older cultures from a single cell.* The theory predicts that the 'spread' of the distribution curve of resistance in a culture derived from a single cell should reach its maximum only after several sub-cultures. The first culture from the single cell, that is, should have a narrow range of resistance and should consequently not be so easily trained. Our experiments have shown that the curve of a recently isolated culture is indeed narrow and widens during a few sub-cultures, and that it is usually not possible to train the culture, except perhaps to a slight extent, until it has been sub-cultured a few times in the absence of drug. The fact that a newly isolated culture may be incapable of being trained and thus differ qualitatively from an older culture has, so far as I know, not previously been recorded. It may obviously have led to erroneous conclusions being drawn by investigators who have examined only recently isolated cultures for their ability to acquire drug resistance.

(2) *Rate of growth in the presence of drug.* One of the reasons offered by the theory for a decreased rate of growth in the presence of drug is that organisms of resistance close to the concentration of the drug used may give rise to cells of lower resistance which will then not divide further. From the distribution curve, one can determine a concentration of drug at which a high proportion of cells would have this 'marginal' resistance. If serial dilutions of the culture are made into this concentration of drug, one should find that at first only the lower dilutions, which are likely to contain some of the rarer cells of higher resistance, will show growth. The higher dilutions are likely to contain only cells of marginal resistance, and so are likely to give a considerably reduced rate of growth. The result would be that the apparent count is at first small, say after the usual 18–24 hours; later, the apparent count would be very much greater. This difference would not occur when either somewhat lower or somewhat higher concentrations of drug are used, since the proportion of cells of this 'marginal' resistance is in these instances relatively small.

Our experimental results are in conformity with these predictions.

## Discussion

The model of the method by which drug resistance may be acquired by micro-organisms has deliberately been kept as simple as possible. Nevertheless, it is suggested that the elaboration of this model in more realistic terms does not undermine its essential claim to provide a satisfactory explanation of the phenomenon.

We have seen that the assumption in the model of a fixed asymmetrical division of a cell in respect to its resistance to a drug is in fact less likely than a variable asymmetrical division, with a decreasing probability of daughter cells arising with increasingly different resistance from that of the parent cell. From a statistical point of view, however, the simpler assumption, which lends itself more easily to the construction of the model, leads to much the same conclusions.

It has also been implied that the resistance of a cell, once it has arisen from division of a parent cell, is constant. It has, however, been suggested that resistance varies throughout the life-cycle of a cell[12]. This again would not alter in any significant way the deductions from the theory. It would, however, mean that, with a given concentration of drug, cells of 'marginal' resistance would be more likely to be affected by the drug as their resistance varied during their growth. This would have two effects. First, there would be a rather more rapid shift to the right in the distribution curves of cells grown in the presence of drug than is suggested by Figs. 3 and 4. Second, those concentrations of drug which coincide with a high proportion of cells of 'marginal' resistance would affect more cells than we have suggested, and cause an even greater effect on lag and on mean generation time.

It may be argued that the theory of clonal variation has no advantages over that of mutation, and indeed that the variations in resistance which we have described are due to mutational changes in the genetic constitution of the organism. It is true that one may take the view that the difference between these two theories is only one of terminology. But it is suggested that the insistence on the use of the term mutation to describe the continuous variations of resistance which exist in a culture distorts the meaning of this word. Mutation is normally used for describing a discrete discontinuous quantum-like change occurring in a small—usually a very small—proportion of organisms. Not only are the variations we described as clonal so small as to be capable of being regarded as continuous, but also they occur in a very large proportion of the cells. Indeed, the type of distribution of resistance occurring in a culture is such that there are almost as many cells of slightly higher or slightly lower resistance than the mode, as there are cells with modal resistance; there are altogether many more cells of resistance different from the modal than cells with modal resistance. As we have said earlier, it is most improbable that there could occur the vast number of small mutations which would account for the many degrees of resistance which cells may develop for many drugs.

There is, of course, no doubt that many of the properties of micro-organisms are genetically controlled, and that these may include the capacity to undergo variation such as enzyme adaptation and perhaps the capacity to become resistant to a drug. Nevertheless, the essential feature of reproduction in micro-organisms is that the reproductive material and the somatic material are identical. The whole of the dividing cell is represented in the two daughter cells. It is therefore quite conceivable—we have earlier said it is even quite probable—that division may not be completely symmetrical and the distribution of material from the parent cell to the daughter cells not exactly equal. In so far as this material includes the enzymatic systems or other mechanisms which constitute drug resistance, the daughter cells may therefore have a somewhat different resistance from that of the parent cell.

Finally, it should be reiterated that the hypothesis of clonal variation with selection does not imply that mutation or direct induction do not play a part in producing variations in cultures grown in specific chemical or other environments. It is suggested only that this mechanism might more readily explain some of the examples of acquired drug resistance. It is tempting to suppose that the easily induced changes in bacteria and especially viruses grown in specific hosts or specific tissues are also brought about by clonal variation with selection; but it remains to be seen whether the same mechanisms underlie these and other examples of induced variation.

---

I am grateful to Dr. S. E. Jacobs and Dr. J. Mandelstam for much helpful discussion during the formulation of the views here set out, and to Miss Joan Fleming for technical assistance in the experiments. I am especially indebted to Mr. L. Bihaly, who has given me invaluable help in the statistical aspects of this work and without whose constant advice and criticism this paper could not have been written.

# NEW FELLOWS OF THE ROYAL SOCIETY

AT the meeting of the Royal Society on March 19, the following were elected to fellowship:

**Dr. J. S. Anderson**, deputy chief scientific officer, Atomic Energy Research Establishment, Harwell, distinguished for his contributions to inorganic chemistry, particularly in connexion with the chemistry of the metal carbonyls, complex salts, and non-stoichiometric compounds.

**Dr. Kenneth Bailey**, assistant director of research in the Department of Biochemistry and Fellow of Trinity College, Cambridge, distinguished for his biochemical researches on the proteins of muscle.

**Prof. H. Barcroft**, professor of physiology, Sherrington School of Physiology, St. Thomas's Hospital, London, S.E.1, distinguished for investigations respecting the blood supply to human muscles.

**Dr. J. Barker**, reader in plant physiology, University of Cambridge, distinguished for investigations on the carbohydrate metabolism of plant storage tissues.

**Dr. J. C. Burkill**, university lecturer in mathematics, University of Cambridge, distinguished for his researches in analysis, especially in the theory of integration, also for his contributions to the theory of trigonometrical series.

Dr. J. W. Cornforth, research chemist, National Institute for Medical Research, distinguished for his fundamental contributions to the chemistry of penicillin and its degradation products and to the chemistry of the oxazole group, and for the total synthesis of the androgenic hormones.

Dr. S. C. Curran, senior lecturer, Department of Natural Philosophy, University of Glasgow, distinguished for his contributions to electronic counting techniques, and for his researches upon the emission of β- and γ-rays by atomic nuclei.

C. S. Elton, director of the Bureau of Animal Population, Oxford, distinguished for his pioneer work in the field of animal ecology as founder of the Bureau of Animal Population and of the *Journal of Animal Ecology*.

Dr. O. H. Frankel, chief of the Division of Plant Industry, Commonwealth Scientific and Industrial Research Organization, Australia, distinguished for his combined genetical and cytological studies on economic plants.

Dr. E. F. Gale, reader in chemical microbiology, University of Cambridge, distinguished especially for his work on the amino-acid metabolism of bacteria and the effect thereon of penicillin and other chemotherapeutic agents.

Dr. A. G. Gaydon, Warren Research Fellow of the Royal Society, Imperial College of Science and Technology, London, distinguished for his researches on the spectra of flames, which have gone far in elucidating the mechanism of flame reactions under the most varied conditions.

Dr. A. A. Hall, director of the Royal Aircraft Establishment, Farnborough, distinguished for his contributions to the theory and design of aircraft and their equipment.

Prof. G. W. Harris, Fitzmary professor of physiology, Institute of Psychiatry, University of London, distinguished for his contributions to the physiology of the hypothalamus and pituitary body.

Sir Claude Inglis, director of hydraulics research, Department of Scientific and Industrial Research, distinguished for his pioneer work in studying hydraulics by the use of scale models, and for the application of these techniques to hydraulic problems in India.

Prof. Willis Jackson, professor of electrical engineering, Imperial College of Science and Technology, London, distinguished for his studies of the electrical behaviour of dielectrics and of the performance of transmission lines and wave-guides.

Prof. M. J. Lighthill, Beyer professor of applied mathematics, University of Manchester, distinguished for his researches in fluid dynamics, especially in non-linear problems of compressible flow, in supersonic boundary layer theory and in shock wave theory.

Dr. G. H. Mitchell, a principal scientific officer, Geological Survey of Great Britain, distinguished for his researches in palæozoic stratigraphy.

Prof. L. S. Penrose, Galton professor of eugenics, University of London, distinguished especially for his study of the factors responsible for mental deficiency and for inheritance studies in man.

A. R. Powell, research manager, Johnson Matthey and Co., Ltd., distinguished for his contribution to analytical chemistry and the chemistry and metallurgy of the rarer metals, which has led to important developments in methods for the extraction of platinum ores and the production of very pure metals.

Dr. H. M. Powell, reader in chemical crystallography, University of Oxford, distinguished for his elucidation of problems of chemical constitution by X-ray methods, especially of organo-metallic and clathrate compounds.

Lord Rothschild, assistant director of research in the Department of Zoology, University of Cambridge, distinguished for his investigations into the process of fertilization and the physiology of reproduction.

Dr. D. Shoenberg, reader in physics, University of Cambridge, distinguished for his researches in the field of low temperatures, especially upon superconductivity and the magnetic properties of metals.

Prof. T. Wallace, professor of horticultural chemistry, University of Bristol, and director of the Horticultural Research Station, Long Ashton, distinguished for his studies of mineral nutrition of horticultural crops especially in respect to diagnosis of deficiencies.

Prof. D. Whitteridge, professor of physiology, University of Edinburgh, distinguished especially for his studies of the nerves of thoracic viscera and of the external muscles of the eye.

Dr. R. van der R. Woolley, director of the Commonwealth Observatory, Australia, distinguished for his work on the formation of absorption lines and on convective processes in the solar atmosphere.

# NEWS and VIEWS

## Elihu Thomson (1853–1937)

Born in Manchester a century ago, on March 29, 1853, the son of a skilled mechanic, Elihu Thomson, pioneer in the practical applications of electricity, emigrated with his family to the United States at the age of five. After finishing his education at the Central High School, Philadelphia, he was appointed professor of mechanics and chemistry at that institution in 1876. Four years later he became chief electrician to the American Electric Company, and with Edward J. Houston founded the Thomson–Houston Company at Lynn, Massachusetts. By its merger with the Edison General Electric Company in 1892, the General Electric Company of America was formed—the largest manufacturing company of electric equipment in the world, which was to operate more than six hundred patents connected with Thomson's inventions. As director of the firm's research laboratories, Thomson discovered that the resistance of the electric arc is inversely proportional to the current passing through it, constructed the first arc-light dynamo with an automatic regulator, and was the first to use a magnetic field to move an electric arc—the principle on which magnetic blow-out switches operate. He also invented the incandescent method of electric welding, the electric watt-hour meter, and a system of colour photography. His name is given to the repulsion of a metal ring from the poles of an alternating-field electromagnet. Radiology owes to his ingenuity the first stereoscopic X-ray pictures. Thomson received medals from most of the learned societies of the world: the Rumford

Medal of the American Academy of Arts and Sciences in 1902, the Hughes Medal of the Royal Society in 1916, the Kelvin Medal of British engineering institutions in 1924, the Franklin Medal of the Franklin Institute in 1925, and the Faraday Medal of the Institution of Electrical Engineers in 1927. He died on March 13, 1937.

### Sir Isaac Bayley Balfour (1853–1922)

One of the greatest botanists of his day, Isaac Bayley Balfour was born in Edinburgh a century ago, on March 31, 1853, the second son of John Hutton Balfour. Educated at the Edinburgh Academy and University, he graduated B.Sc. in 1873, D.Sc. in 1875, M.B. in 1877, and M.D. in 1883. His medical training was interrupted by his appointment in 1874 as botanist to the Royal Society's expedition to Rodriguez Island to observe the transit of Venus, and by a visit five years later to the oceanic island of Socotra to collect plants. After studying with Julius von Sachs at Würzburg and with Anton de Bary at Strassburg, he was appointed professor of botany in the University of Glasgow in 1879, and in 1884 Sherardian professor of botany at Oxford. In 1888 he was called to Edinburgh to fill the three posts which his father, 'Woody Fibre', had held—professor of botany in the University, keeper of the Royal Botanic Garden, and Queen's botanist in Scotland—and by a remarkable coincidence he occupied these positions for the same length of time as his father had done, namely, thirty-four years. In each of the universities which he served he was destined to find a department sadly in need of reorganization. At Glasgow he introduced the practical laboratory teaching initiated by his father at Edinburgh a generation earlier. He made Edinburgh an important horticultural centre. No man knew Scotland botanically as well as he did. His most substantial published work, "Botany of Socotra" (1888), includes descriptions of some three hundred new species found in that island. While at Oxford, he persuaded the Clarendon Press to publish the ***Annals of Botany*** and also a series of translations of foreign botanical works, under his editorship. Recipient of many honours, he was elected Fellow of the Royal Society in 1884, received the Linnean Medal in 1919, and was created K.B.E. in 1920. He died at Haslemere on November 30, 1922.

### Adult Education at Leeds: Dr. S. G. Raybould

A new chair, that of adult education, has been instituted in the University of Leeds, and Dr. S. G. Raybould, at present head of the Department of Adult Education and Extra-Mural Studies and director of extra-mural studies in the University, has been appointed to fill it, with effect from October 1 next. Dr. Raybould graduated from the University of London in 1933, taking his Ph.D. in 1951, and until the end of 1935 was engaged in teaching in schools and part-time work in adult education. He then obtained an appointment in the University of Leeds as staff tutor, and in 1946 was promoted to be director of extra-mural studies, becoming head of the Adult Education Department five years later. He is at present a member of the Joint Advisory Council of the B.B.C. and of the Central Advisory Council for Education (England), as well as being vice-president of the Workers' Educational Association and deputy chairman of the Central Committee for Adult Education in H.M. Forces. Dr. Raybould's publications include a book on "The English Universities and Adult Education", a Unesco publication, and a number of articles on education.

### British Steel Castings Research Association

A new research association has been recently formed in place of the Research and Development Division of the British Steel Founders' Association, and it will be known as the British Steel Castings Research Association. Mr. J. F. B. Jackson, who, as director of research to the British Steel Founders' Association, has had the responsibility for organizing and building up its Research and Development Division since its formation in 1949, has been appointed director of the new Association. The chairman of council is Mr. F. N. Lloyd, and Mr. R. Barber is the secretary. Being derived from an organization that is already three years old and has an active programme of research in hand, the new Association starts off on a good footing. Besides the investigations being carried out at its own research station, work is being done in conjunction with the many well-equipped research laboratories and plant of industrial concerns, and it is also being sponsored in the universities. Thus during the past three years research has ranged over a wide field of steel-casting science and foundry technology, and has included an important series of projects relating to industrial health and to foundry dust suppression; in this latter connexion, work at the Dust Research Station in Sheffield, which has been in operation since mid-1951, is of particular importance. At the University of Durham and at the Imperial College of Science and Technology, London, essential basic results relating to the mechanism of the freezing of steel in refractory moulds are being obtained, and at the University of Cambridge work on the metal penetration problem and towards the improvement of surface finish in steel castings has continued since 1950. Thus, in general, the formation of this new Research Association represents an important development for a country which is renowned for its steel-making, and we may expect results which will be of vital use to the engineering industry as a whole.

### Transliteration of Cyrillic Script

The policy of ***laissez faire*** in the transliteration of Cyrillic script leads to the same name being spelt *Yachevskii* and *Jačevskij* and *Yachevsky*. This sort of thing obviously causes confusion in bibliographies, and the Royal Society has done a good service by publishing a pamphlet on "The Transliteration of Russian, Serbian and Bulgarian for Bibliographical Purposes" (from the Royal Society, Burlington House, Piccadilly, London, W.1; pp. 16; 1*s*.). The pamphlet contains tables with the recommended transliteration of Cyrillic to English and English to Cyrillic. The recommendations are agreed by the British Academy and the Royal Society and they are carefully annotated. The only disappointment (and it is an inevitable one) is that the alphabet used in English-speaking countries is not flexible enough to imitate all the sounds of the Cyrillic alphabets; and so we have to fall back on ė, ĕ, ı, ĭ, and so on. One hopes that other countries which use the same alphabet as in English will adopt the recommendations.

### Harwell Isotope School

Owing to the continually growing use of radioactive isotopes throughout the world—British sales abroad are now at the rate of four thousand consignments a year—the Isotope School at Harwell has had to introduce an additional course this year. The School was started at the Atomic Energy Research Establishment two years ago to teach the techniques of using and handling radioactive materials to scientists, medical men and industrial research workers. There has been such a heavy demand for places that an extra course will be held during July 6–31. Applications to be considered for this course should be sent to the Isotope School, A.E.R.E., Harwell, Berkshire, not later than June 8. Lectures and instruction at this School are given by members of the Atomic Energy Research Establishment staff. The school building, which is equipped with the latest apparatus, is just outside the security fence at Harwell. Students pay a fee of £40 for the course, and accommodation may be arranged for them, at an additional charge of £7 7*s.* a week, in a senior staff hostel near Faringdon.

## Decennial Supplement for 1931 for the Census of England and Wales

The Registrar General has recently published Part 3 of the "Decennial Supplement for 1931" (pp. 574. London: H.M.S.O., 1952; 70*s.* net). The tabulations for this volume were completed before the Second World War, but publication had to be postponed. The volume contains the aggregation of vital statistics (estimates of population, statistics of marriages, and births and deaths) for England and Wales during the period 1921–30. Most of the figures have already been published in the *Statistical Review*; but there are some tabulations of the less common causes of death for which annual figures are not sufficiently stable. For economy reasons no further volumes will be issued in this series.

## The Night Sky in April

New moon occurs on April 13d. 20h. 09m., U.T., and full moon on April 29d. 04h. 20m. The following conjunctions with the moon take place: April 1d. 01h., Saturn 8° N.; April 12d. 02h., Mercury 6° S.; April 15d. 16h., Mars 5° S.; April 16d. 02h., Jupiter 6° S.; April 28d. 04h., Saturn 8° N. In addition to these conjunctions with the moon, Mars is in conjunction with Jupiter on April 27d. 16h., Mars 1·1° N., and Mercury is in conjunction with Venus on April 27d. 21h., Mercury 7·2° S. Mercury is too close to the sun during April for favourable observation. On April 1 Venus sets at 20h. 40m. and is conspicuous in the western sky; it becomes a morning star after inferior conjunction on April 13, but is too close to the sun to be easily observed until near the end of the month, when it rises an hour before sunrise. Throughout April Mars sets at about 21h. and is visible for some time after sunset; towards the middle of the month it lies a little south of δ Arietis, and at the end of the month is about 4° south of the Pleiades. Jupiter sets at 22h. 10m., 21h. 35m. and 20h. 55m. on April 1, 15 and 30, respectively; it lies fairly close to Mars during the month and, as is mentioned above, there is a conjunction between the planets on April 27. Saturn rises at 19h. 35m., 18h. 30m. and 17h. 25m. at the beginning, middle and end of the month, respectively, and can be seen until the morning hours; the planet is in opposition on April 14, and throughout the month lies a little north of Spica. Occultations of stars brighter than magnitude 6 are as follows, observations being made at Greenwich: April 24d. 20h. 13·6m., $p^4$ Leon. (*D*); April 26d. 21h. 18·2m., *q* Virg. (*D*); April 30d. 23h. 58·0m., $\pi$ Scor. (*D*); *D* refers to disappearance. The Lyrids meteor shower will attain a maximum about April 21.

## Announcements

The Council of the Linnean Society of London has awarded the Linnean Medal for 1953 to Prof. P. A. Buxton, director of the Department of Entomology, London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1.

The title of reader in plant biochemistry in the University of Birmingham has been conferred on Dr. F. W. Norris, lecturer in the Department of Applied Biochemistry.

The following appointments have been made in the University of Leeds: Dr. (Mrs.) Edith Robinson, lecturer in the Department of Botany; Dr. G. Dixon-Lewis, research chemist in the Department of Coal Gas and Fuel Industries. Dr. R. Brown, reader in plant physiology in the Department of Botany, has resigned his post.

Mr. G. R. H. Nugent, Parliamentary Secretary to the Ministry of Agriculture and Fisheries, will inaugurate open days at the Electrical Research Association's Field Station at Shinfield on May 4. The Station will be open to members of the Association and other invited guests during May 6–8. Opportunity will be given of seeing work sponsored by the Association at the Poultry Research Department of the University of Reading and other adjoining stations.

The regional weather services of the Western German Republic have been grouped into a central organization, to be known as the "Deutscher Wetterdienst", with Dr. Rudolf Benkendorff as director. The address of the headquarters of the organization is Bockenheimer Landstrasse 55, Frankfurt am Main.

The Cecil Peace Prize of the Association of Universities of the British Commonwealth has been awarded for 1952 to K. H. Dawson, of the London School of Economics (at present at the Graduate School, Princeton University). The subject for the competition for 1953 is "Has the United Nations Organization been successful in carrying out the objects for which it was formed as defined in the Preamble and Chapter 1 of the Charter? Do you recommend any, and if so, what amendments in the terms of the Charter?" Essays must be sent before November 1 to the Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1, from whom further details can be obtained.

The Association of Agriculture, the Institute of Rural Life at Home and Overseas, and Seale-Hayne Agricultural College are organizing a course on "The Countryside—a Medium for Teaching", to be held at Seale-Hayne Agricultural College, Newton Abbot, Devon, during April 8–13. The course, which is designed to impart to teachers and other interested persons a better knowledge and enjoyment of the countryside, is residential and costs £5 10*s.* inclusive. Application forms and further information can be obtained from the General Secretary, Association of Agriculture, 238–240 Abbey House, 2 Victoria Street, London, S.W.1.

# THE DEPARTMENT OF PHYSIOLOGY, UNIVERSITY COLLEGE OF THE WEST INDIES

By Prof. I. F. S. MACKAY, Dr. S. J. PATRICK and Dr. P. C. FENG

THE University College of the West Indies was founded as the result of a Commission on Higher Education in the Colonies. The West Indies Committee of this Commission published a report in June 1945 and it was on the basis of this that the University College of the West Indies was planned.

For the first time in the British Caribbean, in October 1949, medical students were accepted for physiological studies. The Department of Physiology was then housed in temporary wooden buildings, where it remained until March 1952, when all the divisions of the Department were moved into new buildings. The new buildings are well lighted and ventilated and, although of simple construction, comfortable and adequate for research and teaching (Fig. 1). The detailed interior planning of the buildings and the design of the furniture and fixtures were carried out by the staff. The University has a magnificent setting of 700 acres in a valley surrounded by delightful mountain scenery.

The Department has three divisions: physiology (Prof. I. F. S. Mackay), pharmacology (Dr. P. C. Feng, lecturer in charge) and biochemistry (Dr. S. J. Patrick, senior lecturer in charge). There is a close integration both in teaching and research. The facilities of the Department, such as the animal house and workshop, are available for the three divisions. Fig. 2 shows the layout of the buildings. There is a block set aside for physiology with an extension for pharmacology, and a separate block for biochemistry. The animal house is separated from the main buildings. The lecture theatre shown in the plan is shared by the other science departments of the College, which adjoin the physiology buildings.

The Physiology Division contains a laboratory with adequate facilities for teaching forty medical students and is used both for physiology and pharmacology teaching. The usual services are provided. Each pair of students is allocated a space on the bench, which is furnished with a set of outlets for A.C., D.C., 'time', and taps for compressed air and gas (propane). There are two main research laboratories, one especially equipped for human work and one for animal work. All the necessary electrical supplies and compressed air are laid on throughout the whole Department. The extension for pharmacology houses an office and a research laboratory. There is a special dark room set aside for optical registration as well as a photographic dark room. In addition, there are the usual offices for staff which in themselves are equipped as small laboratories. The workshop is equipped to make the usual physiological equipment. The animal house, besides housing dogs and small animals, has a special research laboratory equipped for animal surgery.

The Biochemistry Division houses the departmental seminar room, which is adequate for the teaching of forty students and contains the usual projection equipment and will contain the departmental library. In this building is situated a glass and chemical store. Research facilities are provided in three main laboratories and there is a teaching laboratory to accommodate forty students.

Students are prepared for the degrees of the University of London on a "special relationship scheme". The course follows the requirements of the University of London, but as a period of six terms of study has been adhered to instead of the usual five, it has been possible to organize a more extensive practical course. The emphasis of teaching in the practical classes has been on the human aspects of physiology and biochemistry. The basic pharmacology is taught with animal experiments. The teaching of the three divisions of the Department is closely integrated, and a tutorial system where students are divided into groups of four or five is in operation. Each term these groups are re-allocated to different teachers in the Department. As the number of students in each year is small (approximately twenty) it has been possible to maintain close individual contact and supervision of their work. Science students have not yet been accepted; but teaching for applied pharmacology has already commenced.

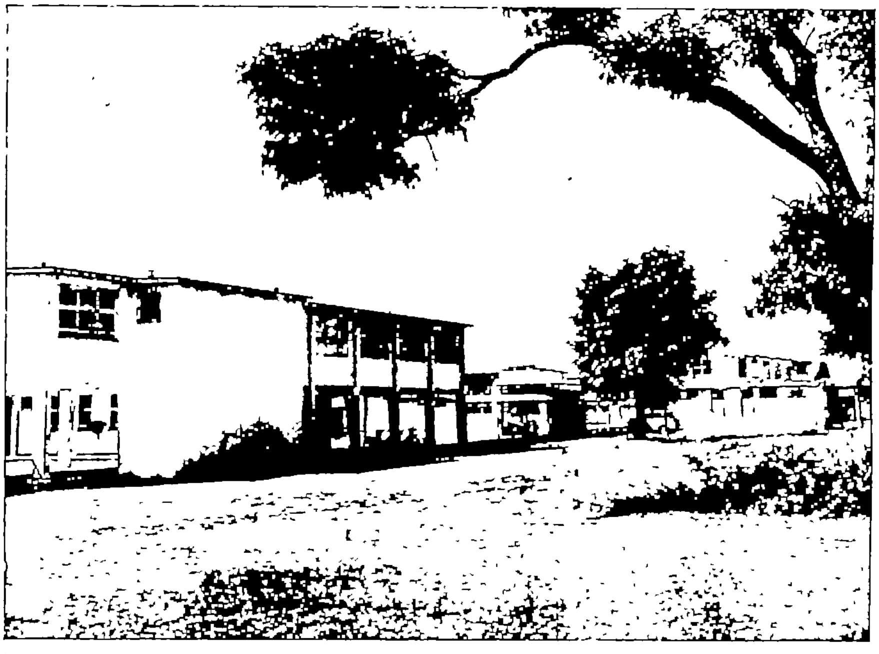

Fig. 1 Foreground left, part of the Biochemistry Division; middle distance right, part of the Physiology Division

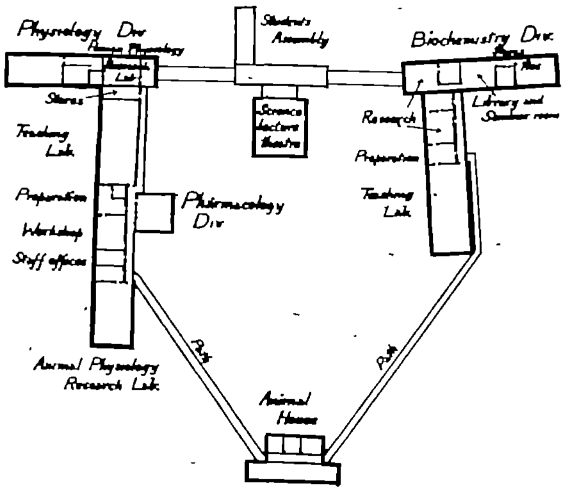

Fig. 2

The teaching of applied physiology will be undertaken when the staffing establishment has been completed.

Because of the location of the new Department in the Caribbean, it was natural that the research interests of its staff would develop in a direction where these territories offer special opportunities. Thus the over-all plan in departmental research has tended largely towards nutritional studies. Several members of the staff, in co-operation with a group from the Department of Pædiatrics from the University of Pennsylvania, are carrying out a basic nutritional survey on children and studying factors influencing nutritional status. We are pleased to report very generous assistance from the American Cyanamid Corporation, Merck and Co. and the Medical Research Council. The nutritional studies have meant an extension of the activities of the Department into relatively inaccessible parts of the island, where villages and communities are only reached after covering long distances, bad roads and surmounting such obstacles as mountain streams, etc. Those of us who have spent most of our time working in the laboratory find this field-work an interesting change. This work has provided material for biochemical studies involving an examination of the metabolism of vitamin $B_{12}$ and a study of the relationship between various enzyme systems and malnutrition. A member of the staff seconded by the Medical Research Council has been studying the intracellular enzymes of the liver and their relation to nutritional deficiencies. Another member of the staff with biochemical interests is now studying the metabolism of the coral reef and carrying out a survey of the zooplankton distribution in these tropical waters.

Jamaica is well supplied with material for the pharmacological and toxicological studies of natural products. Some work has been done on the pharmacological principles in the 'parotid' glands of the local toad (*Bufo marinus*). Studies have also been carried out on the toxicological principles of a local fruit called the ackee (*Blighia sapida*), which is a very common item in the Jamaican diet, and is supposed to be responsible for a seasonal disease called 'vomiting sickness'. This problem is under investigation with the financial assistance of the Government of Jamaica and in co-ordination with other Departments in the University. Apart from these 'Caribbean' interests, work is continuing on more fundamental physiological problems such as cardiovascular, endocrinological and intra-cellular enzyme studies. One of the pleasing factors of the University College as a whole has been the intimate and close co-operation that exists between the new Department of Physiology and those of other science and medical departments.

All the members of staff live in a housing community close to the laboratories, and a very valuable form of social life has developed in which the staff of the Department meet one evening a week on one another's verandas to read journals and discuss their current research problems. To this club are invited members from other departments with similar interests and any scientists visiting Jamaica.

In its short history the Department has been through fire and water. About sixteen months ago a fire destroyed the temporary animal house. Fortunately nuclei of the various imported animal colonies were saved and in the new permanent buildings we are returning to normal. Very anxious moments arose when flames were sufficiently close to the temporary biochemistry laboratories to cause charring of the external walls. Valuable equipment was moved to a safe distance by many willing hands. Our passage through water occurred one night when 25 in. of rain were blown horizontally by a hurricane through the laboratories. Although the roof of the biochemistry building was torn off, the damage to equipment was surprisingly small and was soon made good.

---

# THE THYROID GLAND

THE Society for Endocrinology and the Endocrinological Section of the Royal Society of Medicine held a joint symposium on "The Thyroid Gland" in London at the Royal Society of Medicine on February 25. This was well attended and covered a wide range of interests. Among the distinguished foreign visitors were Prof. Jean Roche and colleagues from the Collège de France, Paris.

The morning session was opened by the chairman, Sir Charles Harington, who gave a brief review on the development of thyroid research during the past twenty-five years. He recognized a chemical period dating from the characterization of thyroxine, which was followed by a more biological approach resulting from work on the anterior pituitary and its thyrotropic hormone. He referred briefly to recent work on the nature of the thyroid hormone and its biosynthesis. This has depended on the skilful application of chromatography and auto-radiography, particularly by Leblond, Gross, Pitt Rivers and the French team under Prof. Roche. He also dealt briefly with anti-thyroid substances. Although the goitrogens represent at present the only successful therapeutic application in this field, the theoretical importance of thyroxine analogues was mentioned.

Prof. Roche then described in some detail work carried out in collaboration with S. Lissitzky and R. Michel on the mechanisms involved in the biosynthesis of the thyroid hormone. The view was expressed that the iodination of tyrosine occurs after the incorporation of iodine in the thyroglobulin molecule. The circulating blood contains mainly thyroxine with small amounts of L-triiodothyronine; the absence of mono- and di-iodotyrosine, which occur only in the thyroid, was explained by the operation of a dehalogenase in the gland. Thyroxine is probably converted to triiodothyronine mainly in the peripheral tissues. However, the relative scarcity of triiodothyronine in the blood might also be accounted for by its more rapid excretion.

Mrs. R. Pitt Rivers outlined briefly the methods which she has recently used in collaboration with Dr. J. Gross in the identification of triiodothyronine as a significant part of the thyroid secretion. She then dealt in detail with the physiological activity of triiodothyronine, which possesses all the actions of thyroxine but appears to be about five times as active on a molar weight basis. The same ratio is obtained by different methods of assay such as goitre prevention in rats, the growth-rate of thyroidectomized rats and the minimum dose required for the control of symptoms in patients with myxœdema. The D-isomer of triiodothyronine is, however, almost inactive. Mrs. Pitt Rivers felt that L-triiodothyronine is the substance responsible for the peripheral actions of the thyroid hormone. In the discussion, Dr. G. H. Deltour reported similar results on twelve patients with myxœdema treated with triiodothyronine, and Dr. J. C. Gilliland said that triiodothyronine is more effective than thyroxine in depressing thyrotropic hormone output in the chick. Dr. S. J. Folley, on the other hand, said that he has failed to find any influence of triiodothyronine on the milk yield of cows whereas thyroxine is effective in this connexion. In reply to Mrs. Pitt Rivers, he agreed that the more rapid excretion of triiodothyronine might be of importance here.

The occurrence of post-operative myxœdema in a group of 570 patients, followed over a three-year period, has been studied by Dr. Raymond Greene. The results have been correlated with the histological appearance of the glands, and a strong correlation appears to exist between the presence of lymphoid nodules and the subsequent development of myxœdema. He said that he has formed the opinion that in the absence of lymphoid nodules no ordinary sub-total thyroidectomy will produce myxœdema, and that this complication depends almost entirely upon the state of the gland before operation. The series includes a substantial number of cases of Hashimoto's disease, but even excluding these the relationship still holds. In the discussion Prof. J. M. Yoffey stressed the possible influence of the adrenals in relation to lymphoid hyperplasia.

Mr. S. L. Hignett described a syndrome in cows consisting of thyroid enlargement and a tendency of masculinization as shown by the development of the neck muscles and the attitude of the tail. This is associated with diminished fertility and appears to present a certain analogy with the adreno-genital syndrome in man.

The last speaker in the morning session, Prof. N. F. Maclagan, gave a short account of recent work on the anti-thyroxine compounds. Most of these compounds are iodinated phenols resembling portions of the thyroxine molecule, and have aroused interest since 1946, when Woolley showed that the effects of thyroxine on tadpole metamorphosis could be antagonized by compounds of this type. The most active compound synthesized in his department was *n*-butyl 4-hydroxy-3 : 5-diiodobenzoate. This is an effective thyroxine antagonist in animals and has been tried clinically in association with Dr. Russell Fraser. It cannot, however, be administered to patients in dosages high enough to produce unequivocal anti-thyroxine effects. Results obtained in collaboration with Dr. Wilkinson and Mr. Sprott were then reported, showing that it augments the metabolic action of triiodothyronine in mice and inhibits the deiodination of L-diiodotyrosine in rats. These results support the hypothesis that the compound acts by inhibiting the deiodination of thyroxine and of triiodothyronine. Exact information about this deiodination is not, however, at present available. In the discussion, Mrs. Pitt Rivers and Prof. Roche agreed that these compounds probably are deiodinated in the animal body, although the site of this process is uncertain.

In the afternoon the chair was taken by Dr. S. Leonard Simpson, and Dr. W. R. Trotter opened with some observations on the natural history of Graves's disease as revealed by treatment with anti-thyroid drugs of the thiouracil type. He has found a significantly greater relapse-rate in patients treated for less than one year as compared with those treated for more than one year. He thought that patients who have relatively brief episodes of thyrotoxicosis are particularly liable to have one or more subsequent episodes. A further study of the patients has shown that relapses under treatment are significantly more frequent in winter and spring than at other seasons in the year. The factors concerned in this seasonal relationship are obscure, and Dr. Trotter is not impressed with the influence of psychological stress. In the discussion the influence of hot weather and of sunburn were mentioned; but no clue to this seasonal variation was forthcoming.

The next paper, on thyroid activity in the rabbit, by G. W. Harris, C. von Euler, J. Brown-Grant and S. Reichlin, was read by Prof. Harris. He described a technique employing iodine-131 which he thought gives a measure of the output of hormone by the gland over a period of some weeks. The exposure to cold and administration of thyrotropic hormone increase the rate of output, whereas confinement in the dark, thyroxine, and adrenocorticotropic hormone diminish the rate of output. This hormone is thought to produce its effect via the output of the thyrotropic hormone by the pituitary. In the discussion Dr. Russell Fraser directed attention to the need for a further analysis of emotional factors. He thought that, while fear does not cause thyroid stimulation, other emotional stimuli may do so. Dr. M. Reiss described the inhibitory effect of adrenalin on thyroid function, and Dr. Trotter expressed some doubts as to the interpretation of the release curves shown.

Dr. A. Stuart Mason reviewed methods for assaying the thyroid-stimulating hormone and presented some results on uptake of phosphorus-32 by the thyroid. He thought that this method is complementary to those involving iodine-131, as it is dependent upon hyperplasia rather than hyperfunction. Experiments with iodide suggest that its effect is produced by inhibiting pituitary secretion of thyroid-stimulating hormone rather than by action on the thyroid gland. Prof. Roche expressed his interest in the method and speculated upon its possible relation to mechanisms involving energy-rich phosphate bonds and the biosynthesis of thyroglobulin.

Dr. Russell Fraser spoke of the need for laboratory tests for thyrotoxicosis. While the diagnosis is obvious in perhaps 30 per cent of cases, more frequently it is to some extent a matter of opinion, and objective evidence of hyperfunction is of great value. He thought that measurements involving iodine-131 probably include the best single tests at present available, and, while methods involving the output of hormone as described by Prof. Harris are useful in animals, for clinical work all successful tests depend upon uptake of iodine-131 by the gland. Fortunately the uptake is usually equal to the output in the untreated patient. The method employed at the Postgraduate Medical School of London depends upon measurement of urinary radioactivity and the calculation of a *T* factor. Dr. Fraser's results show that this test is highly efficient in the diagnosis of thyrotoxicosis. It is not quite so good in cases of doubtful myxœdema, although classical cases always give low values. After treatment with goitrogens, the intake is no longer equal to the output, and the position is complicated by iodine deficiency. The test can usefully be employed three months after therapeutic doses of iodine-131.

Results illustrating the diagnostic value of serum protein-bound iodine estimation in the diagnosis of thyroid disorders were described by Dr. R. R. de Mowbray, who said that he cannot agree with some previous claims and has found high values in only 62 per cent of patients with hyperthyroidism. In hypothyroidism, results are below normal in 85 per cent of cases. High levels are seen in normal pregnancy. The overlap with normal values is a definite limitation to the usefulness of this test, but it nevertheless has its value, particularly in the case of patients intolerant of the estimation of basal metabolic rate. Mr. A. Tickner, who joined Dr. de Mowbray in this paper, then described some of the laboratory hazards of the estimation. He also reported some results with serum cholinesterase estimation in thyrotoxicosis. Although high values are frequently obtained, the estimations are of little diagnostic value.

The chairman, Dr. Leonard Simpson, wound up the symposium with a short summary, in which he said that he was particularly impressed with the application of chromatography and the use of radioisotopes in this field. As a clinician he thought that the relationship of the thyroid with other endocrine glands would repay much further study, and he gave a number of examples illustrating these relationships. He hoped that a later symposium might help to explore these other endocrine relationships.

---

# METHODS OF PLANT PEST AND DISEASE ASSESSMENT

THE meeting of the Association of Applied Biologists at Imperial College, London, on February 27 was devoted to a symposium on the assessment of plant pests and diseases. In the opening paper, Mr. E. C. Large, of the Ministry of Agriculture's Plant Pathology Laboratory at Harpenden, referred to the wealth of information[1] on plant diseases in England and Wales that had been extracted from monthly reports sent to the Laboratory since 1917, and gave an account of some of the recent surveys, undertaken jointly by the Laboratory and the National Agricultural Advisory Service, to supplement the reporting service and obtain more quantitative information on the losses caused by plant diseases throughout the country. Mr. Large described the way in which an investigation on potato blight forecasting[2], begun in 1950 in collaboration with the Agricultural Branch of the Meteorological Office, had been developed into a comprehensive survey for both outbreak dates and progress of blight. From the survey-maps and curves for the progress of blight on the foliage, taken in conjunction with the results of spraying trials at key centres, it would be possible within a few years to give reliable estimates of the mean gain, or loss, to be expected from routine protective spraying in each region of the country[3]. Disease-assessment (or, as Mr. Large now calls them, 'plant pathometric') methods applied in potato haulm destruction trials at twelve centres over a period of three years were also clearly revealing the blight conditions under which haulm destruction was, and was not, of value for the prevention of the disease in the tubers[4]. Other investigations in progress included a survey of *Epichloe typhina* attack on cocksfoot seed crops[5], now in its third year; a survey of common scab in potatoes, begun in 1952 in collaboration with the Potato Division of the Ministry of Food; and a survey of clover rot in crops of broad red and late-flowering clover, begun in 1953.

The second paper, by Dr. H. E. Croxall (N.A.A.S. Provincial Headquarters, Newcastle upon Tyne), described joint work with D. C. Gwynne and J. E. E. Jenkins in devising rapid methods for assessing the damage caused by apple diseases, particularly apple scab (*Venturia inaequalis*) and brown rot (*Sclerotinia fructigena*). Apple scab damage on the foliage might be conveniently expressed in terms of mean percentage area of the leaves covered by lesions. This could be calculated by comparing leaf samples with standard diagrams showing the appearance of individual leaves with known percentage areas covered by scab. This method was too time-consuming for rapid survey work, and from it had been derived a word-picture key in which brief descriptions were given of the appearance of branches on which the leaves had a known amount of scab damage. In a limited number of tests this method had given results of the same order as those obtained by the standard diagram method.

Similar keys had been drawn up for assessing the amount of scab blemishes on the fruit before picking and also the loss in crop due to brown rot. The results achieved so far were reasonably in agreement with those obtained by a sampling technique using standard diagrams. The possibility of correlating the mean percentage area of fruit covered by scab lesions with the grading of fruit according to the recommended grades of the Ministry of Agriculture Marketing Division was now being investigated. Methods were also being developed for giving a direct estimate of loss of value due to scab in samples of apples after picking.

Dr. R. Hull, of the Rothamsted staff (Dunholme Field Station), dealt with the records of sugar beet diseases made each year by the agricultural staff of the British Sugar Corporation under a scheme organized at Dunholme. Counts of virus yellows in sample fields were checked against yearly estimates of the acreage affected at the end of August. The disease had built up from low levels over four-year periods to peak infections in 1945 and 1949 when more than 50 per cent of the crop was infected. The weather in 1952 had been very favourable for aphid development and movement, and a severe attack of the disease developed late in the season. The losses caused by the disease were assessed by allocating an experimentally determined loss of 4–5 per cent of sugar yield for each week during which plants showed symptoms until harvest. In a bad year, such as 1949, this amounted to about 20 per cent of the sugar yield, or some 900,000 tons of sugar beet. This figure was checked by calculating a regression coefficient of yield on percentage of plants with yellows for the various factory areas. Surveys were also made of the incidence of yellows in sugar beet seed crops and of aphids in clamped mangolds in spring, as these virus and aphid sources were of importance in the initiation of outbreaks of yellows in the root crop.

In opening the discussion on the plant disease assessment papers, Mr. L. P. Smith (Meteorological Office Agricultural Branch) emphasized the need to establish the relationships between the microclimate on the plant surface and the macroclimate as defined by the recording instruments of the meteorologist. Meteorological records could already be used for forecasting potato blight, since it appeared that 75 per cent relative humidity in the air was indicative of saturation on the potato leaf surface. Advances in the application of meteorology to plant disease forecasting depended on exact definition by the plant pathologist of the meteorological factors permitting infection and on the provision of accurate means of disease assessment.

Mr. W. C. Moore (director, Ministry of Agriculture Plant Pathology Laboratory), in concluding the morning session, paid tribute to the pioneer work of Mr. Buddin. He pointed out that the United Kingdom was the only country in which full-time appointments had been made for the development and co-ordination of work on pest and disease assessment. The successful prosecution of this work depended on the co-operation of all those concerned in crop protection who were willing to give time to the surveys necessary to obtain accurate information.

The afternoon session opened with a paper on field technique in pest assessment by Mr. A. H. Strickland, also of the Plant Pathology Laboratory. Mr. Strickland recorded that routine quantitative survey work was started on some twelve pest species by entomologists in the National Agricultural Advisory Service in 1946. Initially the approach had been somewhat arbitrary—necessarily so in view of the almost complete lack of information on pest population variability within and between fields or provinces.

In 1950 four seasons work on the cabbage aphid was critically reviewed and it was realized that a much more intensive approach was needed to give reliable results on aphid abundance and crop damage. Since that time, work had been directed to assessing cabbage aphid damage accurately on an experimental plot scale and in overcoming some of the difficulties met. Two examples were given of the way in which seemingly straightforward population and yield or damage data could be misinterpreted.

It had become increasingly clear that a full interpretation of results in terms of biological activity was not in general possible on present knowledge. In view of the importance of assessing the significance of major ecological factors in relation to pest population build-up, a new pest incidence report scheme had been drawn up and was being given a trial.

Mr. F. G. W. Jones (School of Agriculture, University of Cambridge) classified the seedling pests of beet into three groups: those causing loss of stand only, those causing defoliation only, and those causing both defoliation and loss of stand. Injury caused by these pests could be assessed in terms of money, yield or, occasionally, plant population. Normally, an excess of 'seed' was sown, from which only 25 per cent of potential seedlings appeared above ground, 10 per cent having succumbed to fungal disease, 5 per cent to insect attack and 60 per cent to other causes, mainly arising from the physical properties of the soil. The cost of insecticidal seed dressings applied to beet on arable land had to be regarded as an insurance against unexpected attacks, especially where reduced seed rates were used to ease the labour problems of singling.

Field experiments had been made in which defoliation and loss of stand were produced artificially. The results of five such experiments showed clearly that beet was capable of withstanding up to 75 per cent defoliation at the four- and eight-leaf stages without suffering more than 10–15 per cent loss of yield. Re-drilling was undesirable so long as even one-half of the intended plant population remained, provided the surviving plants were fairly evenly distributed. The use of insecticides against pest attacks of moderate severity was likely to be uneconomical if the cost exceeded £3–£5 per acre.

Mr. D. W. Wright (National Vegetable Research Station, Wellesbourne) described two methods of assessing damage caused by larvæ of the cabbage root fly. The first was an estimation on the tap root of the proportion of the area injured by the larvæ; the second was by recording crop yield. These two methods showed little agreement, as the effect of a given level of root fly infestation on crop yield varied from year to year. This appeared to be correlated with the rainfall during the main period of crop growth and infestation. When the rainfall over this period was at or below average, very considerable increases in yield occurred following control of the pest. When the rainfall was well above average at this time, however, no visible or significant improvement followed control. It would thus seem that under dry soil conditions a damaged root system was unable to provide the plant with an adequate supply of water.

Losses due to this insect appeared to be greatest on crops transplanted early in the year. Crops transplanted later, and harvested in autumn and winter, were usually less affected, but with these also marked increases in yield had been obtained when the root fly was controlled.

Dr. M. Cohen (N.A.A.S., Newcastle), opening the discussion on pest assessment, stressed the need for long-term records and for relating insect attack to the physiology of the host plants. Hitherto the only records that had permitted forecasting of pest attacks had been those on leatherjacket populations. Accurate figures on losses due to pests could help to guide the intensification of control measures into those channels that would increase agricultural production most rapidly.

Prof. H. W. Miles (Wye College, University of London) considered that many lines of field work would be promoted as a result of the symposium. He directed attention to the potentialities of plants to compensate for insect injury, and pointed out that the grower must be shown by realistic figures the amount of crop loss due to pests. The need to combine economy with efficiency in pest control was specially apparent at the present time.

Dr. W. F. Jepson (Imperial College Field Station), and other speakers, referred to work on varietal susceptibility to pest damage, and pressed for a clear discrimination between degree of attack and loss of yield.

Dr. I. Thomas (Plant Pathology Laboratory, Harpenden) noted that methods of assessing plant disease loss had been initiated by research workers, but in assessing losses due to pests, methods had had to be improvised. It was essential to avoid the pitfall of ascribing losses to pests when nutrition and soil factors were primarily responsible. Dr. Thomas again stressed the need for a generous measure of co-operation and goodwill to ensure the successful development and application of methods of assessment.

R. W. MARSH

# RECENT GEGENSCHEIN STUDIES IN THE SOVIET UNION

A GOOD deal of work has recently been done, in the Soviet Union, on the Gegenschein or 'counterglow', as a result of which a fairly definite point of view has developed. In particular, the Glydén–Moulton theory is regarded as quite overthrown by mathematical analysis (Moiseyev). The Seeliger reflexion theory may account for some portion of the counterglow luminescence, but not for the main effect. Taking advantage of the extraordinarily good seeing conditions in Central Asia, Soviet astronomers have shown both by visual and by photometric observation that the counterglow is variable in shape, in intensity, and in the spatial distribution of its luminescence; that it has an emission spectrum; and that it has a parallax which places it at a distance of about twenty earth radii. This has resulted in the revival of the theory of a gaseous tail extending from the earth's atmosphere. It is thought that the tail is excited to luminescence by the solar 'corpuscular radiation' at some distance from the earth, presumably after it crosses the boundary of the 'forbidden region' (of Chapman, Martyn, Alfvén).

Some of the Russian papers on this subject[1–4] have now been translated and issued in full[5]. A short account also appears in the 1952 edition of Mitra's "Upper Atmosphere"[6], which has just become available.

According to Fesenkov[2], the tenuous exterior atmosphere of the earth may have the form of a paraboloid of revolution, convex toward the sun. Nothing is said about the mechanism by which this form is maintained; but presumably it is a combination of radiation pressure, actual escape, and very high 'bounces' of colliding molecules. The density of the gas is halved every 4·7 earth radii; but apparently, in Fesenkov's view, is uniform over any cross-section of the tail (see ref. 2, p. 500). Astapovich[1], on the other hand, describes the tail as a hollow sleeve of gas, driven off from the twilight rim of the earth by radiation pressure, like the tail of a comet.

To the recognized description of the counterglow, a completely new detail has been added by Divari[3] and Fesenkov[4], who independently discovered that, as the counterglow descends to the west of the meridian, there appears a broad pyramid of fainter luminescence connecting it to the horizon. To this phenomenon Fesenkov gave the name "false zodiacal light" (see ref. 6, p. 492).

The false zodiacal light is confined to the western side of the night sky; it does not appear in the east when the counterglow is rising. No satisfactory explanation is given for this remarkable fact. Obviously it cannot be any ordinary atmospheric distortion or superimposed luminescence, at least so long as our model of the atmosphere is symmetrical. It is necessary to postulate some atmospheric asymmetry in the evening twilight zone, and if we accept the gaseous tail hypothesis at all, we are led to suspect that the asymmetry can only be the tail itself.

In a prefatory note to his translation[5], Mr. Hope has suggested (assuming the gaseous tail really to exist) that the false zodiacal light may be explained by invoking a hitherto unconsidered fact, namely, that the earth's rotation will assist the radiant pressure of the sunlight over the evening twilight zone, but will oppose it on the morning side. The result may be that the gaseous stream is driven off mainly, if not entirely, from the evening side; Astapovich's 'gaseous sleeve' is not complete. If this incomplete sleeve is itself faintly luminous (below the actual counterglow), it will be seen against the western night sky, but not in the east.

A further suggestion is made to account for the fact that the false zodiacal light does not make its appearance before about two o'clock in the morning. This suggestion involves the idea that the fainter luminescence in the incomplete sleeve is generated by atoms or molecules, excited or dissociated in the sunlight, dropping to a lower level of excitation or recombining when they pass into the terrestrial umbra high above the earth. (Incidentally, it seems that the long cone of the earth's shadow, as a possible generator of radiation in the remote exosphere, has been little considered.)

# ABSTRACTING AND LIBRARY WORK IN THE U.S.S.R.

THREE articles on the organization of scientific information and abstracting in the Soviet Union have appeared in recent issues of *Vestnik Akad. Nauk SSSR* (22 (8, 9), 41, 46 and 80; 1952). The first of these is by A. V. Kremenetskaya and E. V. Vasilyeva, dealing specifically with abstracting (referata) and the work of the State Scientific Library. This is the largest in the Soviet Union, with about three and a half million books and other publications. Among its main objects are publicity on advanced experimental work in industry and on the achievements of Soviet science and technology, and also information on the work of other countries, especially those of Eastern Europe. Special attention is given to the provision of information in suitable form to students. In fact, the library is under the direct control of the Ministry of Higher Education; but it also has a wider range, and its services are available through two hundred and sixty industrial centres throughout the Union.

It is not clearly stated in what precise form the information is supplied—though leaflets are mentioned later—but apparently more than twelve thousand 'informations' are issued annually, manifolded and distributed to the extent of three hundred and fifty thousand copies.

Up to 1948 'subscribers' filled in questionnaires on matters in which they were interested; but this proved unsatisfactory and was replaced by subject lists and abstracts prepared by the Library. Extreme subdivision of subject-matter is not considered desirable, and many fields that were previously thus divided have now been reconsolidated. At present there are seventeen main classes in the industrial field, including nuclear physics, ultra-short-wave radio technique, tele-mechanics, etc., subdivided into more than a thousand subjects. Methods of scanning both books and journals in the library are described at some length, with special reference to the needs of technical and scientific workers, and to the relative value of so-called popular works on science and technology. 'Capitalist' publications must, of course, be carefully examined, but with a somewhat more critically selective acumen, for which various reasons are given.

More than fifty specialists are employed under an editorial staff to examine books and journals and to prepare abstracts. Nothing is said in this first article of the distinction attempted in the third article between abstracts, annotations and reviews, nor of a critical function discussed therein (see below). Up to 1941 the material collected by the Library was in the form of short 'annotations' printed on the usual library index cards, but to increase efficiency and save the time of specialists "there was a constant urge towards more detailed abstract annotations". Length of abstract naturally depended on a number of factors: material in a foreign language not readily accessible would have to be more detailed; literature from a large central publishing-house in the Soviet Union need have little more than title and date. The abstract is usually in the form of single leaflets, for which various advantages are claimed. Co-operation with other libraries and institutes, a call for suggestions and comments, and a few notes about binding, etc., conclude this first article.

The second article, by Dr. L. I. Gutenmakher, is on the mechanical aspects of information work, though it is a little indefinite. It emphasizes the rapidly accumulating and enormous dimensions of modern scientific literature, and notes the various difficult and complex problems involved.

The president of the Academy of Sciences of the U.S.S.R., A. N. Nesmeyanov, has recently suggested a study of mechanical methods for dealing with information work (*Vestnik Akad. Nauk SSSR*, 22 (2), 16; 1952), so that Stalin's doctrine—only by mechanization can Russian industry hold its place—can be applied here also. No actual machine is described; but certain general principles on which its design might be based are suggested by the author. Information in an abstract should be presented in simplest terms or elements, compressed and uniformly formulated. From one to two hundred such elements may constitute the average abstract. Analysis of material, formulation and record (abstracting) might be done through suitable rules and instructions to authors, or by special staff in one or more institutes; but the selection of information relevant to a given subject or problem should be achieved by mechanical means. Some necessary conditions are discussed; including the use of auto-cameras (photo-automatas), with examples drawn from chemical kinetics and reactions. Brief and precise systems of record are essential, with the maximum use of mathematical and other symbols and formulæ. Russian patent specifications are said to be a step in the right direction of formulation. Another problem briefly considered is that of classification, though here again the proposals are a little vague and indefinite, including a suggested use of 'addresses' and the modern technique of commutation.

The third article runs to twelve pages and deals in greater detail with abstracting (referata). The authors are K. R. Simon and G. G. Krichevskiya. The former is a well-known writer on the subject in the U.S.S.R., with numerous articles in the *Sovetskaya Bibliografiya* and other journals. A few statistics are presented to begin with. Figures for 1949 show that, in natural science, medicine and technology (engineering) only, published articles in all countries had reached 1,850,000 a year. In chemistry alone they exceeded fifty thousand a year. In the Soviet Union scientific printed publications, including books and official documents, in 1951 amounted to more than a hundred thousand. In the Russian view it is necessary to distinguish abstracts (referata) from annotations, the purpose of which is to disclose in more or less detail the subject-matter (thematics), and from reviews or criticisms. The distinctions appear a little arbitrary: it is shown later that an abstract must, of course, disclose the subject-matter, and also include a critical function.

The importance of a preliminary general survey (*obzor*) is emphasized—a summary or outline, which may also be informative or critical, although its precise nature, purpose and realization are not very clearly given. A short historical survey relates to abstracting in the Western countries (*Chem. Abst.*, *Brit. Chem. Abst.*, *Centralbl.*) and to the work of Unesco, with various points of criticism, such as the neglect of social sciences, absence of critical acumen, the complete omission of books from the general scope and, it is stated, neglect of material other than English, French and German; also a lot of unnecessary duplication. This matter of a critical function has been considered in some detail by K. R. Simon (*Sov. Bib.*, 1–3, 341; 1933).

A detailed account is given of Soviet progress in abstracting, starting with the decree of January 9, 1928, under which a Commission was established to look after "Indexes of Scientific Literature", including abstracts of all Soviet scientific publications. The original grandiose scheme, as the authors term it, of large annual volumes, could not be properly realized, and there were several defects. Many Soviet abstract publications are noted. The real requirements of an efficient abstract service are described in detail. For example, it must be a true organic system, established on a uniform plan, in accordance with a logical classification of the whole field of human knowledge, of which the main classes are indicated, including philosophy—an inclusion which may possibly be questioned.

For each division of knowledge the question arises as to its appropriate independent abstract medium, having regard to its various aspects, sub-divisions, rate of development, relevant literature, etc. It is clear that some of the main divisions cannot be provided for within the limits of one abstract publication—for example, in the sciences of philology and comparative literature—in view "of the brilliant publications of I. V. Stalin in these fields". But as regards chemistry, long experience with abstract journals has convinced the authors of the paramount need for some single but authoritative and comprehensive chemical abstract journal in the U.S.S.R., for both the theoretical and practical domains.

There is only space here to indicate the other points discussed—for example, choice of material to be abstracted, which should include not only periodicals and patents but also books, etc. (even the general press and popular magazines); linguistic scope of abstracts (what countries and languages, for there are already ten different languages in the Soviet Union itself); nature and value of the information provided, with critical evaluation; what the abstract should contain; and one or two miscellaneous considerations. W. G. Cass

# THE TURKISH EARTHQUAKE OF MARCH 18

THE recent earthquake in Turkey was not one of the greatest of that region, but it happened in a moderately well populated area and consequently the casualties have been relatively great.

Provisional readings of the Edinburgh east–west component seismogram indicate the initial time for the earthquake as 20 hr. 06 m. 16 s. G.M.T. The epicentre appears to have been near Çan in the province of Çanakkale, Western Anatolia (lat. 40° N., long. 27° E.), and the depth of focus normal. The Edinburgh Milne–Shaw seismograph has a magnification of 250, and the maximum surface waves, which are pronounced in this shock, measure 7·1 cm. amplitude (mean to extreme) on the record.

The earthquake was experienced chiefly in the Provinces of Çanakkale and Balikesir, bordering the Ægean Sea, and south of the Dardanelles. The area between Yenice and Gonen suffered severely. In this district more than six hundred houses were destroyed and many more were damaged; fire added to the damage. Çan is a centre of routes in the area, the railway lines from Çan going respectively south-east to Baya, north-north-east to Biga and Karabiga and west-north-west to Çanakkale. All these communications were interrupted and telephone and telegraph lines were down. Reports from fifty-seven villages in the epicentral area were still awaited two days after the earthquake. The shock was felt in Istanbul as strongly as any earthquake since 1906, and some apprehension was felt. Some buildings were damaged in Istanbul, including the Dolmabagtche Palace, where walls cracked and plaster fell off the ceiling of the famous reception hall. Damage has been reported from the Ægean Islands of Chios and Lesbos and the tremor was felt throughout northern Greece. The full list of damage and casualties cannot yet be assessed, but reported damage two days after the event is estimated at a quarter of a million pounds sterling, deaths at more than five hundred and injured at more than a thousand. Ankara observatory reported sixty-five aftershocks on March 19 and fourteen more to noon on March 20.

In Turkey there are annually some hundred to hundred and fifty earthquakes which are felt but which do no damage. Some others do damage only in the immediate vicinity of their epicentres; but since 1938, excluding the present shock, there have been thirteen disastrous earthquakes. These have been: (*a*) in Central Anatolia—Kirsehir-Yerköy, 1938 (19 Nisan 1938 Orta Anadolu yer deprenmesi. Ed. Paréjas and Hamit N. Pamir. Istanbul Ūniversitesi Jeoloji Enstitüsü Neşriyati, No. 5, 1940); (*b*) in Septrionale Anatolia—Erzincan (magnitude 8), December 27, 1939 (27 Birinci Kânun 1939 Erzincan yerdepremi. Ed. Parejas, I. H. Akyol, E. Altinlı. I.U.J.E.N., No. 10, 1942, also *Nature*, January 6, 1940), Erbaa-Osmancik (magnitude 7·5) 1942, Adapazari 1943, Amasya-Tosya (magnitude 7·5) 1943, Bolu-Gerede (magnitude 7·5) 1944, (*c*) in south-east Anatolia, Ceyhan-Misis 1945, Van 1945, Varto 1946, Bingöl 1949; and (*d*) in the Ægean area in which the present epicentre is situated, Dıkili 1939, Ayvacik 1944 and Çesme-Karaburun 1949. In the course of these thirteen earthquakes, fifty thousand people have been killed and a hundred thousand houses destroyed or seriously damaged. Since 1938 earthquake damage has probably cost the Turkish people 100 millions of Turkish pounds.

Tectonically, the area around the Marmara basin consists of faulted synclines, and the area adjoining the Ægean Sea consists of faulted depressions. In between these synclines or depressions there are anticlines with palaeozoic cores, 'plis de fond' or 'massifs'. The elements have been orogenically active throughout geological time, but since the end of the Néogène the general movement has been an upward (epirogenic) one. This rise is shown by the altitude of Néogène lacustrine deposits and by the quaternary terraces. To-day it is still continuing and is evidenced by the sudden changes of equilibrium between sections with faulted contact. Earthquakes accompany the faulting. Ernest Tillotson

# THORNTHWAITE FOREST, CUMBERLAND

THORNTHWAITE was one of the first forests to be established by the Forestry Commission in Cumberland, which took over eleven hundred acres of land around the Whinlatter Pass in 1920 and began planting the same year. Other land has been added from time to time, the latest acquisition being in 1947, and, since planting has proceeded continually, all ages of trees up to thirty-two years are represented. A short record of this forest has now been published by the Forestry Commission in a booklet entitled "Britain's Forests—Thornthwaite"*. The bulk of the work on the larger sections—Whinlatter, Wythrop and Dodd—was finished by 1931, and thus most of the plantations are more than twenty years old. Formerly, the young trees for planting were raised at a small forest nursery near Thornthwaite village; but nowadays they are brought from larger nurseries near the Scottish border. The forest lies three miles from Keswick, two and a half miles from Cockermouth, and twenty-three miles from Carlisle. Its greatest length from north to south is seven miles, and its greatest breadth six miles, including outlying plantations. The distance around Bassenthwaite Lake by road, which touches on most of the plantations, is eighteen miles.

Soon after the Commission commenced planting in the beautiful Lake District, there was a considerable outcry—almost inevitable, since the objectives of forestry are little appreciated in Britain. Such forestry as existed in the country a couple of centuries ago was confined to hardwoods; for many reasons, much of the Cumberland hills were only suitable for conifers.

---

* Forestry Commission. Britain's Forests—Thornthwaite. Pp. 20. (London: H.M.S.O., 1952.) 1s. net.

There are many aspects from which Thornthwaite may be examined. Perhaps one of the best known is from the south. As one approaches the well-known town of Keswick by way of the main road from Ambleside, a beautiful panorama is unfolded which includes the young forest, now covering five thousand acres. About two and a half miles short of Keswick, Bassenthwaite is seen below with the young plantations of spruce, pine and larch on the hills on either side with, at the back on the far side, Skiddaw rising to 3,053 ft.

The forest is divided into several sections bearing the local names of the areas concerned, the latest plantations dating from 1948 and 1950. The kinds of trees used are the spruces, Sitka and Norway, Scots pine, and, in small amount, *Pinus contorta* and *P. mugo*, with Douglas fir, Lawson's cypress and western red cedar. On the bottom soils and in sheltered places Japanese larch is planted. Curiously enough, the European larch does not do well in this region. More latterly, the Commission has been planting amenity belts along the Bassenthwaite roads to break the monotony of the dark conifers. The belts include the American red oak, beech, wild cherry, western red cedar, ash, birch and maple, which are seen at their best in the spring and autumn. Thinnings are being made in the older woods, from the poles of which pitprops and finer stakes are yielded, providing a return from the forest and providing work for a considerable labour force.

E. P. STEBBING

# NATIONAL PARKS IN GREAT BRITAIN

THE third annual report of the National Parks Commission* covers the year ended September 30, 1952, and notes the confirmation of the Designation Orders for Snowdonia, Dartmoor and Pembrokeshire coast national parks, and the designation, on February 12, 1952, of a sixth area, the North York moors, as well as consultations with local authorities concerning a proposed Cornish National Park. It records the view that, in spite of unpropitious economic circumstances, the design of the National Parks Act is taking shape. The claim that substantial advance has been made, however, scarcely seems to be justified by the contents of the report, although it appears that, with the exception of Snowdonia, the park authorities, in spite of handicaps due to economic circumstances, have been working with some promise and that the problems of each park are being studied by each authority with a full and proper appreciation of the intentions of the National Parks Act. The tale of administrative difficulty due to ministerial faithlessness, and the persistence of misconceptions as to the effect of designation of areas as national parks on access, is repeated from the previous report; and although the references to financial difficulties are more oblique than in the second report of the Commission there is no substantial evidence in the present report of the disappearance of the parsimony which was last year reported as hindering its educational work through the distribution of the proposed leaflet on the Country Code.

Nothing is said about that leaflet in the present report, and, although the education authorities have rendered much assistance in making the Country Code widely known to the youth of the country, it may be inferred that the Commission's own proposal is still frustrated. The most hopeful features of the report are, in fact, to be found, first, in the evidence it provides of widespread co-operation and goodwill, and, second, in the determination with which the Commission has maintained its position in the face of official indifference.

On the first, directors of education, the Railway Executive, the London Transport Executive and the Central Office of Information have helped to make the Country Code widely known, while much help has been received from local authorities, the Peak Planning Board, the Youth Hostels Association, the Ramblers' Association, the County Councils of Cornwall, Devon, Dorset and Somerset, and individual ramblers at one or more of the numerous stages—from preliminary survey to the erection of cairns and stakes or the provision of hostel accommodation involved in the establishment of the projects for long-distance routes, such as the Pennine Way, now at an advanced stage, the Cornish North Coast Path, the Pembrokeshire Coastal Path, the Thames Riverside Walk, the South Downs route and the Pilgrim's Way. The extent of such co-operation fully justifies the Commission's claim that "the designation, progressively, of the finest areas of England and Wales as National Parks signifies public recognition of the supreme quality of our landscape and of its permanent importance as a factor in the moral and physical welfare of our people, and of the need on that account to ensure that it passes inviolate to future generations". Nevertheless, such public recognition is incomplete, and whether, in fact, the long-term ideal, of which the National Parks and Access to the Countryside Act is the practical expression, is to be realized depends largely on the success of the Commission's stand in regard to administration, and the extent to which the Commission is supported in a matter which, the Commission reiterates, "is of pivotal importance not only to each individual Park but to National Parks policy as a whole".

For this reason the Commission has appended to the present report details of the administrative arrangements for the Peak District, the Lake District, the Dartmoor and the Pembrokeshire Coast National Parks. Closer acquaintance with the practical problems has only confirmed the Commission in the view it has held most strongly from the start, and which has been held by all others before it who have studied this problem—namely, that, short of an organization such as was contemplated by the Hobhouse Committee, the joint planning board, with its own whole-time planning staff, is the most appropriate and serviceable administrative instrument. Such a joint planning board should have at least a whole-time planning officer, who should be a servant of the board and independent of any of the component local authorities. The Commission regards this as a corollary to the principle that a national park should be treated as an integral unit, planned by a single authority with distinct principles and purposes in view, and it sticks to this point; although it admits that the existing arrangements, with one exception, have worked fairly satisfactorily.

---

* National Parks and Access to the Countryside Act, 1949. Third Report of the National Parks Commission for the Year ending 30th September, 1952. Pp. iv+30. (London: H.M.S.O., 1952.) 2s. 6d. net.

With regard to the exception, namely, Snowdonia, the Commission records great disappointment that no administrative system has yet been established and therefore no progress whatever made in carrying out the purposes for which the Park was designated. The course of the opposition of the three county councils to a joint board down to the statement by Mr. Harold Macmillan, the Minister of Housing and Local Government, in a letter to the County Councils dated April 25, 1952, saying that he could not doubt that the National Parks Commission was right in believing that a national park ought to be administered by one authority, has already received comment in these columns (see *Nature*, 170, 333; 1952). It would appear from the report, however, that the Minister did not receive from the Councils, in their reply of August 5, 1952, the detailed assurances which he requested as a condition of accepting, for an experimental three years, the joint advisory committee they proposed, and that they did not satisfy him that their proposed arrangements would secure the efficient administration of the Park during that period. When consulted on the replies, the Commission again had occasion to say that it could not advise the joint advisory committee method and that in its opinion the only satisfactory machinery is a Joint Planning Board; the Commission's report indicates that the Minister is again corresponding with the three Councils.

A first task of the Park Planning Authorities already appointed is the preparation of a development plan, and Mr. Macmillan has extended until December this year the period allowed to the Planning Boards of the Peak Park and the Lake District for submitting their plans. The National Parks Commission has already received from the Peak Park Planning Board a comprehensive statement of its general proposals: surveys for the development plan will be conducted so as to marshal information for future action for the preservation of the area and the promotion of facilities for open-air recreation, and particular attention will be paid to the survey of existing defacements and of advertisements, of woodland areas for preservation and of areas for planting or afforestation, of historic and interesting buildings, and of areas suitable for camp sites and parking places. The Lake District Planning Board has also outlined the main considerations on which its development plan will be based and its approach to the problems of development control in the National Park.

The National Parks Commission has been consulted upon a large and urgent volume of projected developments, principally relating to electrical development, forestry and mineral workings. Several important safeguards were included in the British Electricity Authority's Hydroelectricity Bill following discussions between the Commission and representatives of the Ministry of Housing and Local Government, the Ministry of Fuel and Power and the British Electricity Authority. In regard to overhead lines, the Commission indicates in an appendix the conditions under which it considers that capital restrictions should not be allowed to exclude relatively short lengths of underground line which is strongly desirable on amenity grounds. Consultation with the Forestry Commission has usually resulted in mutually satisfactory decisions, but a proposal to acquire and afforest about a thousand acres of one of the finest stretches of moorland scenery at Saltersgate in the area designated as the North York Moors National Park was opposed and submitted to the Minister of Housing and Local Government. The Commission records its full agreement with the policy of the Peak Park Planning Board in regard to mineral workings and endorses the view that, while quarrying in the Peak cannot be excluded, the demands of the industry should receive the closest scrutiny and that any additional areas required for limestone quarrying, over and above those already worked, should, wherever possible, be found outside the National Park. The Commission also indicates its approval of the policy adopted by the Peak Park Planning Board to ensure the protection of the amenities of the Park against unsightly and sporadic growth of camping sites, without discouraging legitimate camping for recreational purposes.

# FORMATION OF FIBRES FROM PROTEIN MONOLAYERS

By Dr. J. GORDIN KAPLAN and M. J. FRASER
Department of Physiology, Dalhousie University, Halifax, Nova Scotia

When a monomolecular film of protein at an air/water interface is compressed beyond a certain critical surface pressure it can no longer be re-expanded to its original area, due to the formation of intermolecular linkages by the unfolded film protein. As the film is further compressed, more such linkages occur, and the film 'buckles', or folds up on itself, parallel to the compressing surface (normal to the direction of compression). These regions of folding soon become visible as tiny striations running across the width of the trough[1]; continuing the compression results in the approximation and adlineation of these folds until nothing remains of the film but a solid, fibrous thread which can be picked up entire from the aqueous substratum. This process was first described by the Bordelaisian botanist, Henri Devaux[2], and is commonly called the Devaux effect[3]. It was mentioned somewhat later by Cockbain and Schulman[4].

The use of these fibres in the study of the biological properties of proteins has been demonstrated by Mazia[5], Hayashi, and the latter's collaborators[6-7]; fibres of pepsin, catalase and rabbit actomyosin have been shown to retain the specific biological activities of the unspread protein. The fibres have been shown to consist of microscopically visible 'fibrils' which appear as discrete birefringent units parallel to the fibre axis[6]. It is to these 'structural units' that Hayashi attributes the ability of his actomyosin fibres to contract against a load in the presence of adenosine triphosphate[7], despite the fact that these fibrils merely represent regions where the original film has buckled during the compression, as shown by his own electron microscopic studies[8].

In our experiments on the effect of ultra-violet irradiation of monolayers[8] and dilute solutions[9] of crystalline ovalbumin, we have reported that during the irradiation the fibres formed become increasingly thin and fragile, until finally the irradiated protein loses entirely its ability to form such a fibre. We have shown that the effect of ultra-violet light on this protein is first a non-proteolytic alteration in molecular structure, followed by a photochemical rupture of peptide linkages (proteolysis). A re-examination of our results shows that the protein has lost its ability to form a strong fibre before any appreciable proteolysis has occurred; we have thus been led to the hypothesis that a non-proteolytic structural modification causes either loss of ability to form fibres, or to the formation of fibres of altered appearance and properties. We have re-opened this question and have recorded the following qualitative observations on the effect of pre-treating ovalbumin with typical 'denaturing' agents. It should be noted that none of these agents prevents film formation; indeed, an aliquot of protein will spread to a larger area following ultra-violet irradiation[8,9], and Stallberg has found[10] that treatment in the boiling water-bath increases slightly the area to which an aliquot will spread, provided, of course, that coagulation is prevented.

If 0·01 per cent ovalbumin solutions at $pH$ 2·25 are treated in the boiling water-bath, or by ultra-violet radiation, and then spread at $pH$ 4·8 as described[8], fibres are difficult or impossible to obtain, unless a great excess of protein is allowed to become adsorbed at the interface; in this case, the fibres recovered are easy to distinguish from the controls by their fragility and thinness, and, microscopically, by the presence of short, disoriented broken fibrils interspersed in disordered granular regions in which fibrils are absent altogether. Treatment of a 0·01 per cent protein solution with concentrated urea abolished fibre-forming ability; urea treatment of a 1 per cent solution, on the other hand, led to recovery of thick, continuous, but quite fragile, fibres of totally different appearance from the controls. The former resembled a dense, white granular gel and upon drying were usually devoid of any microscopically recognizable structure and were largely non-birefringent when viewed between crossed nicols. Dialysis of the excess urea prior to spreading does not change the appearance of the fibres eventually formed, which are likewise devoid of any fibrillar substructure and after drying are unable to alter the ellipticity of polarized light.

Fibres formed from untreated protein are tough and, when wet, intensely birefringent at the 45° position between crossed nicols. Extinction occurs when the fibre axis is at right-angles to, or parallel to, the plane of the polarized light. After prolonged dehydration, birefringence is still present, but is of reduced magnitude. In this respect, these fibres are similar to those prepared by the crystal method of White and Elmes[11].

It is interesting to note that certain untreated proteins are evidently unable to form fibres at all, despite the formation of perfectly good films. We have not been able to induce insulin films to form fibres, thus confirming a remark by Wrinch[12]. Gliadin films can be made to form fibres only with the greatest difficulty and then by spreading an excess of a 1 per cent solution.

Egg albumin, although known as a difficult protein to spread[10], will unfold after eight hours on $M/15$ sodium chloride into a film the thickness of which, calculated from our results (ref. 8, Table IV), is 8 A.; these films yielded tough, elastic fibres. Urea, ultra-violet radiation, ozone and heat—agents which modify the structure of the intact molecules and eliminate many of their specific properties—either abolish their capacity to combine into fibres after adsorption at the air/water interface or cause the formation of fibres lacking the characteristic regular fibrillar substructure. Hayashi is thus correct in attributing structural significance to these so-called fibrils, since they are absent or much changed in fibres formed from protein previously treated with the usual 'denaturing' agents. The prevalent view[13] that interfacial unfolding of protein is the same sort of process as that caused by other forms of 'denaturation', differing only in that it is a more drastic form of structural modification, seems to be inconsistent with these facts. Our results rather suggest that interfacial unfolding leaves the protein molecule with a measure of two-dimensional specificity not to be found following modification with other agents. The large literature (cited in ref. 6) showing retention of biological (enzymatic, hormonal, antigenic) activity by fully unfolded protein molecules would seem to reinforce this interpretation. It is supported likewise by the work of Schaefer[14], showing definite changes in indicator oil expansion patterns in films spread from previously 'denatured' protein; it may be significant that insulin and gliadin showed expansion patterns indistinguishable from those of other proteins which had been previously modified by treatment with heat or ultra-violet radiation.

Full experimental details of the work of which this is a part are to be published elsewhere. [Sept. 2.

# OPTICAL DESIGN OF DOUBLE-BEAM SPECTROMETERS

By E. F. DALY

Unicam Instruments (Cambridge), Ltd., Cambridge

As a result of recent work on a fast-scanning double-beam spectrometer[1], which gave opportunities of examining beam balance over a range of wave-lengths while adjustments were being made to the optical system, two fundamental and rather obvious conditions were proposed which should be fulfilled by any adequate design. These were: (i) that in any plane in which the source or monochromator slits form an image the light distribution should be the same for both beams; and (ii) that in any plane in which the collimator or field forms an image the light distribution should be the same for both beams.

Non-fulfilment of the former may lead to an effect by which a displacement in wave-length occurs between the spectra of the two beams. Equality of the beams is therefore more difficult to obtain the more rapid the rate of change of energy with wave-length in the spectrum. In place of strict equality of the beams at all wave-lengths, a difference spectrum appears which resembles a differentiated version of the energy – wave-length relation for one of the beams alone.

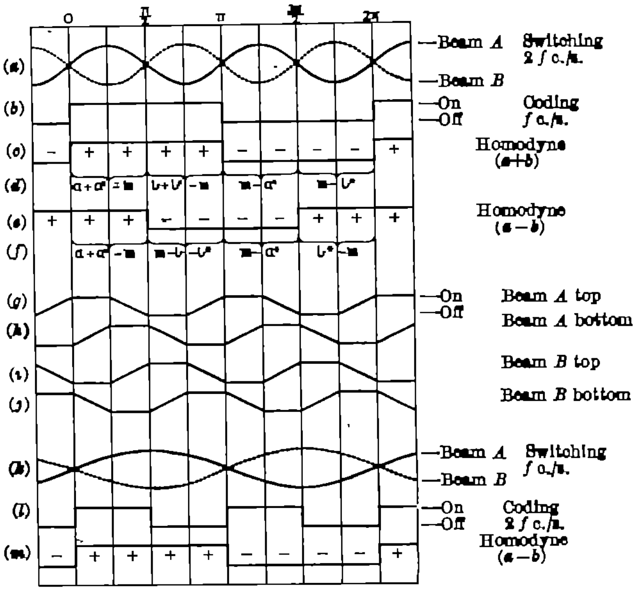
When the second condition is not fulfilled, any variations, within the radiation field, of transmission of prism and windows or of reflexion of mirrors may lead again to an inequality of the beams which varies with wave-length. This effect exhibits a rather slow change with wave-length and tends to become more pronounced as a prism transmission limit is approached.

These conditions are of fairly general application and have been used, as indicated by the following examples, in the design of a conventional recording infra-red spectrometer.

In obtaining a percentage transmission plot in a double-beam infra-red spectrometer, the null-balance method described by Lehrer[2], Wright and Herscher[3] and many others is convenient and widely used. In this, a comb-like shutter is introduced into one beam with the object of reducing the intensity of this beam until it is equal to that of the other beam containing the absorbing sample. From the position of this comb along its line of motion normal to the beam, the percentage transmission of the sample is read off. If such a comb is placed at the focus of the beam, it is clear that the first condition cannot be fulfilled, except at 100 per cent transmission, which in practice might be used for beam balancing adjustments and so conceal the effect. If the comb is used near but not at a focus, neither condition will be fulfilled. It may be noted that imperfection in the slits, in the quality of image or curvature compensation, or in uniformity of the radiation detector surface, make it possible for equal radiation powers entering different elements of the slit to produce very unequal effects.

Thus it appears that only a time-sharing type of shutter may fulfil the two conditions perfectly. We have accordingly examined the possibility of using a rotating star wheel to take the place of the comb shutter and to operate at a focus. This shutter has been designed as a wheel having twenty-four approximately triangular teeth disposed around its circumference, the depth of the teeth being 50 mm., which is thus the traverse required to cover the 0–100 per cent transmission range. It is necessary that the rotation of this wheel should be synchronized with the beam-switching mechanism, and also that several complete revolutions of the wheel should take place during one beam-switching cycle, to avoid errors arising from eccentricity or imperfections of the teeth. Such a shutter, of correct tooth form, will have negligible error on small slit-widths but will be subject to the averaging and end errors, arising at large slit-widths, which are common to both the space-sharing and time-sharing types of shutter.

A second application of the conditions arises in the adaptation of the principle of the multiple-pass monochromator described by Walsh and others[4-6] to a double-beam spectrometer. The design which we have adopted is based on a beam-switching mechanism consisting of continuously rotating sector disks giving a switching frequency of $2f$ c./s. and a coding shutter (the equivalent of the chopper used in Walsh's arrangement) operating at $f$ c./s. and synchronized with the beam switch. Two homodyne detectors, one synchronized with the coding shutter and one $\pi/2$ out of phase with it, give outputs from which the stray light components have been eliminated and which correspond to the sum and difference of the two beams respectively, the sum output being used to control recording speed and the difference output to control the null-balancing and recording servo-mechanism.



Phasing relations between beam switch, coding shutter and homodyne gates are indicated by the accompanying chart. For mechanical reasons the beam switch gives a gradual change-over from beam $A$ to beam $B$ and back, as shown at ($a$), while the coding shutter gives a rather rapid change-over indicated at ($b$). Homodyne detector gating signals are shown in ($c$) and ($e$), + indicating passage unchanged and − inversion of the signal. Using a notation in which $a$ represents the intensity of the wanted component of beam $A$ and $a^*$ the stray component, $b$ the wanted component of beam $B$ and $b^*$ the stray component, and $m$ the mean intensity over the cycle, the homodyne outputs are shown by ($d$) and ($f$), the D.C. output-level being proportional to the algebraic sum of these over one complete cycle.

It is necessary, in order to fulfil the optical conditions, that the duration of irradiation of each element of the collimator should be the same for beams $A$ and $B$. That this is the case may be inferred from ($g$) to ($j$), in which the intensities of illumination of the top and bottom halves of the collimator are indicated diagrammatically for both beams. When the illuminated portions occurring in the second quadrant are subtracted from those occurring in the first quadrant, it is seen that those parts during which the illumination is changing cancel out, leaving full illumination of the collimator by beam $B$ for $\frac{1}{4}$ cycle to be subtracted from full illumination of the collimator by beam $A$ for $\frac{1}{4}$ cycle. It is evident that the cancellation of stray light will be efficient, since the beam switch is in the same phase during the two quadrants for which signals are subtracted in the homodyne detector.

Mechanical considerations might suggest that operation of the beam switch at $f$ c./s. and the coding shutter at $2f$ c./s. would be preferable; but it will be seen that such a system, though otherwise practicable (see ($k$) to ($m$)), does not fulfil the optical conditions, the net effect being that in the $a-b$ homodyne case the top half of the collimator is used for one beam and the bottom half for the other. A system similar to this but using a reciprocating beam switch mechanism has been described by Rochester.

I am indebted to the directors of Unicam Instruments (Cambridge), Ltd., for permission to publish this communication. [Sept. 18.

# CLASSIFICATION OF MYXOMA AND FIBROMA VIRUSES

By Prof. FRANK FENNER
Australian National University, Canberra

INTEREST in the classification and nomenclature of the animal viruses has been stimulated by the discussions at the Fifth International Congress of Microbiology at Rio de Janeiro[1]. The occurrence in Australia during the summer seasons of 1951 and 1952 of severe and widespread epizootics of myxomatosis among the wild rabbits[2] has redirected attention to this virus, and it is appropriate to consider the question of its classification, that is, its relationship to other animal viruses.

Eight criteria to be applied in classifying animal viruses were laid down by the virus sub-committee at Rio de Janeiro. We will discuss these in turn, and see if light can be thrown on the classification of myxoma virus in this way.

(1) *Morphology and method of reproduction.* There is general agreement that morphology and size are among the most important features in the determination of the broad (generic) relationships of the animal viruses. Stained smears of the elementary bodies of myxoma virus[3] and fibroma virus[4] showed that they resembled vaccinia virus in their size and shape.

Only one study[5] of myxoma virus with the electron microscope has been published, and no electron micrographs of fibroma virus have been printed. However, recent work[6] extends our knowledge of the morphology of these viruses. The elementary bodies of myxoma virus were found to measure 286 μμ × 230 μμ by Farrant and Fenner[6], and 287 μμ × 233 μμ by Ruska and Kausche[5], dimensions almost the same as those of vaccinia virus elementary bodies photographed under the same conditions. More careful examination of metal-shadowed elementary bodies of myxoma virus revealed the central 'condensation' observed also in vaccinia and fowlpox viruses. Treatment with pepsin produced the appearance of a clearly defined central body which resisted peptic digestion[6]. Similar results have been obtained after pepsin treatment of vaccinia[7] and fowlpox[8] viruses. Bang[9] found that, in electron micrographs of sections of chick chorio-allantoic membrane, elementary bodies of myxoma virus were indistinguishable from those of vaccinia virus[10].

It is clear that myxoma is almost the same size, and has the same external shape and internal architecture, as vaccinia and fowlpox viruses.

A few exploratory investigations have been made of the mode of reproduction of vaccinia virus. Infectivity titrations at frequent intervals during the first forty-eight hours, using the chorio-allantoic membrane of developing chick embryos[11] and tissue cultures of the rabbit skin[12], have been interpreted as demonstrating that the same sequence of events occurred as had been found with bacterial viruses[13] and influenza virus[14]. There was a sharp reduction in the amount of infective virus immediately after infection, and no increase could be detected for about eight hours[11] or ten hours[12]. Briody and Stannard[11] observed another sharp rise sixteen hours after the initiation of infection. Preliminary experiments[15] with myxoma virus grown on the chorio-allantoic membrane gave results very similar to those obtained with vaccinia virus. Less than 1 per cent of the inoculated virus could be recovered from the membrane during the first six hours after inoculation. Demonstrable unabsorbed virus and losses during the preparation of the membrane suspension accounted for only 8 per cent of the 'lost' infectivity, so that with myxoma virus also there is an unexplained disappearance of infective virus during the first few hours after inoculation. Eight hours after inoculation there was a slight increase in the infective titres of the membrane suspension, of doubtful significance, and between the sixteenth and twentieth hours the titre increased a hundredfold. The results with both vaccinia and myxoma are too fragmentary to allow any definite conclusions to be drawn concerning their mode of reproduction, but so far no inconsistencies in the behaviour of the two viruses have become apparent.

Studies have also been made of the life-cycle of vaccinia virus in the chorio-allantoic membrane of the chicken embryo with the electron microscope[10,15,16]. The most important conclusion derived from these investigations is that the nucleus probably plays an important part, for the earliest virus particles appear to form at the nuclear wall. No reports have been published of the appearances of cells infected with myxoma virus.

(2) *Chemical composition and physical properties.* The only chemical study made of myxoma virus is that of Balls *et al.*[17]. They found a peculiar lipoid (not cholesterol) in the centrifuged deposit of an elementary body preparation. The nitrogen, phosphorus and lipoid content of this sediment were much the same as the corresponding figures for vaccinia virus and the Rous sarcoma virus.

Schlesinger and Andrewes[18] carried out filtration and centrifugation experiments with fibroma virus. They found that the diameter of the virus, estimated by filtration through graded membranes, was about the same as that of vaccinia (125–175 μμ) and by centrifugation 126–141 μμ. The specific gravity of the virus was estimated at 1·3.

(3) *Immunological properties.* Myxoma and fibroma viruses are closely related antigenically[19], and myxoma virus, which has been investigated in some detail[20], is antigenically complex, having at least two soluble antigens. Neither virus appears to be capable of agglutinating red blood cells[21].

There is no immunological relationship between myxoma virus and vaccinia virus, and no antigenic comparisons have been made with other viruses of the same size and shape.

(4) *Susceptibility to physical and chemical agents.* One of the few satisfactory studies of heat-inactivation of animal viruses is that of Bronson and Parker[22] with myxoma virus. Because no comparable data were available on other viruses of the same size and shape, similar investigations were carried out with a number of viruses of the pox group[23]. Some of the results are summarized in the accompanying table. They are expressed as the time required to inactivate,

TIME (IN MINUTES) REQUIRED TO REDUCE THE INFECTIVE TITRE OF SUSPENSIONS OF VIRUS IN NORMAL RABBIT SERUM FROM $10^7$ TO ZERO, BY HEATING AT 55° C. THE RESULTS OF DUPLICATE EXPERIMENTS ARE SHOWN

| Myxoma | Fibroma *O.A.* | Vaccinia | | Cowpox | Ectromelia | Fowlpox |
|---|---|---|---|---|---|---|
| | | Gillard | Mill Hill | | | |
| 24, 25 | 11 | 82, 74 | 125, 155 | 62, 53 | 48, 42 | 54, 45 |

by heating at 55° C., suspensions of a number of viruses in normal rabbit serum, the initial concentration in all cases being $10^7$ infective particles/ml. The figures shown were determined by extrapolation of the straight lines obtained when the infectivity (on a $\log_{10}$ scale) was plotted against the time of heating. There was some variation between different strains of vaccinia virus; but myxoma and fibroma viruses appeared to be more susceptible to inactivation by heat than any of the other viruses tested.

Andrewes and Horstmann[24] regard resistance to ethyl ether as a property which might be useful in the classification of viruses, since in many cases it runs parallel with distinctions made on other bases. We[25] were able to confirm their observations of the sensitivity of myxoma and fibroma viruses, and the resistance of vaccinia, fowlpox and ectromelia viruses to ethyl ether. However, when a number of viruses were tested for inactivation by certain surface-active agents (sodium lauryl sulphate, sodium deoxycholate, and saponin)[26], myxoma virus was found to resemble fowlpox, vaccinia and ectromelia viruses and to differ from a number of other viruses in the high degree of resistance it showed to these chemicals.

(5) *Natural methods of transmission*. The natural method of transmission of fibroma virus is not known, though it may well be mechanical carriage by insect vectors[27]. Myxomatosis may be transferred by contact[28] or by exposing rabbits to a virus-containing mist[29]; but in Nature transmission is effected principally by insect vectors[2] and, at least in the most important vector, the mosquito, is purely mechanical in nature, being due to contamination of the mouthparts by virus in the skin lesions[30]. The modes of transmission of myxomatosis are quite similar to those of fowlpox[31].

(6) *Host, tissue and cell tropisms*. Both myxoma and fibroma have a limited host-range, rabbits of the genus *Sylvilagus*[32,33] and *Oryctolagus*[32,34], the developing chick embryo[35,36] and the developing duck embryo[37] being the only susceptible hosts. While vaccinia has a very wide host range, other characteristic members of the pox group (variola, mousepox) have a restricted host range.

Both myxoma[38] and fibroma[39] cause a generalized disease in the laboratory rabbit, which is characterized by a primary lesion at the site of inoculation of the virus and secondary localization in the skin about a week later[40]. This train of events resembles closely that encountered with mousepox[41], and vaccinia in rabbits[42].

(7) *Pathology, including formation of inclusion bodies*. The strains of myxoma and fibroma viruses isolated from naturally occurring cases induce at first proliferation in the cells which they attack, followed later by necrosis. A variant strain of fibroma virus (*IA*) causes inflammation and necrosis from the outset. While these properties have led many investigators in the field of oncology to study the myxoma and fibroma viruses, they cannot be considered as of much importance from the point of view of taxonomy. Vaccinia and fowlpox viruses also cause hypertrophy and hyperplasia of infected cells[43].

Both myxoma and fibroma viruses produce acidophilic intracytoplasmic inclusion bodies in the epithelial cells of infected skin lesions[44,45], and in the ectodermal cells of the chorionic membrane of the chicken embryo[46], and in this they resemble the viruses of the pox group.

(8) *Symptomatology*. There is little left to be said of symptomatology which has not been mentioned earlier. Virologists concerned with the animal viruses are doubtful whether it has much importance in classification of these viruses.

## Summary

The points of resemblance of myxoma virus and accepted members of the pox group of viruses are so numerous, and the detailed morphological similarities of the elementary bodies so great, that the conclusion is inescapable that myxoma virus (and fibroma virus) should be included within the pox group. Of all the characters examined, myxoma and fibroma virus differ from viruses like fowlpox and vaccinia only in their sensitivity to ethyl ether. It would appear more logical to doubt the absolute importance of this property than to base the exclusion of myxoma virus from the pox group upon it.

### A Fast and Efficient Neutron Detector

MEASUREMENTS of the variation of neutron cross-section with neutron energy have been made at Harwell using an electron linear accelerator pulsed neutron source, and a time of flight spectrometer technique[1]. In these measurements a boron trifluoride proportional gas counter was used, and in order to obtain an adequate efficiency of detection it was necessary to use a rather large gas volume. This counter limited the neutron energy resolution in two ways: at low neutron energies (10 eV.) the counter length of 50 cm. was the main indeterminacy in the neutron flight distance, and at high neutron energies (keV.) there was the additional and larger indeterminacy in the ion collection time in the counter.

Various alternative detection methods have been tried with the object of combining a more rapid response with increased neutron capture, and it now seems necessary to adopt some form of scintillation detector containing boron[2,3]. In the present investigation, the most promising substance tried was borazole[4], $B_3N_3H_6$. Solutions of borazole in *para*-xylene, with *para*-terphenyl added to a concentration of 5 gm. per lit., have the following useful properties: (1) processes of exciton transfer in xylene are not quenched by the borazole; (2) scintillation pulses obtained by irradiation with polonium alpha-particles are proportional in intensity to the molar concentration of xylene; (3) scintillation response time is less than $10^{-8}$ sec. Thus, for example, an equimolecular solution of borazole in xylene is a detector with a boron density increased by a factor of 400, and a response time shortened by a factor of 100, when compared with the boron trifluoride counter.

I am indebted to Mr. W. L. Borrows, of the Admiralty Research Laboratory, Teddington, for the preparation of the borazole. I also wish to thank Dr. K. W. Bagnell for information about borazole and guidance on boron chemistry, and to acknowledge the help and encouragement given by Dr. E. Bretscher and Mr. G. N. Harding.

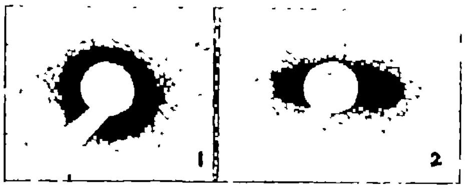
### Low-angle X-Ray Diffraction of Bone

THE study of diffuse scattering of X-rays at low angles has been used for evaluating the size of crystallites and of particles[1]. We have applied this technique to bone tissue in order to study the arrangement of hydroxylapatite crystallites in this structure.

Earlier wide-angle investigations have shown that the *c*-axis of the hydroxylapatite unit cell is parallel to the fibre axis of the collagen[2]. This arrangement can also be demonstrated in *in vitro* experiments[3].

Longitudinal- and cross-sections of compact bone from several animals were prepared by grinding. The sections were about 0·1 mm. thick. Both wide-angle and low-angle diffraction patterns were registered simultaneously on films placed at different distances from the sample. Nickel-filtered copper radiation was used. In Fig. 1 is shown the low-angle diffraction pattern from a cross-section of bone, and in Fig. 2 the pattern from a longitudinal section (longitudinal axis of bone is vertical). The wide-angle and low-angle diffraction patterns from cross-sections showed no appreciable orientation, but in the case of longitudinal sections the low-angle scatter showed marked equatorial orientation, and the 002 reflexion in the wide-angle pattern showed meridional intensifications. In bone, therefore, the hydroxylapatite crystallites are elongated with their long axes parallel to the collagen fibres.



Estimations of the short dimension of the crystallite (the width) gave an approximate diameter of 60–80 A. When estimating the long dimension of the crystallites, the small-angle meridional diffraction of the collagen interferes. Several orders of a fundamental spacing of about 660 A. were obtained from the intact bone tissue. The long dimension is estimated to be about three times the width.

Full details of this work will be published elsewhere.

### Shadow Microscopy for Measurement of Height

THIS note describes a simple optical microscope shadow technique which permits measurement to be made of the heights of small objects such as particles, spores, steps on surfaces, etc., and also reveals qualitative surface topographical features in a striking manner. This is an optical analogy to the familiar metallic shadow-casting method which is used with electron microscopes. I have used it with powers up to that of a 4-mm. objective.

When an object on a specially prepared slide on a microscope stage is illuminated by a parallel light pencil at incidence near to grazing, then a reasonably sharp long shadow is cast on to the slide. Provided the object is appreciably larger than the wave-length of the light used, then the ratio of shadow-length to object-height is the tangent of the angle of incidence. For grazing angles of 5° and 3° the respective lengths

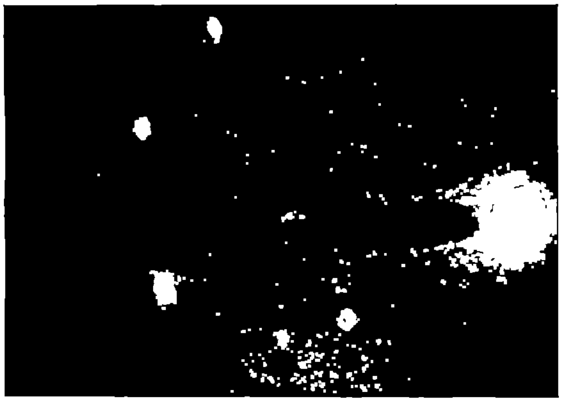

Fig. 1. Lycopodium and *Trichoderma viride* spores: microscope, × 240; shadow, × 12; total, × 2,900. (Reduced in reproduction to about a half)

of shadows are some 11 and 19 times the object height. Thus with a microscope magnification × 500, the magnification of height in a shadow at incidence slightly less than 3° has the astonishing value of × 10,000. Such magnifications are not always necessary, but are available if needed.

A bright parallel beam of some 1 mm. diameter is projected on to the object by a lens stopped down with an iris. The angle of incidence, and thus the shadow-length magnification, is adjustable by raising or lowering the illuminating lens. The angle of incidence need not be measured, as the introduction into the field of view of approximately spherical particles of measurable diameter secures calibration for any particular illumination set up, irrespective of the power of the microscope objective used. Thus any convenient spherical particles can be used for establishing the shadow magnification, for then the visually observed diameter is equal to the height. Alternatively, the ratio of length to width of shadow gives the magnification ratio.

Lycopodium powder is quite suitable for this purpose as the particles are reasonably spherical and easily measured.

An essential basic feature of this technique lies in the correct preparation of the surface receiving the shadow. This will usually be either (*a*) a slide to receive small objects such as particles, filaments, grains, crystals, biological objects, etc., (*b*) the surface of, say, a crystal, metal or some other extended object with topographical features on it. The surface receiving the shadow must be a reasonably flat fine-grain scattering surface. For example, if lycopodium be scattered on to a glass slide, shadow-casting illumination will produce no shadow at all. The system behaves like dark-ground illumination pushed to the limit and one sees the brightly illuminated particles, without any shadow, for no light scatters up to the microscope from the polished glass surface. A number of suitable surfaces have been developed, but by far the best is to deposit on a slide a layer of silver and then expose this to aqua regia vapour, which converts it into a cloudy white matt fine-grain deposit, capable of producing shadows of high definition when particles are placed on it. The fine grain is the important point. To examine the topographical features of, say, a crystal, this is first coated with silver and then exposed to the aqua regia vapour, thus creating the matt surface *in situ*. The dark shadows for particles will often be bordered by brighter diffraction edges. By photographing on to a reasonably contrasty plate a sharp clean finish to the shadow obtains and both shadow-length and -width can readily be measured.

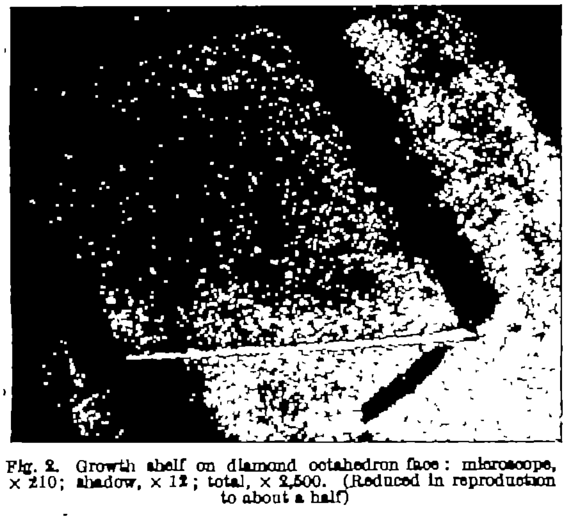

Fig. 2. Growth shelf on diamond octahedron face: microscope, × 210; shadow, × 12; total, × 2,500. (Reduced in reproduction to about a half)

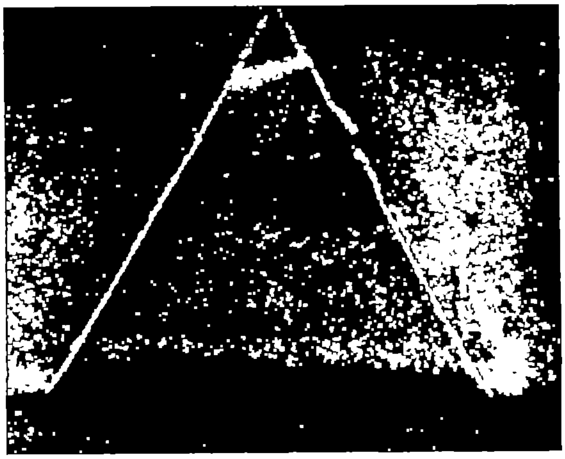

Fig. 3. Hollow growth trigon on diamond octahedron face: microscope, × 210; shadow, × 12; total, × 2,500. (Reduced in reproduction to about a half)

Typical applications are shown in the accompanying figures. Fig. 1 shows spores of *Trichoderma viride* and a lycopodium particle using × 240 magnification in the microscope. The magnification in shadow is × 12, which makes the total effective magnification of height about 2,900 in the shadow. Fig. 2 shows at × 210 and shadow magnification at × 12 growth shelves on a diamond octahedral face. A further example in which total shadow magnification is also × 2,500 is shown in Fig. 3, which is a hollow trigon depth about 3 μ. When such an object rotates, the shadow of a ledge sweeps round, vanishing when the ledge is parallel to the direction of the incident light pencil. On further rotation the front of the ledge then becomes a brightly illuminated wall and there is still no shadow.

It is clear that this shadow technique has wide applications. An experimental study is being made now of the lower limit of height which will reveal a detectable shadow. It is to be expected that diffraction will confuse the situation considerably for very small particles and this is under examination.

This is largely a technique for studying features above the general level, that is, particles, hillocks, shelves, elevations, etc., rather than one for looking into hollows, unless in fact the hollow has a much larger flat bottom extension than its height. In some cases contrast is decidedly improved by plane polarizing the illuminating beam, largely through cutting out scatter from the object.

It should be noted that the shadows of single particles may at times be forked or show a multiple structure, revealing thus unsuspected peaks or valleys on the surfaces of the particles. The patterns given by transparent crystallites require to be interpreted with reference to the possible transmitted light which can appear within the centre of the shadow.

Quite apart from the height-measuring capabilities of this system, the grazing illumination on the fine-grain matt surface turns out to be a new vivid technique for revealing topographical features by creating new contrasts. It is, of course, a modified form of controlled and heightened dark-ground illumination. One sees far more by this technique than by direct microscopy.

## Polarized Ultra-Violet Absorption of Anthracene

Theoretical calculations of $\pi$-electron states in aromatic molecules give values for three important properties of spectral transitions. These are the wave-length, intensity and polarization of the band systems which correspond to jumps between the calculated states.

Finding the polarization of observed band systems to check the calculations is more difficult than finding the wave-length and intensity, and has not often been attempted in aromatic hydrocarbons except in the weakest band systems, for which quite thick crystals give measurable optical densities[1,2]. However, by working with the thinnest sublimation flakes that could be transferred without shattering to a silica plate, we have now measured the polarizations of some stronger systems in the near ultra-violet spectrum of anthracene.

The thinnest of these crystals show retardations under the polarizing microscope of less than 100 $\mu\mu$ and are pale gold, or occasionally blue, by reflected light. Their thickness is of the order of $0{\cdot}1\,\mu$. Specimens examined by X-rays invariably show that the developed face is a (001) plane, and this contains the $a$- and $b$-crystal axes which are mutually perpendicular. The positions of the $b$-axis were found either by means of X-rays or microscopy, and the crystal mounted on a rotating stage with its face perpendicular to the optic axis of a Hilger Littrow quartz spectrograph. Light passed through the crystal into a quartz Wollaston prism and on to the slit, the two beams of plane-polarized light being about 4 mm. apart. The optical densities for the two directions of polarization were measured by sector photometry against equally long exposures of the light source without the crystal. The ratio of these optical densities for electric vector directions parallel to the $a$- and $b$ crystal axes was compared with that calculated from the known inclinations of molecular axes within the crystal.

The spectral range accessible to the quartz spectrograph includes three regions of absorption, each corresponding to a distinct band system of anthracene. In the systems at 3800 A. and 2700 A., absorption is greater for the electric vector parallel to the $b$-crystal axis; in the system at 2300 A. absorption is less for the $b$- and greater for the $a$-direction. These results cannot at once be put in terms of molecular axes, since three molecular axial directions cannot be characterized from two crystal directions. However, much evidence suggests the inactivity in transitions in the near ultra-violet of one of the molecular axes, namely, that normal to the plane of the rings; and if this inactivity be accepted, it follows from our results that the band system at 2700 A. is polarized along the shorter in-plane axis, that the system at 3800 A. has at least a strong component along this axis, and that the system at 2300 A. is polarized along the longer in-plane axis.

There is clear evidence in the 3800 A. band system of the displacement of the absorption maxima in $a$-polarization from those in $b$-polarization, so that the whole band system appears to be displaced as well as changed in intensity, as the polarization direction of the incident light changes in the $ab$ face. The split maxima have separations in the range 50–100 cm.$^{-1}$. This may be the phenomenon, a theory of which was first given by Davydov[3], in which intermolecular forces split the molecular energy-levels into pairs of crystal states with different polarization properties.

These preliminary results will later be incorporated in a more complete report. We wish to acknowledge valuable discussions with Prof. C. K. Ingold. We have also received important help from Dr. H. G. Poole, who designed the optical arrangements, and from Mr. Philip Knight, who made several X-ray examinations of anthracene crystals and so made possible their correct orientation in the light beam.

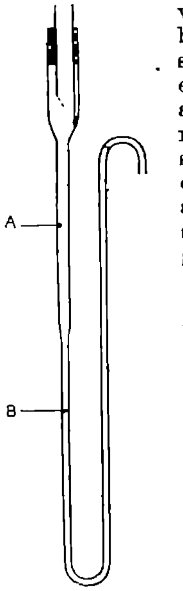
## Estimation of the 9 : 10-Dihydroxystearic Acids and their Acyl Derivatives

The occurrence of esters of 9 : 10-dihydroxystearic acid (melting point, 132°) among the autoxidation products of oleic and elaidic acids has been established by Ellis[1], who utilized the sparing solubility of the dihydroxy acid for its isolation and estimation. In the presence of a high proportion of oily products, however, a quantitative separation of the acid is sometimes difficult, and the presence of silica following prolonged alkaline hydrolysis may also be a source of error.

The method of estimation to be described takes advantage of the fact that, under suitable conditions, periodic acid oxidizes the 9 : 10-dihydroxystearic acids almost quantitatively to nonaldehyde and azelaic semialdehyde[2], of which the former may readily be isolated by distillation in steam and its



volume measured. The reaction is best carried out in feebly alkaline solution, avoiding an unnecessary excess of periodate. Thus, an amount of material containing not more than 1 gm. of dihydroxystearic acid is dissolved in 100 ml. of seminormal sodium hydroxide and brought to $p$H 8 with dilute sulphuric acid. After adding 0·2 gm. (0·75 gm. if the amount of dihydroxy-acid is thought to exceed 0·25 gm.) of potassium periodate, the solution is distilled at a moderate rate through a simple water-cooled condenser into a trap (see diagram), in which the non-aldehyde collects as a nearly insoluble oil on the surface of water in the tube *A* (bore 3·5 mm.; length 7·5 cm.), while the aqueous part of the distillate siphons over into a measuring cylinder[1,2]. When no further aldehyde distils over and some 20 ml. of water has been collected, the trap is detached and the oil run into the capillary *B* (bore c. 1·75 mm.), where its depth is accurately measured after standing for 10 min. or more. The capillary may be calibrated by oxidizing pure dihydroxystearic acid (melting point, 132°) under the same conditions; or, if the bore of the capillary is known, the mass of non-aldehyde (*d*, 0·827) can be calculated, an allowance of 0·001 gm. being made for its solubility in 20 ml. of aqueous distillate. The yields of nonaldehyde (Table 1) range from 82 to 95 per cent of the theoretical and, except for very small amounts, are reproducible to within ± 2·5 per cent; but it is important that the still and trap should be cleaned with chromic-sulphuric acid and well washed prior to each estimation. The isomeric dihydroxy-acid (melting point 95°) gives almost identical results.

Table 1

(*a*) Using 0·20 gm. of potassium periodate

| | | | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|
| Dihydroxystearic acid (mgm.) | 25 | 50 | 75 | 100 | 125 | 150 | 175 | 200 | 225 | 250 |
| Nonaldehyde (mgm.) | 10 | 18·5 | 28·5 | 39 | 49 | 59 | 70·5 | 84·5 | 96·5 | 108 |

(*b*) Using 0·75 gm. of periodate

| | | | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|
| Dihydroxystearic acid (mgm.) | 100 | 200 | 300 | 400 | 500 | 600 | 700 | 800 | 900 | 1,000 |
| Nonaldehyde (mgm.) | 37·5 | 80 | 120 | 163 | 207 | 252 | 295 | 340 | 385 | 422 |

For the estimation of acyl esters of dihydroxystearic acid, 0·75–1·0 gm. of the material is saponified by refluxing or, where volatile hydrolysis products are formed[1,4], slowly distilling with 100 ml. of seminormal aqueous sodium hydroxide for 2 hr. The cooled solution is diluted if necessary to about 100 ml., brought to $p$H 8 and distilled with periodate as described. When estimating esters in autoxidized oleic or elaidic acid, certain corrections may be necessary. First, elaidic acid oxide, which is normally present[4], is saponified to dihydroxystearate under these conditions to a variable extent. The amounts of nonaldehyde arising from this source are given in Table 2. Secondly, 10-hydroxy-9-ketostearic acid similarly gives a good yield of nonaldehyde on oxidation with periodate[5]; but except during the advanced stages of autoxidation neither this nor free dihydroxystearic acid appears to occur in significant amount in these products, as may be shown by distilling the unsaponified material at $p$H 8 without and with periodate.

Table 2

| | | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|
| Elaidic acid oxide (mgm.) | 25 | 50 | 100 | 150 | 200 | 250 | 300 | 400 | 500 |
| Nonaldehyde (mgm.) | 8 | 9·4 | 11 | 12·1 | 13 | 14 | 14·7 | 16·1 | 17·3 |

A few typical results are summarized in Table 3.

Table 3

| | Dihydroxystearic acid (per cent) | | |
|---|---|---|---|
| | Present, or theoretical value | Found | |
| | | Periodate method | Isolation method |
| Mixture of dihydroxystearic acid (m.p. 132°), and elaidic acid | 20·0 | 19·9 | 19·7 |
| Mixture of dihydroxystearic and oleic acids | 20·0 | 19·4 | 16·2 |
| Mixture of dihydroxystearic and nonanoic acids | 66·7 | 67·8 | — |
| Autoxidized elaidic acid (corrected value) | — | 7·0 | 5·5 |
| Oily fraction of the above, insoluble in *n*-hexane | — | 12·4 | 6·7 |
| Impure mono-azelaate of dihydroxystearic acid, after saponification | 65·0 | 62·2 | 62·4 |
| 9 : 10-Hydroxyacetoxystearic acid (m.p. 81°) after saponification | 88·3 | 85·5 | — |

The scope of the periodate reaction is well known[6] and the method should be applicable to other suitable 1 : 2-glycols or ketols.

## Hardening of Kaolin on Rehydration

An investigation of the durability of fired clay minerals revealed an unexpected hardening of kaolin on rehydration. Samples from Gordon, Victoria, fired at 500°–950° C., followed by rehydration in saturated steam at 200° C. for periods up to 96 hr., showed compressive strengths for small cylinders of 5,000–14,000 lb./sq. in., compared with strengths of 1,000–2,000 lb./sq. in. before rehydration. The compressive strength of the kaolin fired at 1,250° C. was 4,000 lb./sq. in.

X-ray analysis of the rehydrated kaolin indicates that the increase in strength may be related to a higher crystal symmetry, since the powder pattern has fewer lines, with *k* reflexions absent or reduced in intensity. Electron micrographs of the original material before and after firing show well-formed hexagonal flakes, whereas the rehydrated kaolin is composed of clusters of much smaller and more irregular particles similar in appearance to those of the 'third form' of kaolin discussed by Bramao *et al.*[1]. This kaolin, however, differs from the rehydrated material in having a disordered structure.

Differential thermal curves show a large endothermic peak at 130°–150° C., followed by a continuous endothermic reaction up to the main endothermic peak at 550° C., some 70° C. lower than the corresponding peak in the original kaolin. The final exothermic peak is unaffected. Activation energy for the main dehydration process calculated from the differential thermal curves is about 40 kcal. for the rehydrated kaolin, compared with 55 kcal. for the original material. The slope ratio of the main endothermic peak is 4–1 for the rehydrated material, a figure which has been thought characteristic of halloysite[1]. The slope ratio for the untreated kaolin is 1·25–1.

Preliminary tests on other materials indicate that the hardening effect occurs in relatively well-crystallized kaolins.

Possible industrial applications of the phenomenon are being investigated.

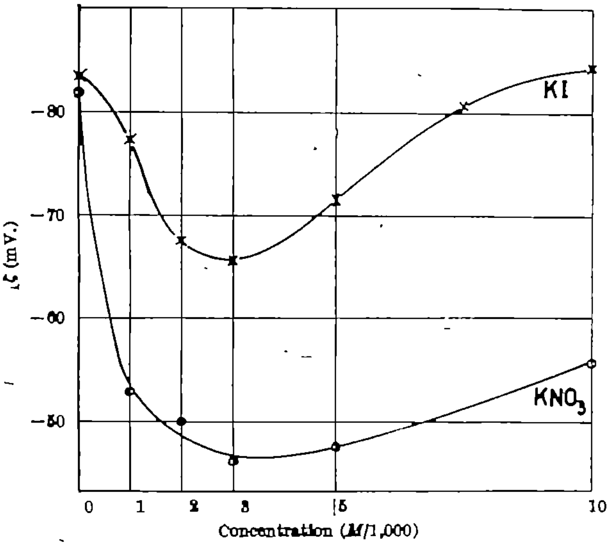
## Centrifugation Potentials in Sols of Silver Iodide

If a sol is centrifuged, an electrostatic potential difference is set up between two points in the sol at different distances from the axis of rotation (centrifugation potential)[1]. These potentials are connected with the $\zeta$-potential of the colloidal particles by the formula:

$$V_{\mathrm{C.P.}} = \frac{m'n}{\sigma}\,\frac{D\zeta}{6\pi\eta}\,\frac{\omega^2}{2}\,(R_2^2 - R_1^2). \qquad (1)$$

Here $m'n$ is the apparent mass of dispersed substance per cm.$^3$, $\sigma$ the electrical conductivity, $\eta$ the viscosity, $D$ the dielectric constant of the sol, $\omega$ the angular speed of rotation, and $R_2$, $R_1$, the distances from the axis of the two points between which the centrifugation potential is measured. Conversely, from the value of $V_{\mathrm{C.P.}}$, $\zeta$ can be calculated; therefore the measurement of centrifugation potentials is of considerable interest.



Values of $\zeta$ in sols of silver iodide after the addition of potassium nitrate and of potassium iodide

Extensive measurements of these potentials in sols of arsenic trisulphide have been made by G. Jacobs[2]. One of his results, and certainly the most unexpected, was the shape of the $\zeta - c$ curves for the addition of indifferent electrolyte (potassium nitrate). Between 0 and 3 millimol./l., $\zeta$ decreases from − 100 to − 73 mV. and then rises slowly again.

We decided to repeat these measurements, in order to see whether Jacobs's result was a general one, for sols of silver iodide. To obtain the necessary quantities a continuous electrodialyser was constructed[3]. We prepared a concentrated sol, containing 50 gm./l. of silver iodide; the coarsest particles were eliminated by pre-centrifugation, resulting in a sol of about 20 gm./l. with which the measurements were made.

The results are shown in the accompanying graph; the reproducibility of the points was about 3 per cent. There is again a strong decrease of $\zeta$, followed by a slow increase, for the addition of indifferent electrolyte; for the addition of potential-determining electrolyte, there is also a decrease of $\zeta$, followed by a much more marked increase. This last feature is in agreement with expectation, and gives us confidence in the experimental procedure; the first result is quite unexpected, and, so far as we are aware, cannot be explained by the current theories of the double layer. In fact, these theories always lead to a monotonic change of $\zeta$ with concentration.

We are proposing to make simultaneous measurements of $\zeta$ and $\varepsilon$ (the total potential) in order to obtain more insight into this problem.

## Curves of Succinoxidase Inhibition by Surface-active Agents

Inhibition of the succinoxidase system by a variety of surface-active agents has been noted by Hockenhull[1]. The inhibition of this enzyme system by certain water-soluble androgens has recently been demonstrated[2]. The effect of these androgens suggested a surface phenomenon[3].

Two detergents were therefore studied in this laboratory to compare curves of inhibition with those found for the androgens. Sodium deoxycholate was chosen because it is both an ionic detergent and a soluble steroid salt. Polyoxyethylene sorbitan monolaurate ('Tween 20') was the neutral detergent used. The manometric technique employed was that described in Umbreit's text-book[4]. The accompanying curves (Figs. 1 and 2) show the influence of detergent concentration on the succinoxidase system of rat liver.

The sigmoid shape of these curves is similar to that of curves obtained when sodium androsterone sulphate is the inhibiting agent. If we consider per cent inhibition analogous to uptake of inhibitor by the enzyme system, we may compare the curves obtained here with adsorption curves in other system For example, Coolidge[5] found this type of curve the adsorption of water vapour by charcoal ur conditions of increasing vapour pressure. Evid derived from the work with androgens indicate

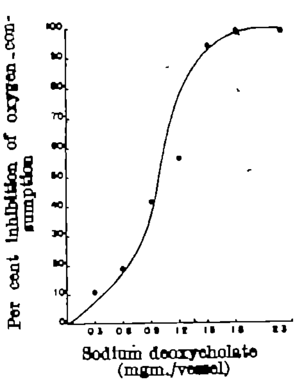

Fig. 1

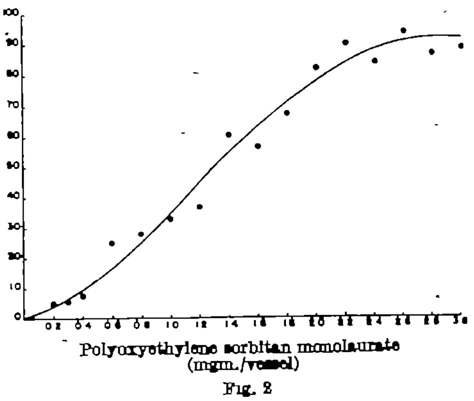

Fig. 2

Fig. 1. Effect of concentration of sodium deoxycholate on the succinic dehydrogenase system

Fig. 2. Effect of concentration of polyoxyethylene sorbitan monolaurate ('Tween 20') on the succinic dehydrogenase system

succinic dehydrogenase is the target of the inhibitor[5]. It is suggested that the mechanism of inhibition of the isolated succinoxidase system by surface-active agents is due to their adsorption by succinic dehydrogenase.

I am indebted to Prof. W. C. Cutting for helpful suggestions.

## The Trinitratouranyl Complex Ion

SALTS having the general formula $M[UO_2.(NO_3)_3]$ (where $M$ is $NH_4$, K, Rb, Cs) have been referred to in recent literature[1]. The tetramethylammonium salt has been prepared by reaction of the appropriate nitrates in pure nitric acid medium[2], and the identity of a trinitratouranyl ion has been established in solutions of uranyl and tetra-*n*-butylammonium nitrates in acetone or methyl isobutyl ketone[3].

Comparison of the ease of formation of the trinitrato- with that of the tetranitrato-complex is of importance in the chemistry of uranyl compounds, particularly in view of the unusual co-ordination number apparently involved in the former compound. It is therefore interesting that salts of the trinitrato-complex are formed directly from uranium metal by reaction in liquid dinitrogen tetroxide, under experimental conditions which do not favour the formation of any one particular complex. Reaction between the pure metal and liquid dinitrogen tetroxide is very slow; but when diethylammonium nitrate is dissolved in the tetroxide, reaction becomes rapid, with evolution of nitric oxide. On standing, the liquid deposits transparent yellow-green crystals which contain no combined dinitrogen tetroxide; analysis of this product is in accord with the formula $(Et_2NH_2)[UO_2.(NO_3)_3]$. When a dilute solution of this compound is electrolysed, the ion containing uranium migrates to the anode, confirming that the uranyl group is present in an anionic complex. Using diethylammonium nitrate solutions, this is the only salt which crystallizes. A similar reaction occurs with solutions of mono- or tri-ethylammonium nitrate in liquid dinitrogen tetroxide; with the monoethyl compound the crystalline product varies in composition with concentration of the solution, and is probably a mixture of the salt $M[UO_2.(NO_3)_3]$ with a little of the tetranitratouranyl salt $M_2[UO_2.(NO_3)_4]$. However, the ready formation of the trinitratouranyl complex under these conditions illustrates its high stability in media of low dielectric constant. The complex undergoes ionic dissociation in water.

The rates of the above reactions show large positive temperature coefficients. Again, the rate of reaction between uranium metal and the liquid tetroxide alone is increased by the addition to the tetroxide of other compounds (for example, diethylnitrosamine) able to increase the dielectric constant of the medium. For these reasons (as with metallic zinc[4]) we consider that the initial (rate-determining) reaction involves $[NO^+]$ $[NO_3^-]$ ion-pairs, so that:

$$U + n\mathrm{NO}^+ = U^{n+} + n\mathrm{NO}$$

On kinetic grounds, $n$ is likely to be a small number. Reaction of the ion with the tetroxide then gives rise to progressive oxidation:

$$U^{n+} \xrightarrow{N_2O_4} UO^{2+} \xrightarrow{N_2O_4} UO_2^{2+}$$

Only the hexavalent uranium salt crystallizes, although the mother liquor contains some uranium in a lower valency state.

Many reactions in liquid dinitrogen tetroxide may be correlated on the basis of a solvent system[5] which involves the ionization:

$$N_2O_4 \rightleftharpoons NO^+ + NO_3^-$$

The salts described above illustrate clearly the amphoteric nature of uranium in this solvent system. The $NO_3^-$ ion is equivalent to the $OH^-$ ion in the aqueous system, and there is a striking similarity between the commonest type of uranate produced in 'basic' solutions of the two media.

| | $H_2O$ system | | $N_2O_4$ system |
|---|---|---|---|
| (*A*) | $M_2U_2O_7.3H_2O$ | | |
| (*B*) | $M_2[(UO_2)_2.(OH)_6]$ | (*D*) | $M_2[(UO_2)_2.(NO_3)_6]$ |
| (*C*) | $M[UO_2.(OH)_3]$ | (*E*) | $M[UO_2.(NO_3)_3]$ |

Treatment of a uranyl compound in aqueous solution with alkali results in the precipitation of the diuranate (*A*). If three molecules of water are regarded as constitutional, the compound may be formulated as (*B*) or (*C*). The analogous compound produced from liquid dinitrogen tetroxide is (*E*), or its dimeric form (*D*). Structures (*B*) and (*D*) are attractive, in that they enable the compounds to be formulated as binuclear complexes of 6-co-ordinate uranium, although crystal structure determinations on the compound $Rb[UO_2.(NO_3)_3]$ indicate that in this salt the uranyl complex is mononuclear[6].

We wish to thank the Director, Atomic Energy Research Establishment, Harwell, for making available a supply of pure uranium metal.

## Reversible Dissociation of Insulin

In the past few years the dissociation of insulin in acid and neutral solution has been extensively studied. Although most of this work has pointed towards a minimum molecular weight of 12,000 from osmotic pressures[1], sedimentation[2,3] and light scattering[4] measurements, we raised the possibility of a value of 6,000 as the lower limit, from the extrapolation of sedimentation and diffusion data[5]. This value has been confirmed by surface monolayer studies[6] and by Craig and Harfenist's method[7]. Further, chemical analysis does not preclude it[8].

It has already been postulated that insulin molecules dissociate when the electric charge is increased by fixation of protons, this producing a repulsion between positively charged submolecules. It would be expected that a similar phenomenon would occur in alkaline media when submolecules carry a sufficiently high negative charge.

In the present investigation we have determined sedimentation and diffusion constants in moderately alkaline solutions of insulin, respectively by a 'Spinco' analytical ultracentrifuge and by the Lamm's scale method. (The insulin used was five times recrystallized beef insulin obtained through the courtesy of the Lilly Research Laboratories, Indianapolis.)

Fig. 1 shows the effect of $p$H on the sedimentation constant of insulin (corrected to 20° and water) at a constant concentration of 0·25 per cent protein and ionic strength 0·1. The dissociation becomes effective around $p$H 8 and reaches its maximum by $p$H 10. Titration curves indicate that at this $p$H insulin carries about 10 negative charges (calculated on the basis of 12,000 molecular weight). This is identical with the positive charge of insulin at $p$H 3 where maximum-dissociation takes place also[5]. This behaviour provides good evidence that the dissociation is mainly determined by electrostatic repulsions.

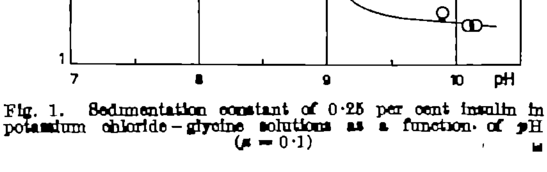

Fig. 1. Sedimentation constant of 0·25 per cent insulin in potassium chloride – glycine solutions as a function of $p$H ($\mu$ = 0·1)

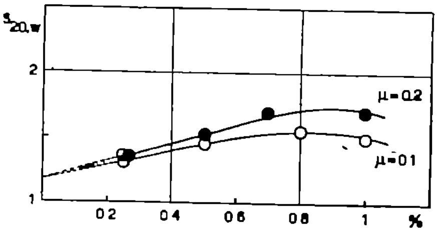

Fig. 2. Sedimentation constant of insulin in potassium chloride-glycine solutions at $p$H 10·1 as a function of protein concentration

Fig. 2 shows the effect of protein concentration on the sedimentation constant of insulin at $p$H 10·1 and ionic strength 0·1 and 0·2 (buffer potassium chloride – glycine). As at[5] $p$H 2·7, the sedimentation constant rises when the concentration decreases from 1 to 0·7 per cent, in accordance with the ordinary charge effect, but goes down below this point because the dissociation becomes the overwhelming factor. At both buffer concentrations the values tend to become identical and point towards a minimum around 1·2. Similar conclusions can be drawn from diffusion data (Table 1).

Table 1. Diffusion Constants of Insulin at $p$H 10·1 (Corrected to 20° and Water)

| | Potassium chloride – glycine 0·1 $N$ | Potassium chloride – glycine 0·2 $N$ |
|---|---|---|
| 0·15 per cent | 15·7 | 14·1 |
| 0·30 ,, | 15·0 | 12·5 |
| 0·45 ,, | — | 11·3 |

The extrapolation of sedimentation and diffusion constants at zero protein concentration gives an approximate value for the insulin submolecule. It is much lower than 12,000. A combination of $s$ = 1·2, $D$ = 16 and a partial specific volume of 0·72 [8] would give a molecular weight around 6,000.

The stability of insulin in these moderately alkaline solutions under the experimental conditions given is well established by Waugh's experiments on the biological activity of insulin after alkali treatment[9]. On the other hand, it can be completely and easily recrystallized after standing two days at $p$H 10 at room temperature. It also regains its normal sedimentation constant when brought back to $p$H 7.

Although in acid solution the sedimentation constant varies with the sample of insulin considered and with its age, results are much more constant at $p$H 10 (Table 2).

Table 2. Sedimentation Constants of 0·25 per cent Insulin at Ionic Strength 0·1

| | $p$H 2·7 | $p$H 10·1 |
|---|---|---|
| Lot *T*-2344 | 1·3 to 1·6 | 1·3 |
| Lot 483.098 | 1·8 | 1·3 |
| Lot 200-1*B*-11 | 1·5 | 1·3 |

Similarly, in neutral or alkaline media, the dissociation is not influenced by the nature of the anions present; 0·1 $N$ phosphates, chlorides or thiocyanates give identical values for $s_{20}$ at $p$H 10·1. In acid solutions the dissociation is much influenced by the nature of the anions[5]. We related it to the binding capacity of insulin for such ions; this binding capacity does not exist in alkaline solutions.

It has been pointed out[5] that the lowering of the dielectric constant of the medium will increase the tendency of insulin to dissociate. Experiments in solutions of 20 per cent dioxane in water and 0·2 $N$ potassium chloride show that the sedimentation constant of insulin both at $p$H 3·6 and 8 is markedly depressed. At $p$H 3·6 a molecular weight of 13,700 has been deduced from sedimentation-diffusion in 20 per cent dioxane – 0·2 $N$ potassium chloride; in aqueous solution it is more than 30,000. Moreover, the use of still higher concentrations of dioxane greatly increases the solubility of insulin in the isoelectric region. In 40 per cent dioxane – 0·5 $N$ potassium chloride, 1 per cent insulin can be kept in solution throughout the entire $p$H scale.

A detailed account of this work will be published elsewhere. We gratefully acknowledge a research grant from Eli Lilly and Co., Indianapolis.

## Apparent Degradation of Wool by Diazomethane Solutions

THE action of diazomethane on proteins has been studied by a number of workers, who report that both O- and N-methylation occur. There is apparently no fission of the peptide chains, although it is stated[1] that the action of diazomethane on insulin causes a decrease in the cystine content. On the other hand, Kirst[2] claims that the cystine bridges in wool are unaffected by the reagent, and Herzig and Landsteiner[3] state that wool is rather more resistant to diazomethane than are other proteins. In most of this earlier work, it was specifically stated that dry proteins and dry ethereal solutions of diazomethane were used. Recently, Kuhn and Ruelius[4] have shown that diazomethane acts on aqueous solutions of peptides with formation of the corresponding betaines, while serum albumin and ovalbumin in water are slowly converted to insoluble products. We have now found that wool can be extensively degraded by ethereal diazomethane solutions, the product being almost completely soluble in water. The diazomethane, prepared from nitrosomethylurea, is added to the wool over a period of several days, together with small quantities of water. The soluble product contains no sulphur, and diffuses through 'Cellophane', while the appearance of the wool during the reaction closely resembles that of wool treated with strong alkali.

Diazomethane is known to contain methylamine as an impurity[5], and our solutions were approximately 0·01 $N$ with respect to this compound. However, this weak base alone is without visible attack on wool even at high concentration. Although there is apparently very little action between diazomethane and aliphatic amines in water-free solution (cf. ref. 6), we have found that, when water is present, methylamine, but not higher aliphatic amines, is slowly methylated, producing first trimethylamine and then tetramethylammonium hydroxide, as proved by potentiometric titration and isolation of the corresponding crystalline iodides. The quaternary ammonium hydroxide is a very strong base, and the amount produced from the methylamine impurity in the diazomethane solutions, when absorbed from the ether solution by the small amount of water on the wool, is more than enough to account for the extensive digestion observed. In fact, wool is attacked even by solutions in which the diazomethane has been previously destroyed by the addition of small amounts of water. Samples of diazomethane prepared from $p$-toluenesulphonmethylamide[7] or from hydrazine and chloroform[8] also contain basic compounds and show a similar degradation of wool. The removal of the methylamine impurity proved difficult, but partial success was achieved by repeated treatment with either methyl iodide or $p$-toluenesulphonyl chloride followed by distillation. These base-free solutions show no degradative attack on wet wool.

The above results indicate that some caution might be necessary when diazomethane is used in protein studies, for example, in Chibnall's method for the determination of C-terminal residues[9]. Further, it would appear likely that some of the results observed by Head[10] during a study of the action of diazomethane on cotton and various modified cotton celluloses could be attributed to the presence in the reagent of tetramethylammonium hydroxide.

## Nitrogen Metabolism of Apple Trees

IN most plants nitrate is the form in which nitrogen is absorbed from the soil and translocated upwards from the roots. Accumulation of nitrate in upper parts of the plant may follow, nitrate reduction and formation of organic nitrogen compounds occurring in many organs. Thomas[1] showed that the nitrogen uptake of apple trees was atypical in that nitrates could normally be detected in only the finest roots, and suggested that nitrate reduction and formation of amino-acids occurred in these organs. Absence of nitrates from apple leaves has since been confirmed by many workers; but under certain conditions they have been detected[2].

During work on stock-scion nutrient interrelations in the apple, the nitrogen supply from stock to scion has been investigated. This was done by examining the level and forms of nitrogen present in tracheal sap, extracted by a simplification of the method of Bennett *et al.*[3], from one-year old shoots of mature apple trees.

The total nitrogen content of this sap, as determined by a micro-Kjeldahl method, showed considerable seasonal variation. Over the winter months the sap contained approximately 10 μgm. of nitrogen per ml. There was an increase to 20 μgm. about three weeks before blossoming, followed by a rise to a peak of 150 μgm. at flowering (about October 1). This level was maintained for about three weeks, and

FRACTIONATION OF TOTAL NITROGEN OF TRACHEAL SAP OF APPLE TREES

| 24/ 3/52 | Granny Smith | Malling XII | 0 | 1 | 2 | 13 | 16 | 19 |

from time of petal fall there was a gradual decline until, at the end of January, the level was down to 20 μgm. and by the end of March it was back to 10 μgm.

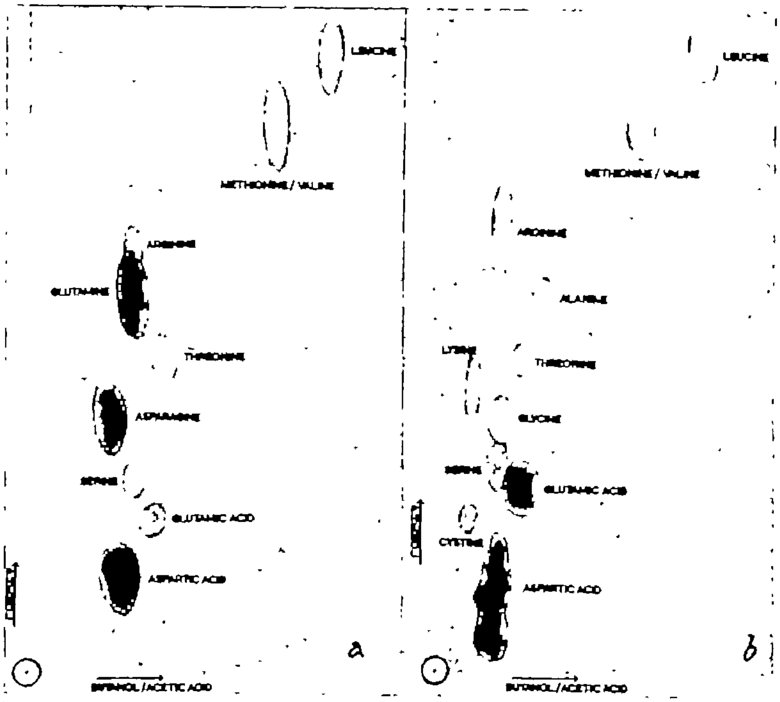
Fractionation of this nitrogen has been possible. Using phenol disulphonic acid, no nitrate could be detected. Ammonia, glutamine amide and asparagine amide were determined by vacuum distillation methods[4]. Amino-nitrogen was determined in the Van Slyke manometric apparatus, the usual correction for glutamine amide nitrogen being made. Results obtained from sap extracted at different times during the season are given in the accompanying table. It is apparent that ammonia + amide + amino-nitrogen can account for all the nitrogen present.

The individual nitrogenous compounds have been examined by paper chromatography. Tracheal sap, concentrated *in vacuo* at room temperatures, was run in phenol and butanol/acetic acid. Amino compounds were revealed by spraying with ninhydrin (0·1 per cent in *iso*propanol). The principal compounds present were always glutamine, asparagine, aspartic acid and, to a lesser extent, glutamic acid. Judged by spot intensity, these four compounds would account for up to 90 per cent of all nitrogen present. Also present in lesser amounts were serine, threonine, arginine, methionine, valine and leucine. Sometimes present in traces were alanine, tyrosine and γ-amino butyric acid. On acid hydrolysis of sap, the serine and alanine spots increased in intensity, while glycine and faint spots corresponding to lysine, cystine and sometimes cysteic acid appeared, indicating the probable presence of a peptide.

Recent work[5] has confirmed, at least with some plants, the older view that solutes absorbed by the roots pass up through the xylem vessels. The present work has shown that in the apple tree this sap contains nitrogen throughout the year, and, at times, is comparatively rich in this element. It would seem that a significant part, if not all, of the nitrogen absorbed by the root system does pass to the scion in the xylem sap.

The view that complete reduction of nitrate to amino-acids occurs in the roots is substantiated. Apart from a small amount of ammonia nitrogen, the nitrogen of amino-acids and amides accounts for all the nitrogen in the tracheal sap.

The predominance of the two dibasic amino-acids might be expected as they, together with their amides, are considered to be some of the first products formed in the synthesis of organic nitrogenous compounds. Their importance as translocatory compounds has been shown here. The presence of glutamine is of particular interest as it has not been detected[6] free in apple fruits.



Paper chromatograms showing amino-acids of tracheal sap of Granny Smith apple tree on Northern Spy stock: (*a*) sap concentrated *in vacuo* at room temperatures; (*b*) sap hydrolysed in 6*N* hydrochloric acid for 3 hr.

It is hoped to publish these results in more detail elsewhere.

## Effect of Leaf Roll Virus Infection on the Soluble Nitrogen Composition of Potato Tubers

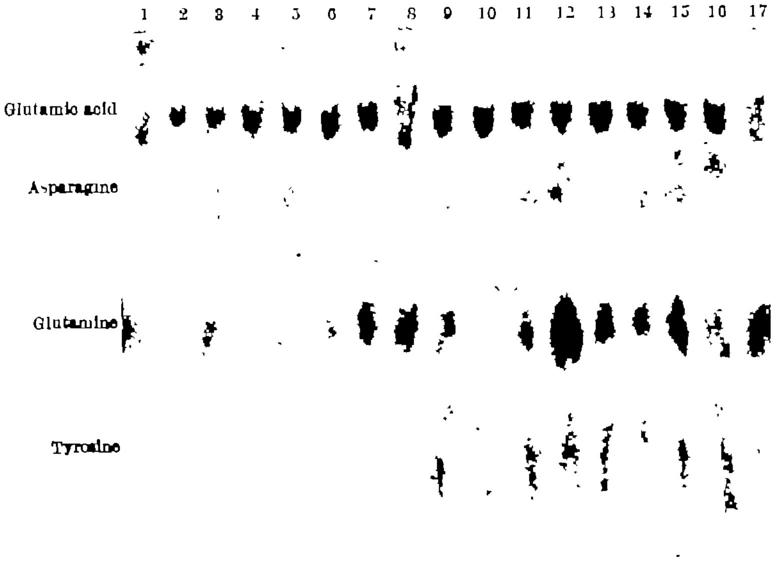
In an attempt to verify and extend the findings of Andreae and Thompson[1] to a range of potato varieties, an apparent relationship between glutamic acid, glutamine, and virus infection has been noted. The diseased tissue used was primary infected material which had been obtained from grafts.

Microscopic examination of the tissue did not reveal the presence of necrotic lesions, which, because of the gross physiological changes involved in their formation, might conceivably be expected to produce, as secondary effects, similar biochemical differences to those found. Alcoholic extracts were prepared according to Dent, Stepka and Steward[2], taking the same weight of healthy and diseased tuber tissue (20 gm.) for each extraction. A preliminary survey of seven varieties was made by applying equal volumes of the extracts to a one-dimensional paper chromatogram (see photograph) run in phenol : water, 75 : 25 w/v. A standard set of amino-acids containing aspartic and glutamic acids, glutamine and tyrosine was run in the first, eighth and seventeenth positions. One of these compounds, glutamine, contained impurities which confuse the picture in the aspartic – glutamic acid region. In four of the seven varieties the diseased tissue appears to contain higher concentrations of glutamic acid, glutamine and asparagine. Two-dimensional chromatograms, run with *n*-butanol : acetic acid as the second solvent, showed that the amounts of alanine present were insufficient to account for the large differences appearing in the glutamine region of the single-dimensional chromatogram, but that other amino-acids, for example, serine, accounted for the apparent differences in asparagine content.

Analyses of five further varieties by two-dimensional chromatography have shown that the differences in glutamic acid and glutamine are the most consistent. Diseased tissue had two to three times the glutamine concentration of healthy tissue, while glutamic acid differences were much smaller although covering the same varietal range. Tyrosine and tryptophane, however, showed no consistent differences over the varietal range tested. A very noteworthy biochemical difference occurs in Arran Pilot tubers, in which the total amino-nitrogen in diseased tissue appears to be reduced to approximately one-third of that present in healthy tissue.

In view of the importance recently assigned to glutamic acid and the γ-glutamyl group of glutamine by Hanes, Hird and Isherwood[3], in respect of transpeptidation reactions, these observations may have significance beyond the fact that they show promise of providing the basis for a simple and rapid diagnostic test for leaf-roll virus in potato tubers.

A fuller account of this work will be published elsewhere. I acknowledge gratefully the co-operation of Mr. C. M. Driver, who provided the material, and Miss C. M. Smart, who performed the grafts and microscopic examination of the material.



Chromatogram of soluble nitrogen fraction of healthy and diseased potato tubers. (1), (8) and (17) are standard amino-acids. The following pairs are for each variety, healthy and diseased, respectively (2, 3) Arran Banner; (4, 5) Arran Chief; (6, 7) Arran Consul; (9, 10) Arran Pilot; (11, 12) Chippewa (13, 14) Craig's Defiance, (15, 16) Dunbar Standard

## Bacterial Degradation of Choline

During work on the production of trimethylamine by organisms isolated from the flora of the whale, it was found that some types were able to produce this substance from choline[1]. Similar observations on organisms from other sources had been made previously, the products of the degradation of choline characterized as trimethylamine and ethylene glycol, and the enzyme responsible named 'choline deaminase'[2]. No kinetic information was available, nor had the specificity of the enzyme been determined, though it had been reported that certain Enterobacteriaceæ produce trimethylamine from acetylcholine but not from betaine[3], so investigation of these questions seemed likely to prove fruitful.

The organism used was a strain of *Aerobacter aerogenes*, recently isolated from whale tissue, chosen in preference to the other choline-splitting species, which were either anaerobes or slowly growing aerobes. Its enzyme system proves to be specific for choline and acetylcholine. Ethyltrimethylammonium hydroxide and tetramethylammonium hydroxide may be attacked very slightly; but with the small quantities involved it is difficult to tell whether the trimethylamine has increased or not. It is without action on *iso*-choline, betaine, phosphorylcholine or dimethylaminoethanol.

It has been reported that trimethylamine production from choline is inhibited by glucose, and suggested that this is because the ethylene glycol simultaneously produced is no longer needed as a source of energy[3]. We have confirmed the inhibition by glucose but have found that ethylene glycol does not prevent choline breakdown. Kinetic experiments have proved to be impossibly difficult, but some observations have been made which seem worth recording. Choline is attacked by *A. aerogenes* only in the logarithmic phase of growth. When active division ceases, so also does production of trimethylamine; washed suspensions are completely inactive. The enzyme system involved is not adaptive.

We have been unable to proceed further because of difficulties in the chemical estimation. Choline cannot be estimated by the reineckate method in the presence of trimethylamine which is also precipitated, and ethylene glycol is probably metabolized. Trimethylamine can be estimated by titration with perchloric acid in a non-aqueous system or by a colour reaction with *cis*-aconitic anhydride. Both methods require the extraction of the base into an organic solvent, and we have found that direct extraction with toluene is incomplete at the higher concentrations (60–70 mgm. per cent), and that in the lower ranges (0–20 mgm. per cent) it is impossible to aspirate the trimethylamine completely into glacial acetic acid. A method of trimethylamine estimation by gas–liquid partition chromatography has been devised, but it is unsuitable for serial estimations in kinetic experiments[4].

This work was carried out as part of the programme of the Food Investigation Board of the Department of Scientific and Industrial Research.

## 'Parsnip Canker'

Green and Hewlett[1], in a summary of their investigations on 'parsnip canker', stressed the importance of the disease and showed that the term 'canker' had been loosely applied to several infections which they therefore specified and classified. They concluded that only the commonest form, and the one without a known causative agent, should be so named, and they suggested that critical indoor rather than field experiments would be needed to reveal the agent. We have found from such experiments carried out over several seasons that cultures of *Streptomyces scabies* (Thaxter) Waksman and Henrici cause cankering and other stages of parsnip scabbing.

The possible link between 'canker' and the scab pathogen was indicated by cankering of parsnips and scabbing of carrots growing adjacently in a field, and led to a test of the infectivity of a culture of *S. scabies* to parsnips. The resultant cankering suggested tests of further cultures of the pathogen, which confirmed the first infection and showed that one culture, Millard and Burr's[2] strain 17, formed a common range of lesions on potatoes, beet, mangolds and radishes as well as on carrots and parsnips. Frequently one kind of lesion predominated, so that the raised scab characterized the infections on beet, mangolds, French breakfast radishes and carrots, while the surface-to-sunken sort prevailed on the potato, white icicle radish and on mature parsnips; but on parsnip seedlings the scabs were raised at first. Throughout these infections, except where union had blotted out their origins, it was clear that lesions arose in lenticels and, in all plants except the potato, the centring of lenticels in side-root rows permitted the involvement of root initials. Microtome sections confirmed this possibility, especially in carrot scabs, and they also showed, in both carrot and parsnip lesions, the series of cell changes noted by Jones[3] in potato scabs. The similarity in structure of the pitted scab of the tuber and that of parsnip cankers was close even in details, but the cankers usually formed only one protective cork barrier.

The presence of the pathogens in lesions was confirmed by re-isolating them several times and in different seasons and, in one season, a number of isolates so obtained from carrot and parsnip lesions cankered parsnips in a later season. In addition, the cultural and morphological features of the isolates agreed with those of the infecting cultures. Since the cultures used were of varied and widespread origin, being derived from potato or beet scabs formed in England, Wales and the United States, and the culture most commonly used, Millard's strain, is a well-known potato pathogen capable of scabbing several kinds of crop, these pathogens could, no doubt, cause in Nature the commonest sort of 'parsnip canker' noted by Green and Hewlett.

## The Term 'Soil'

When a term of wide use is shared between different scientific disciplines, some confusion may result from its use in publications of common interest unless there is complete agreement regarding its meaning. Such a term is the word 'soil', the rapid development of the scientific study of unconsolidated mineral aggregates by engineers having given rise to much pointed criticism of their use of this very common word.

To the agricultural scientist, the meaning of the word is clear. He uses it to describe that thin upper layer of the earth's crust, a few feet only in thickness, which is responsible for all vegetable growth. The engineer uses it in exactly the same way, since he, too, is concerned with soils at the surface, especially in road and airport work. But he extends its use to include all similar unconsolidated material overlying, to whatever depth, solid rock. Through a possibly unfortunate translation of the German expression *Erdbaumechanik*, he has coined the name 'soil mechanics' to describe his new-found scientific interest in the material for so long disdainfully regarded as mere 'earth' or often as just 'mud'.

It is this name which seems to disturb so many ricultural soil scientists and which now appears be arousing the ire of geologists. But in my very ited geological reading, many references have been ted showing that geologists themselves have for ng used the word 'soil' in exactly the same way engineers—and no modern geological writer yet ppears to have suggested a satisfactory alternative neric name for the unconsolidated part of the rth's crust. Three typical references may be cited, ritish, Canadian and American. In his famous Memoir to the Map of the Strata of England" (1815), Villiam Smith said: "The chances were thought uch against my ever completing it as a map, of the reater part of our island, large enough to show the neral course and width of each stratum of the soil nd minerals, with a section of their proportions, ip and direction . . . ". John William Dawson, in is "Acadian Geology" (Edinburgh, 1855, p. 23), tates that: "The western part of Nova Scotia resents some fine examples of marine alluvial soils". Villiam Henry Brewer, writing on "The Deposition f Clay in Salt Water" (*Amer. J. Sci.*, 29, 1; 1885), ays: "I have carried on a long series of experiments n the sedimentation of clays, and the finer portions f soils and the pulverized rocks . . . ".

Geologists, therefore, would be following a well-stablished tradition if they accept the use of the vord 'soil' as a general description of unconsolidated naterial. By their use of the term 'soil profile', gricultural soil scientists show clearly that they hemselves do not confine the use of the word to hat thin layer with high organic content which they ometimes suggest is the 'proper' use of the word. f 'soil' is to be used to describe the 'C-horizon', ow can the pedologist logically object to the use of he same word in the same way by the engineer, ut used to describe the same material at depths in which the soil scientist has no interest?

Would it not therefore be generally useful to have common understanding as to this well-accepted nd well-established general use of the word 'soil'? he engineer can make his contribution by refraining rom using the expression 'soil profile' to describe the ecord of his sub-surface exploration (as is often done t present). The three disciplines chiefly concerned—ivil engineering, geology and pedology—have so nuch to gain by an interchange of information on oil studies that there would seem to be nothing to ose and much to gain, for the benefit of science in eneral, by the adoption of the very modest suggestion erein advanced.

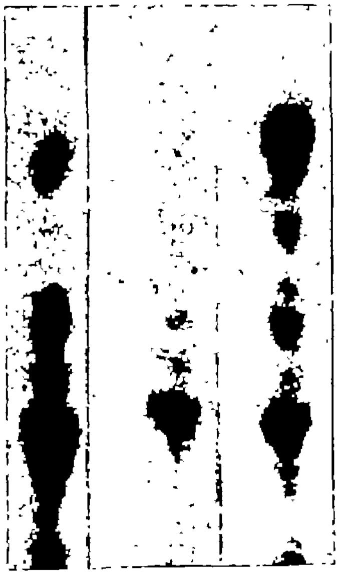
## Identification of Recessive Gene Heterozygotes by means of Paper-Partition Chromatography

PAPER-PARTITION chromatography of tissues of genetically known strains of *Drosophila melanogaster* as well as those of certain plants has shown that each strain gives a constant and distinctive pattern. The chromatographic patterns of heterozygotes carrying recessive genes can be easily distinguished from those of either parental homozygous strain, even though the phenotype of the heterozygote is indistinguishable from that of the homozygous dominant. This is the case for: (*a*) the fluorescent patterns observed under ultra-violet light in the chromatograms of adult *Drosophila melanogaster* heterozygous for the following mutants: bent, eyeless[2], short-vein, spineless-aristapedia, vestigial; (*b*) the ultra-violet-fluorescent and the ninhydrin-positive patterns of root-tip smears of heterozygotes for the mutant male-sterile[3] in tomato[1]; (*c*) the ultra-violet-fluorescent and the ninhydrin-positive patterns of root-tip smears and leaf extracts of heterozygotes for the yellow-green mutant of musk melon[4] (see also chromatogram).



Ninhydrin-positive materials in the chromatograms of smeared root tips of musk melon (genotypes: homozygous wild type; homozygous yellow-green; heterozygous yellow-green). Solvent: 4 *n*-butanol : 5 water : 1 glacial acetic acid

In all cases one-dimensional descending chromatograms were obtained on Whatman No. 1 filter paper, using the following solvents: (*a*) two parts of *n*-propanol and one part of 1 per cent ammonia; (*b*) four parts of *n*-butanol and 1 part of glacial acetic acid, made up with five parts of water. The chemical nature of the substances revealed in the patterns has not been investigated.

The remarkable constancy of the results obtained, the fact that the biochemical patterns of every tissue tested seem to fall under the control of the genotype (with a high degree of independence of feeding and other environmental conditions), and the high degree of chemical specificity evidently imparted by the genotype to the organism suggest that this technique will prove to be of value for the physiological study of gene action and for an analysis of the biochemical basis of individuality. A fuller report will be published elsewhere.

I wish to thank Dr. Charles M. Rick, of the Department of Truck Crops, University of California, Davis, California, and Dr. Thomas W. Whitaker, of the U.S.D.A. Bureau of Plant Industry, Soils and Agricultural Engineering, La Jolla, California, for the plant materials used, and members of the Department of Zoology, University of California, Berkeley, California, for help and facilities provided. The work was carried out while visiting professor at the last-

named institution, in part with a grant from the Rockefeller Foundation.

## Genetic Analysis of Intact Incomplete Asci of Yeast

GENETIC analysis in yeast is usually based on tetrad analysis, that is, on microdissection and culture of the four haploid ascospores from normal four-spore asci. Incomplete asci, that is, containing only one, two or three ascospores, constitute, however, a high proportion of all asci in many crosses. We have investigated whether or not these incomplete asci could be conveniently utilized, without dissection, for genetic analysis; we find that, within limits, Mendelian analysis of one-, two- and to some extent three-spore asci is sufficiently informative to be convenient.

The strains used in the present crosses were nutritional mutants derived by ultra-violet irradiation from strains *B15* and *C24–135* of *Saccharomyces cerevisiae* kindly supplied by Prof. B. Ephrussi. They were heterothallic, practically never producing asci in cultures derived from single ascospores. The crosses reported here were always carried out by placing two haploid cells of opposite mating type next to one another in a hanging drop, observing the formation of the zygote and isolating the diploid derived from it.

One-, two- or three-spore asci formed by these diploid strains were isolated individually and germinated intact on a nutrient agar medium. The cells from the colonies so obtained were analysed for ploidy and genotype. The genetic markers used, besides mating type, were either or both of the following monogenic differences in nutritional requirements: *AD/ad*, independence of, versus requirement for, adenine; *TRYP/tryp*, independence of, versus requirement for, tryptophane.

*One-spore asci.* Forty one-spore asci were isolated from a diploid α *ad* // a *AD*. Twenty-two germinated, all producing haploid strains, and eighteen of these were of *a* mating type. Thus, about 80 per cent of the α mating type ascospores did not produce colonies. It is not yet known whether the low viability of these ascospores is due to the mating type allele itself or to some closely linked locus. The normal formation of diploid colonies from two- and three-spore asci (see below) shows that this low viability does not manifest itself in the heterozygote or in the haploid ascospore if the latter fuses immediately with one of opposite mating type. Of the twenty-two haploid strains obtained, thirteen were *AD* and nine *ad*; that is, the two alleles segregated in ratios not significantly different from 1 : 1; there is thus no evidence of close linkage between this locus and the mating type locus. The results with one-spore asci show that the single spore represents one of the four products of meiosis.

*Two-spore asci.* Intact two-spore asci gave origin on germination either to colonies made up only of diploid cells all of one kind, or to colonies made up only of haploid cells which could be all of one type or of two types. Diploid colonies arise when the two spores are of opposite mating type; haploid colonie when the two spores are of the same mating type

Table 1. COLONIES ORIGINATING FROM INDIVIDUAL TWO-SPORE ASC

(*A*) Two spores of complementary mating types: colonies contain ing only diploid cells.

Cross α *ad* // a *AD*

| | Phenotypes *AD* | *ad* | Tota |
|---|---|---|---|
| No. of colonies: | | | |
| Obtained | 66 | 11 | 77 |
| Expected (5 : 1 ratio) | 64·2 | 12·8 | |

Cross: α *TRYP* // a *tryp*

| | *TRYP* | *tryp* | Tota |
|---|---|---|---|
| No. of colonies: | | | |
| Obtained | 36 | 6 | 42 |
| Expected (5 : 1 ratio) | 35 | 7 | |

Cross: a *ad TRYP* // α *AD tryp*

| | *AD TRYP* | *AD tryp* | *ad TRYP* | *ad tryp* | Tota |
|---|---|---|---|---|---|
| No. of colonies: | | | | | |
| Obtained | 30 | 3 | 3 | 1 | 37 |
| Expected (25 : 5 : 5 : 1 ratio) | 25·7 | 5·1 | 5·1 | 1 | |

$\chi^2 = 2·5 \quad p = 0·45.$

(*B*) Two spores of same mating type: colonies containing onl haploid cells (only a mating type analysed).

Cross α *ad* // a *AD*

| | Phenotypes in sample of cells: all *AD* | *AD* and *ad* | all *ad* | Tota |
|---|---|---|---|---|
| No. of colonies: | | | | |
| Obtained | 5 | 10 | 4 | 19 |
| Expected (1 : 4 : 1 ratio) | 3·2 | 12·7 | 3·2 | |

$\chi^2 = 1·8 \quad p = 0·40.$

Expected ratios are based on the assumption of free recombinatio between all the markers used and between them and their centromere

Table 1 shows the classification of the colonie obtained from two-spore asci in three crosses in whic only gene *AD/ad*, only gene *TRYP/tryp* or both respectively, were segregating, besides mating type The results show that the two ascospores of two-spor asci represent two out of the four haploid product of meiosis, and provide no evidence of linkage between the three loci involved in the crosses.

*Three-spore asci.* Individual colonies from intac three-spore asci are expected to contain two kind of cells: diploid, resulting from fusion of two ascospores of complementary mating type, and haploid resulting from the odd ascospore. In fact, about hal the colonies obtained from three-spore asci were foun to contain only diploid cells, presumably because i the other half the odd spore, which should have given origin to haploid cells, was of α mating type and faile to germinate (see Table 2). The diploid cells from each ascus have been invariably found to be of on type, confirming that usually two ascospores of complementary mating type fuse on germination without first dividing. Whether this conclusion is of general validity or is the consequence of the poor viability of the α mating type cells in the present crosses remains to be seen. The results show that the three

Table 2. COLONIES ARISING FROM INDIVIDUAL THREE-SPORE ASCI
CROSS α *ad* // a *AD*

| Phenotypes of Haploid cells | Diploid cells | No. of colonies |
|---|---|---|
| a *AD* | *AD* | 5 |
| | *ad* | 0 |
| a *ad* | *AD* | 4 |
| | *ad* | 0 |
| α *AD* | *AD* | 0 |
| | *ad* | 0 |
| α *ad* | *AD* | 0 |
| | *ad* | 0 |
| Not present | *AD* | 3 |
| | *ad* | 2 |
| | Total | 16 |

| | | Phenotypes *AD* | *ad* | Total |
|---|---|---|---|---|
| Diploids: | Obtained | 14 | 2 | 16 |
| | Expected (5 : 1 ratio) | 13·3 | 2·7 | |
| Haploids: | Obtained | 5 | 4 | 9 |
| | Expected (1 : 1 ratio) | 4·5 | 4·5 | |

pores of three-spore asci represent three out of the four products of meiosis.

The present work indicates that Mendelian analysis, as distinct from tetrad analysis, is possible in yeast, and in certain cases it is labour saving.

## Absorption of Water by the Egg of the Garden Chafer, *Phyllopertha horticola* L.

Many insect eggs absorb water from the environment[1]. Absorption usually occurs over a limited period during the early stages of development. The mechanism of the control of absorption is being studied in the egg of the garden chafer.

In Nature, the female chafer lays her eggs in June; about the middle of July the larvæ hatch and begin to feed on the grass roots. For 3¼ months the grubs feed and grow, moulting twice. The full-grown third instar larva goes into hibernation about the end of October, resting in a small cavity 3–5 in. deep in the soil. Pupation occurs towards the end of April and the beetle emerges from the pupal skin at the end of May. After staying in the hibernation cavity for a few more days, to complete development, the adult emerges from the soil to mate. The female returns to the soil to lay her eggs.

When laid, the egg is usually a white prolate spheroid, weight 1 mgm., length 1·5 mm. and diameter 1 mm. approximately. On the third day after laying, at 20° C. and 100 per cent relative humidity, the egg begins to absorb water and by the eighth day reaches a weight of 3 mgm., measuring about 2 mm. × 1·5 mm. The weight then remains at that level until the larva hatches on the twentieth day.

The absorption period, from the third to the eighth day, is accompanied by changes in the rate of loss of water of the egg when desiccated. On the first day after laying, the egg loses water (in 0 per cent relative humidity) at the rate of 1 mgm./sq.cm./hr. On the second day the rate of water loss increases, rising to a maximum, on the fifth day, of about 20 mgm./sq.cm./hr. Thereafter the rate falls and by the tenth day has dropped to 0·7 mgm./sq.cm./hr. It is well known that insect-covering membranes show asymmetry in that water passes across them more rapidly in one direction than the other[2]. Thus the rate at which the egg loses water tells us little about the rate at which water is able to pass in through the egg shell. However, changes in rate of loss of water will reflect changes in permeability to inward flow of water.

Changes have also been observed in the thickness of the egg shell. The shell of the new-laid egg is about 8 µ thick. By the end of the absorption period the shell is nearly 15 µ thick. This increase may perhaps be a swelling of the shell material itself, but seems more likely to be due to the addition of material by the embryo.

These observations suggest a possible mechanism by which the uptake of water is regulated: the egg is laid down having a relatively waterproof layer in the shell. This is broken down by the developing embryo; the egg can then absorb water apparently passively due to its high osmotic pressure. When the egg has swollen to its full size, the shell is re-waterproofed by the embryo and absorption stops.

## Nocturnal Mating in *Tæniorhynchus* (*Mansonioides*) *uniformis* (Theobald)

Mating in *Tæniorhynchus* (*Mansonioides*) *uniformis* (Theobald) was observed taking place on the night of December 7, 1951, between 18.30 hr. and 22.30 hr., while all-night trapping of mosquitoes was in progress at a cattle-shed in a village on the outskirts of Colombo. On this night it was quite dark by 18.15 hr., but for the light of the moon which was two days after the first quarter. Mating activity took place in three stages. In the first and third stages, which lasted from 18.30 hr. until 19.30 hr. and during 20.30 hr.–22.30 hr. respectively, mating was in active progress. In between these two periods of considerable activity there occurred a lull from 19.30 hr. until 20.30 hr., during which far fewer pairs of mosquitoes were observed copulating, and relatively few males were found coming into the trap. But at no time during this period of four hours was mating not in progress, and 292 females and 195 males were caught; these numbers represented only a small proportion of *T. uniformis* in the trap, for owing to great activity among the mosquitoes, catching was seriously interfered with. No mating occurred after 22.30 hr.

Three types of mating behaviour were observed occurring simultaneously. In the first, males were copulating with blood-fed females which were resting on the trap-net. In the second, males and females were seen flying *in copulo*, the females being in the lead, while in the third type males were seen to copulate with females in flight.

Although observations have been carried out at this site on more than a hundred occasions, no swarming of males of *T. uniformis* has ever been encountered, while mating only occurred on this particular night. These observations on *T. uniformis* appear to be the first record of nocturnal mating of a mosquito in Nature. It took place over a period of four hours and in the absence of any swarming by the males.

A more complete account will be published elsewhere.

Colombo 8. Sept. 17.

## Absence of the Sickle Cell Trait in the Bushmen of South-West Africa

During the course of a general survey of the black races of southern Africa for the sickle cell trait—the results of which will be published elsewhere—an opportunity arose of examining blood specimens from 118 Bushmen. Fifty-eight specimens were obtained from Barakwenga or River Bushmen living in the western section of the Caprive Zipfel in the north-east of South-West Africa. The remainder were from south of the Okavango River near the western border of Bechuanaland.

Whole blood specimens were collected in sterile 'Venules' or sterile corked specimen tubes and sent to Johannesburg by air for examination, where they arrived about a week after collection. Sixty samples collected in specimen tubes arrived showing a moderate degree of hæmolysis, whereas the specimens collected in the 'Venules' arrived in excellent condition. The bloods were tested for the sickle cell trait using the sodium hydrosulphite method of Williams and Mackey[1] or the sodium meta-bisulphite method of Daland and Castle[2]. Fifteen specimens were tested by both these methods and by the sealed coverslip method read after 24 hr. Fifty-eight specimens were examined in parallel with specimens of known sickle cells in order to assess the efficiency of the reducing agent used. These controls invariably showed marked sickling within 30 min. The specimens of Bushmen bloods were examined 30, 60 and 90 min. after adding the reducing agent. All of 118 specimens examined were found to be negative.

The age- and sex-distribution of fifty-eight specimens is shown in the table. The youngest individual tested was a male aged five years— the oldest was a male aged fifty-six. The remaining sixty specimens were random samples obtained from the population of the area. At the same time, 119 specimens of blood from members of the Mpukushu tribe living in the Western Caprive Zipfel were also examined with similar negative results.

| Age in years | Males | Females | Total |
|---|---|---|---|
| 0–5 | 1 | 1 | 2 |
| 6–10 | 8 | 5 | 13 |
| 11–15 | 2 | 5 | 7 |
| 16–20 | 4 | 2 | 6 |
| 21–25 | 2 | 5 | 7 |
| 26–30 | 3 | 8 | 11 |
| 31–35 | – | 5 | 5 |
| 36–40 | 3 | 1 | 4 |
| 41–45 | 1 | 1 | 2 |
| 46–50 | – | – | – |
| 51–55 | – | – | – |
| 56–60 | 1 | – | 1 |
| Total | 25 | 33 | 58 |

The ethnological importance of the absence of the sickle cell trait in the Bushman, contrasting with the high incidence of the trait in the black races of Central, East and West Africa, and especially in the Pygmies of Central Africa[3], will be discussed elsewhere.

I wish to thank Dr. Kuschke, regional health officer of the Okavango area, who collected these specimens.

## Tainting of Tobacco by a Dichloropropene–Dichloropropane Soil Fumigant

I wish to refer to the letter under the above title from Dr. C. J. Shepherd in *Nature* of December 20, p. 1073. The work mentioned was carried out while Dr. Shepherd was employed by the Tobacco Pest Control Research Scheme here and was submitted to the Executive Committee, of which I was chairman. After very full consideration it was decided that tl results of this particular investigation should not l published, as it was of a preliminary nature ar carried out on a commercial crop on a farm. l other words, no control was possible and it is eve conceivable that the tainting resulted from incorre use of the fumigant. The Tobacco Pest Contr Research Scheme has ceased operations and its ac ivities have been handed over to the Tobacco Researc Board, which has well-designed experiments in pr gress to check this using both dichloropropene dichloropropane and ethylene dibromide.

I appreciate that Dr. Shepherd's communicatio is in the nature of a preliminary notification of wor in progress, and this could have been equally we achieved by omitting the first paragraph. I am cor cerned, however, lest a completely wrong impressio be given regarding the quality of Rhodesian tobacc The estimate of five per cent of the crop being affecte is a very wild guess, and the considered opinion c authorities here is that the little tainting noticed wa due either to failure to follow instructions for th use of the fumigant, or to the abnormal wet weathe experienced at time of planting.

## A Riss-Würm Interglacial Deposit at Ipswich

During recent months, excavations for new sewage works near Ipswich have exposed lacustrine deposits, between the Upper Chalky Boulder Clay (Gipping) and contorted beds, which there is every reason to believe are referable to the Würm glaciation.

The deposits, consisting of silt, calcareous clay and peaty detrital mud, are cut into and are overlaid with mixed materials which elsewhere in the district can be demonstrated to be equivalent to a 'till' with derived masses of Gipping C.B.C. included. There is a very rich molluscan fauna with which are associated bones and teeth of field mice, voles, frogs or toads, fishes and the European freshwater tortoise (*Emys orbicularis* L.). Bison and *Elephas primigenius* are indicated by fragmentary remains; but the use of mechanical excavators results in breaking up the bones of the larger fauna, few of which are found. A split deer radius bearing cuts suggests nearby human occupation.

It is evident these deposits are contemporary with the well-known Stoke Tunnel Beds examined by the late Miss N. F. Layard, where mammoth and *Emys* were also discovered together with *Bos primigenius*, *Cervus elaphus*, *Equus caballus*, and lion, bear, wolf, fox, etc.

The molluscs and pollen grains are being studied. A number of coleopteran fragments are available for examination.

Harold E. P. Spencer

High Street,
Ipswich.
March 9.

# FORTHCOMING EVENTS

## Saturday, March 28

ASSOCIATION OF CLINICAL BIOCHEMISTS (at the Postgraduate Medical School of London, Ducane Road, London, W.12), at 2.30 p.m. —Inaugural Meeting.

## Monday, March 30

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, Victoria Embankment, London, W.C.2), at 5 30 p m.—Discussion on "Use and Abuse of Research" (to be opened by Dr. S. Whitehead).

SOCIETY OF ENGINEERS (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5.30 p m.—Dr. R. Week: "Structural Failure and What we Learn from It".

ROYAL GEOGRAPHICAL SOCIETY (at 1 Kensington Gore, London, S.W.7), at 8.15 p.m —Dr. E. Wyss-Dunant: "Swiss Everest Expedition, 1952" (Dickson Asia Lecture). (Admission by special ticket only.)

## Tuesday, March 31

SOCIETY OF INSTRUMENT TECHNOLOGY (joint meeting with the CONTROL SECTION, at Manson House, 26 Portland Place, London, W.1), at 6 30 p.m —Dr. G. L. d'Ombrain "The Presentation of Control Theory and the Training of Control Engineers".

ROYAL AERONAUTICAL SOCIETY (at 4 Hamilton Place, London, W.1), at 7 p m.—Mr. W. E. Gray: "Experimental Work on Boundary Layer Flow".

## Wednesday, April 1

SOCIETY OF PUBLIC ANALYSTS AND OTHER ANALYTICAL CHEMISTS (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 7 p.m.—Discussion on "The Determination of Small Amounts of Lead in Foods and Biological Materials".

# APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned.

ANALYST, Grade IVb (Int), for duties concerned mainly with analysis of agricultural products in advisory and experimental work—The Secretary, Edinburgh and East of Scotland College of Agriculture, 13 George Street, Edinburgh (April 4)

EDUCATIONAL PSYCHOLOGIST (with a degree in psychology)—The County Medical Officer, County Hall, Kingston-upon-Thames, Surrey (April 4).

ASSISTANT LECTURERS IN THE DEPARTMENTS OF BIOLOGY, CHEMISTRY, PHYSICS—The Warden and Secretary, Royal Free Hospital School of Medicine, Hunter Street, London, W.C.1 (April 10).

SOIL CHEMIST (with a degree in science, preferably honours, and an interest in chemistry relating to soils or in physical chemistry) at Auchincruive—The Secretary, West of Scotland Agricultural College, 6 Blythswood Square, Glasgow, C.2 (April 10).

ASSISTANT LECTURER IN ANIMAL PHYSIOLOGY—The Secretary and Registrar, The University, Southampton (April 11).

STEROID CHEMIST TO THE ENDOCRINE LABORATORY at the Chelsea Hospital for Women—The Secretary, Queen Charlotte's Hospital, 339 Goldhawk Road, London, W.6 (April 11).

ASSISTANT EXPERIMENTAL OFFICER for laboratory and field work in plant pathological research on diseases of the potato—The Secretary, Agricultural Research Council, 15 Regent Street, London, S.W.1 (April 15).

LECTURER IN INORGANIC CHEMISTRY (with experience and interest in research in some branch of inorganic chemistry)—The Registrar, King's College, Newcastle-upon-Tyne (April 15).

ENGINEER OR PHYSICIST IN THE MECHANICAL ENGINEERING DEPARTMENT, Royal Aircraft Establishment, Farnborough, to carry out analytical and experimental work on problems in connexion with cooling of high-speed aircraft—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting A 67/53A (April 16).

INSPECTOR (Salmon and Freshwater Fisheries) IN THE MINISTRY OF AGRICULTURE AND FISHERIES (candidates must hold at least a second-class honours degree in natural science with zoology or biology as a principal subject, or in some other natural science and have specialized subsequently in zoology or biology)—The Civil Service Commission, Scientific Branch, Trinidad House, Old Burlington Street, London, W.1, quoting S.101/53 (April 16)

SENIOR GEOLOGISTS in the Atomic Energy Division of the Geological Survey—The Civil Service Commission, Scientific Branch, Trinidad House, Old Burlington Street, London, W.1, quoting S.169/53 (April 16).

ASSISTANT LECTURER IN THE DEPARTMENT OF PHYSICS—The Registrar, University College, Aberystwyth (April 18).

ASSISTANT ZOOLOGIST (with an honours degree in zoology and a knowledge of botany) for work in connexion with investigations on potato root eelworm—The Secretary, School of Agriculture, Cambridge (April 20).

LECTURERS OR ASSISTANT LECTURERS IN AGRICULTURE, AGRICULTURAL ENGINEERING and AGRICULTURAL CHEMISTRY, at the University College of Khartoum, Sudan—The Secretary, Inter-University Council for Higher Education in the Colonies, 1 Gordon Square, London, W.C.1 (April 20).

ASSISTANT FUEL ENGINEER (with a good B Sc., mechanical engineering or fuel technology, or equivalent qualification) in the Experimental Mobile Testing Unit of Production Department—The National Coal Board, Establishments (Personnel), Hobart House, Grosvenor Place, London, S.W.1, quoting TT/609 (April 22).

ASSISTANT LECTURER OR LECTURER IN THE DEPARTMENT OF GEOGRAPHY—The Registrar, University College of North Staffordshire, Keele, Staffs. (April 22).

CHAIR OF MORBID ANATOMY at Charing Cross Hospital Medical School—The Academic Registrar, University of London, Senate House, London, W.C.1 (April 23).

ASSISTANT LECTURER IN APPLIED MATHEMATICS—The Registrar, University College, Hull (April 24)

READERSHIP IN AGRICULTURAL ECONOMICS at Wye College—The Academic Registrar, University of London, Senate House, London, W.C.1 (April 24)

SCIENTIST, Grade II (with a good honours degree, or equivalent, and at least three years postgraduate research experience in telecommunications, automatic control or electromagnetic theory) at the Central Research Establishment II, Worton Road, Isleworth—The National Coal Board, Establishments (Personnel), Hobart House, Grosvenor Place, London, S.W.1, quoting TT/608 (April 25).

ASSISTANT LECTURER IN GEOLOGY (with special qualifications in petrology)—The Registrar, The University, Manchester 13 (April 27).

ASSISTANT LECTURER OR LECTURER IN PHYSICS—The Registrar, The University, Leeds 2 (April 27).

ASSISTANT (Scientific) for histological and general biological work—The Director, The Laboratory, Citadel Hill, Plymouth (April 30)

LECTURER IN MECHANICAL ENGINEERING (special experience in heat engines and/or fluid mechanics an advantage) at the University of Sydney—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (April 30).

ASSISTANT LECTURER OR LECTURER IN CHEMISTRY (with special interest in inorganic or analytical chemistry), an ASSISTANT LECTURER IN CHEMISTRY (with special interest in physical chemistry), and an ASSISTANT LECTURER IN CHEMISTRY (with special interest in organic chemistry)—The Registrar, The University, Sheffield (May 1)

ASSISTANT LECTURER IN CHEMISTRY—The Registrar, The University, Manchester 13 (May 6).

LECTURER OR ASSISTANT LECTURER IN PHYSICAL OR ORGANIC CHEMISTRY—The Secretary and Registrar, The University, Southampton (May 9).

RESEARCH OFFICERS (Chemical Engineers, with B.Sc. honours or B.Sc. (Eng.) degree in chemical engineering or equivalent qualification) for process development work in the National Chemical Research Laboratory, Pretoria—The Secretary-Treasurer, South African Council for Scientific and Industrial Research, P.O. Box 395, Pretoria, South Africa (May 11).

LECTURER IN BOTANY at the University of Melbourne—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C 1 (May 15)

LECTURER IN THEORETICAL PHYSICS—The Registrar, The University, Liverpool (May 15).

SENIOR and JUNIOR FELLOWSHIPS—The Director, Atomic Energy Research Establishment, Harwell, Didcot, Berks (May 18).

LECTURER (with a university degree in mining and a first-class colliery manager's certificate) IN MINING—The Registrar, The University, Leeds 2 (May 29).

RESEARCH ASSISTANTS for work (*a*) on the physical and chemical aspects of selective flotation (candidates should hold a good honours degree in physics or physical chemistry), and (*b*) on mining research problems, either in the Department's laboratories or, where necessary, in the mines (candidates should hold a good honours degree in mining or in civil or mechanical engineering)—The Registrar, The University, Leeds 2 (May 29)

ASSISTANT (with an honours degree in electrical engineering, and some research experience desirable) IN THE DEPARTMENT OF ENGINEERING—The Secretary, The University, Edinburgh (June 1).

FOULERTON RESEARCH FELLOWSHIP IN MEDICAL SCIENCE—The Assistant Secretary, Royal Society, Burlington House, Piccadilly, London, W.1 (June 1).

BOTANIST OR PLANT PHYSIOLOGIST (with honours degree) to assist in the investigation of the uptake of nuclear fission products by marine algae—The Secretary, Institute of Seaweed Research, Inveresk, Midlothian.

DESIGN ENGINEERS to undertake duties of project engineers, including the design and layout of special plant and equipment—The Ministry of Supply, Division of Atomic Energy (Production), Risley, Warrington, Lancs, quoting 440.

ELECTRICAL ENGINEERING ADVISER in Ceylon under the Colombo Plan, to advise on the planning, construction and operation of hydro-electric and thermal power stations—The Ministry of Labour and National Service, Almack House, 26 King Street, London, S.W.1, quoting A 12/CE.300/52.

EXECUTIVE ENGINEER, Public Works, Electricity and Land Survey Department, Zanzibar—The Director of Recruitment, Colonial Office, Great Smith Street, London, S.W.1, quoting CDE 112/10/01.

EXPERIMENTAL OFFICER IN THE RADIO RESEARCH ORGANIZATION, Teddington, for abstracting scientific and technical articles on radio research and development—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting D.x68/52A

GRADUATE IN CHEMISTRY OR PHYSICS to undertake abstracting of technical literature, preparation of literature surveys and other technical intelligence work—The Secretary, Research Association of British Rubber Manufacturers, 105 Lansdowne Road, Croydon.

LECTURER OR ASSISTANT LECTURER IN THE DEPARTMENT OF CIVIL ENGINEERING—The Secretary and Registrar, The University, Southampton

MECHANICAL ENGINEER IN THE PUBLIC WORKS DEPARTMENT, Malaya—The Director of Recruitment, Colonial Office, Great Smith Street, London, S.W.1, quoting CDE.112/60/08

ROBERT CORMACK FELLOWSHIPS IN ASTRONOMY—The General Secretary, Royal Society of Edinburgh, 22 George Street, Edinburgh 2.

SCIENTIFIC OFFICER (non-medical) IN THE DEPARTMENT OF HAEMATOLOGY—The Superintendent, Royal Hospital, West Street, Sheffield 1.

SENIOR and JUNIOR positions in the DEPARTMENTS OF ANATOMY, PHARMACOLOGY and PHYSIOLOGY, HEBREW UNIVERSITY—Prof. Samson-Wright, Middlesex Hospital Medical School, London, W 1.

STATISTICIAN IN THE DEPARTMENT OF AGRICULTURE, Kenya, to advise on the design of field and other experiments conducted by the Department, including sampling investigations and surveys, and to assist in the statistical analysis of results—The Director of Recruitment (Colonial Service), Colonial Office, Sanctuary Buildings Great Smith Street, London, S.W.1, quoting CDE.63/7/03.

# REPORTS and other PUBLICATIONS

# EXPANSION OF TECHNOLOGICAL AND TECHNICAL EDUCATION

MR. BOYD-CARPENTER'S written answer to questions in the House of Commons on January 29 regarding Government plans for the establishment of a technological university made it clear that the Government has no intention of establishing an entirely new institution of that type. Instead, it has decided to build on an existing foundation, and the decision to expand the Imperial College of Science and Technology in London to twice its present size has the advantage not merely of being less costly, but also of minimizing the difficulties and delays in assembling teaching staff of the high calibre essential. There is the further merit that the Imperial College already possesses a firm basis of prestige to which it will now be expected to add.

While the statement claims that this decision is in pursuance of the policy already announced by the Government and that the Government proposes also to make resources available for further developments in other parts of Great Britain, this claim must be firmly challenged. The Chancellor of the Exchequer has, it is true, already asked the University Grants Committee to advise him where such further resources might be most usefully deployed, but that the choice of the Imperial College comes seven months after Mr. Butler's announcement last June is suggestive of absence of a policy rather than pursuance of one. There is no indication as to what guidance has in the meantime been given to such claimants, for example, as the Royal Technical College, Glasgow, or the Manchester College of Technology, where considerable schemes of expansion are contemplated or in progress, nor is there any indication that the Government appreciates the importance of relating technological and technical education.

Perhaps the clearest proof that the Government has a policy for higher technological education would be an unequivocable announcement that the responsibility for it had been placed fairly and squarely on some one body, as the Advisory Council for Scientific Policy has already recommended. Apparently the Government proposes to use the University Grants Committee for that purpose; by according that body the *de jure* recognition in place of the merely *de facto* recognition it already enjoys, the Government could well establish the *bona fides* of its policy, and at the same time the position of the technical colleges at Glasgow and Manchester, both of which are already included in the returns from the University Grants Committee, might be resolved.

But the question what other institutions of higher technological education should be expanded is no more a matter for piecemeal decision than the choice just announced. The expansion of technological education in Great Britain must obviously be determined by the extent of the national resources, financial and material, as well as the man-power situation. It should equally be determined by a wide and clear view of national needs; and present concern arises in part from the impression gained from a good deal of scattered evidence that neither the present Government nor its predecessor has had any such view.

The Government appears to accept the prevalent view that while Britain is pre-eminent in fundamental research she is lacking in its industrial application, and proposals to expand technological education are the immediate consequence. Any real policy to this end must, however, be concerned equally with the expansion of technical education, and with the effective use to be made of the new graduates in technology which the expansion of technological institutions would provide. There is as yet little evidence of an increased demand from British industry for their services as technologists, nor could their services as such be fully utilized without an appropriate expansion in the numbers of technicians, which are required in far greater numbers.

For this reason alone, a sound policy for the expansion of technological education can be framed only in line with one for the expansion of technical education. In the upgrading of technical colleges to provide them with the resources and the conditions of academic freedom that are essential for such work, the danger is not simply of spreading available resources too thinly. The effect on the resources for technical education must also be considered, quite apart from the question, on which differing views are held, as to whether technological and technical education can be given efficiently in the same institution.

Nor can it be assumed that the expansion of technological education is all that is required to provide Britain with the technologists she requires. As Dr. D. W. Hill pointed out in a recent article, a better distribution of the existing scientific personnel may provide a partial solution. Stress has been laid by the Advisory Council for Scientific Policy, as well as by Dr. R. L. Meier in an article, "Research as a Social Process", in the *British Journal of Sociology* (1951), on the lesser esteem which technological work enjoys in Great Britain. Attention to this factor, both in the schools and elsewhere, is undoubtedly required, whether or not it is necessary to make the financial rewards offered for technological work more attractive.

The point to which Dr. Hill directs more particular attention is the lesser use made of the technologist in high managerial positions in Great Britain compared with the United States. There it is customary for the executive heads of large industrial concerns to be technologists, particularly engineers. Dr. Hill notes that every president of the great Du Pont de Nemours concern since the First World War has been either a chemist or an engineer. Men so trained naturally attach high importance to the technological standards of their staff, and part of the problem of increasing the supply of technologists for Great Britain may well be to discover why the demand for them here is not more insistent.

There is a further reason why this requires consideration in elaborating a policy for technological education. Evidence has been provided in some of the productivity team reports of the Anglo-American Council on Productivity that leaders in British industry are not sufficiently receptive to technological advances. A large proportion of British industry consists of smaller firms which may not employ anyone competent to assess the significance for industrial development of new scientific or technological advance.

No matter what care is taken in the existing technological institutions of Great Britain and in their expansion to see that students are given the wide training that fits them to occupy ultimately high administrative positions, that of itself will not meet the difficulty of the smaller firm. A change of outlook on the part of industry generally is also likely to be required. How far government action could foster a change in the climate of opinion or encourage the wider spirit of adventure in industry for which Sir Henry Tizard pleaded in his Messel Memorial Lecture is a matter of opinion; but it is at least a factor of which the Government must take careful account in formulating a policy for technological education. Such a policy cannot bear its full fruits unless the Government does all in its power to remove hindrances or obstacles to enterprise, and to encourage the adventurous acceptance of the challenge of the times and the exploitation of new techniques and products and the discarding of outmoded methods and obsolete plant.

This aspect was not dealt with by Lord Halsbury when he reviewed the controversy over higher technological education in addressing the Institution of Chemical Engineers in Manchester on January 23. He agreed that the expansion of technological education meant limitation of resources available for other types of education and for other purposes, but he favoured a steady expansion of the technological faculties of our universities to an extent when the supply of technologists slightly exceeded supply. The surplus, he thought, would be absorbed in administrative positions; but it may be recalled that Prof. R. Peers, at a recent conference at Nottingham on industry and the universities, took a similar view regarding the absorption of arts graduates as administrators in industry.

There can be little doubt that the expansion of the universities, and especially the steady increase in the proportion of students receiving assistance in some way or other from public funds, has markedly affected the quality of direct recruitment from the schools to industry. Industry will perforce come to rely increasingly on entry from the universities to fill its managerial and more responsible positions; but it scarcely seems sound so to plan the expansion of higher technological education as to provide technologists in excess of a reasonable assessment of the demand for technologists as such. It is as implicit in much current discussion of university education as in the discussions on the content of technological education that training in institutions of that type should provide, not simply professional skill and knowledge, but first of all the capacity for clear and independent thought, the ability to tackle a problem, initiative and a sense of perspective and values, as well as the readiness to accept responsibilities. These are the qualities which will determine the graduate's capacity to fulfil positions of responsibility in middle life and later, and they can be imparted as much on the arts side as on that of science and technology, provided the arts courses are attuned to the general problem of living in the technological society of to-day.

For that reason Lord Halsbury's suggestion appears to be unsound, and the expansion of technological education should be planned rather in accordance with factual requirements, so far as they can be ascertained. It does not appear that the Government has attempted any recent assessment of the real needs: that contained in Sir Ewart Smith's address at the British Association meeting in Birmingham in 1950 certainly should be taken further to provide a basis for policy. Some such quantitative estimate might provide one means of minimizing further controversy over the institutions to be selected for development, the scale of expansion and the types of technology to be included.

A very reasonable summary of the present situation and measure of agreement was given by Colonel B. H. Leeson in an address to the Institution of Electrical Engineers last October. He visualized the expansion of higher technological education as concentrated on a regional basis in a few selected larger colleges provided with first-class accommodation and staff, and stimulated by adequate opportunities and resources for research. The selected institutions would enjoy academic freedom under self-governing representative administration, and would not come under local education authorities. They would have facilities for postgraduate work, but would be expected to earn their prestige.

The small body which should be set up by the Government to select and to guide the colleges when chosen, in consultation with professional bodies, learned societies and industry, could well be a committee of the University Grants Committee; but until some such step has been taken the Government cannot claim to have a policy for technological education. It is emphatically not a matter primarily for the Minister of Education, though that Ministry will be required to renounce its authority over the selected colleges, and must also be concerned with the adjustments in the technical education that are involved. The technicians required, as Col. Leeson pointed out, outnumber the technologists by at least five to one, and whether or not the training of technicians and technologists can usefully and efficiently proceed side by side, at least in the selected institutions, the provision of facilities for training technicians will remain the responsibility of the Ministry of Education. Equally, the expansion of those facilities must match that of technological education. Parsimony or unwise retrenchment here could go far to thwart the expansion of technological education.

That due weight must be given to the content of technological education in planning its expansion, and especially to the exact technologies which are to be included, is indicated by the nature of the claims which have been advanced for the institution of new faculties such as pharmaceutical engineering science. Discussions at the conferences on industry and the universities, arranged by the Federation of British Industries, indicate that little support for such extravagances is likely to be forthcoming from the industrial side. That they should be advanced at all is a further reason for urging the early establishment of some agreed authority with the clear responsibility for encouraging the development of higher technological education.

Such a step in itself will not remove all difficulties in the way of co-ordination. While, for example, the Royal Technical College, Glasgow, has an independent board of governors and the local authority exercises no control, to develop further higher technological education there under the University Grants Committee would involve a transfer of responsibility from the Scottish Education Department. The position of another claimant, the College of Technology, Manchester, is more complicated. This includes the faculty of technology of the University of Manchester, and the College has received Government grants for more than forty years in the same way as other universities and university colleges. Nevertheless, the College is still subject to local authority control, though this need not perhaps be the main obstacle to its development as one of the few regional centres for the expansion of higher technological education. That obstacle is to be found rather in the limitations on its expansion placed by its equally important work in training technicians. The present plans for the expansion of the Manchester College of Technology contemplate the decentralization to subordinate centres of the more elementary work. This may give sufficient room for the development of the advanced work, and at the same time provision for part-time students from industry should minimize any drawbacks the partial divorce of technical from technological education might entail.

Quite apart, however, from the question whether it is wise to attempt to carry out technical and technological education side by side in the same institution, even when physical considerations such as siting do not impose limitations on expansion, the separation of technical and technological education should be determined on practical rather than on theoretical grounds, but in accordance with policy rather than by piecemeal decisions. Even on technical education the Minister of Education has given no signs as yet of having a policy, though formulation of policy is the first step towards the wise and efficient use of national resources. Such a policy must take account, not only of the balance between the numbers of technicians and technologists required by industry, of the probable demand for the services of both, of the resources and distribution of existing institutions, and the claims which expansion must make on available national resources, it must also take account of the well-attested gap which exists in Great Britain between pure and applied scientists and of the general impact of technology on society, and the stresses and needs which are liable to develop in consequence. Ultimately, it is concerned with the rate of technological change and its general effects; and at a time when a prime reason for urging the expansion of technological education is to promote the economic development of Great Britain, it is the more important that heed should be given, in planning both our policy of technical education and its content, to the effects on society.

# KINEMATIC RELATIVITY AND THE CREATOR

Modern Cosmology and the Christian Idea of God
Being the Edward Cadbury Lectures in the University of Birmingham for 1950. By E. A. Milne. Pp. vii+160. (Oxford: Clarendon Press; London: Oxford University Press, 1952.) 21*s.* net.

THE late Prof. E. A. Milne had been asked to give a series of ten lectures on the Edward Cadbury Foundation at the University of Birmingham in the autumn and winter of 1950–51. The manuscript of these lectures was completed only a few days before his sudden death in September 1950, and the lectures are now published in book form, having been edited by his former pupil, Dr. G. J. Whitrow.

The original intention of the founder of the lectures was that they should be concerned with the relations, past, present and future, of Christianity to civilization and culture. Milne was invited to choose the relationship between cosmology and Christianity to-day. He states that he chose chiefly to discuss his own brand of cosmology because he had no faith in other theories of cosmology. The lectures, therefore, consist in the main of an exposition of kinematic relativity, which, being intended for a general audience, is practically free from mathematics. They provide the only exposition of this theory by Milne himself that can be described as non-technical. In the main, they cover the same ground as his book "Kinematic Relativity", but go beyond that work in giving an account of his last paper on a possible relation between gravitation and magnetism and a revision of his dynamical theory of light.

Kinematic relativity is a deductive theory which, starting from the cosmological principle in its narrow sense and from the basic facts of the dimensionality of space and time, and of the propagation of light, seeks to derive as much information as possible about the universe. The theory has been developed to cover not only cosmology but also a great part of theoretical physics. It employs two different time-scales: the so-called $t$-scale in which the relative motions of the observers are non-zero but unaccelerated, and the $\tau$-scale in which the observers appear to be at rest. The zero of the $t$-scale, which is the instant at which the universe was created, corresponds to negative infinity on the $\tau$-scale. The ordinary dynamical and physical laws employ $\tau$-time, but the $t$-scale is regarded as the fundamental one. Though any statement involving one scale can be transformed into a statement involving the other, statements in $\tau$-measure of anything but local phenomena are strange and unfamiliar. The $\tau$-scale is an ephemeral one, only appropriate to epochs near the present epoch of the observer using it.

Milne considers that the universe started as a transcendental point singularity at $t = 0$. At that instant, the linear dimensions of all atoms, stars and galaxies of every type of configuration must have been zero. Thereupon expansion began, the motions being radially outwards; at any subsequent time the distance travelled by any given particle is proportional to its velocity. Kinematic relativity leads to a unique model universe; Milne argues that this uniqueness implies an absence of rational alternatives in creation and that this is a genuine argument for both the rationality and the oneness of God. He considers that the possibility of constructing a rational system of time-keeping by congruent clocks implies that the universe has been deliberately created.

Kinematic relativity requires the constant of gravitation and Planck's constant to increase proportionally to the age of the universe reckoned from the natural zero of time ($t = 0$). The inverse-square law of gravitation can be put into an invariant form only by those observers in uniform relative motion for whom identical world pictures present themselves. On this subject of gravitation Milne asserts that "The law of gravitation cannot have been created by God by an arbitrary fiat; it is a consequence of the disposition of matter and motion in the Universe, in our $t$-description. God is a geometer in the more extended sense of a mathematician who extends the geometry of static figures of points, lines, and planes to idealised particles in motion".

According to Milne's theory the number of galaxies is infinite, although the space occupied by them is finite. Thus as we get farther and farther from any one galaxy we cannot avoid getting near other galaxies. As the universe expands, it creates the space it needs. But there is no last galaxy; we can never reach the edge. The apparent density of the universe is everywhere finite, but it becomes arbitrarily large at an arbitrarily small distance inside the expanding frontier. The most swiftly receding galaxies will appear, owing to the slowing-down of their clocks, to have been created a very short time ago. Milne will have nothing to do with the concept of continuous creation on the ground that it offers no explanation of how the frames of motion, in which the hydrogen atoms appear sporadically, are created. Nor does he accept the theory of the heat-death of the universe, which was advocated by Eddington and Jeans. He does not regard it as an inevitable consequence of the second law of thermodynamics, when applied to the universe as a whole. It is not possible to make valid propositions about the entropy of all the bodies in the universe because the universe has no final state. "Near its inaccessible frontier, the world will appear ever young, though each individual member will be growing old. There is no need of any appeal to any principle of rejuvenescence. For the universe as a whole has no age and no size, only an age and a size when a particular observer is singled out, at a particular stage of his experience".

Milne considers the evolution of spiral nebulæ. He asserts that the kinematic theory of gravitation goes far towards explaining the spiral form of many of the galaxies; the spiral arms are a consequence of the secular increase of the constant of gravitation. He concludes that the whole course of the evolution of a galaxy is one of interchange of its members with other galaxies. There is an outward drift in the neighbourhood of each nucleus, and the particles are continuously accelerated until they momentarily reach the velocity of light; deceleration then sets in, and each particle eventually comes to rest near a distant nucleus, becoming part of its galactic cloud of gas and dust particles. The galaxies are thus continually losing particles to distant galaxies but at the same time gaining particles from other distant galaxies. These particles when moving with speeds close to that of light are considered by Milne to constitute what we know as 'cosmic rays'.

Milne's discussion leads him to the following conclusions. "Laws of motion are not special creations but are indissolubly connected with the creation of the material content of the universe in the only manner in which such creation could have taken place, namely, by the recognition by the Creator of the impossibility of choosing special velocity frames when there is nothing to distinguish one frame from another, and of the impossibility of effecting the act of creation otherwise than at a point-singularity owing to the impossibility of choosing, unambiguously, simultaneous events separated from one another. Creation, the act, became a more and more difficult process the more we study it, until we see how God the Creator put aside the difficulties by the device of the creation of an infinite universe at a point as an initial point-singularity. . . . For the creation by God of an extended universe would require an impossibility, the impossibility of the fixation of simultaneity in the void—impossibility, that is, to a rational God. The paradox follows that the Deity himself, though in principle all-powerful, is yet limited by his very rationality. With God all things are not possible. This equally rules out the idea of continuous creation of matter everywhere in space, for there would have to be a pre-created space in which the creation of matter could take place; and there would exist a constant, namely the rate of creation of such matter, which could not be rationally accounted for."

Many readers of this exposition of kinematic relativity will not regard these conclusions as justified. But all will find much that is stimulating and thought-provoking in this exposition by its creator of a theory which has provided a searching examination of the concepts of time and space and which has great achievements to its credit. H. SPENCER JONES

## BOTANICAL TAXONOMY

### Taxonomy of Vascular Plants

By Prof. George H. M. Lawrence. Pp. xiii+823. (New York: The Macmillan Company; London: Macmillan and Co., Ltd., 1951.) 60s. net.

THERE has been a great need for an up-to-date and comprehensive handbook on the classification of vascular plants, and botanists all over the world are grateful to Prof. George Lawrence for undertaking to fill the gap. This he has done with notable judgment and skill, and with, inevitably, the expenditure of much time and labour that could no doubt be ill-spared from his research and other activities. As a result, he has produced a volume that will, for many years, be the daily companion of all concerned with the taxonomy of flowering plants and ferns.

The book is divided into two parts. The first, consisting of fourteen chapters (330 pages), deals with what may be broadly described as the principles and practice of systematic botany, while the second part (400 pages) is concerned with individual families, arranged in the sequence of Engler and Diels. There are two appendixes comprising a suggested syllabus for an elementary course in taxonomy, and an illustrated glossary of terms. An excellent single index completes the volume. Prof. Lawrence has chosen to scatter his very valuable bibliographies throughout the book after the relevant sections, and one thus misses the ease of finding a particular reference afforded by a single alphabetical bibliography, coupled with lists of abbreviated references after each chapter; but the saving of space no doubt dictated his choice, and, as it is, the bibliographies, especially those after each family in Part 2, will be one of the most welcome features of the book.

In Part 1 Prof. Lawrence gives excellent accounts of the history of botanical classification, leading to a survey of current systems, and has chapters on geographical distribution, nomenclature, identification, literature, field work and herbarium techniques, and on the writing of monographs, revisions and Floras. But it is probably to the sections on the more controversial aspects of taxonomy that many readers will turn first, for there are very few easily accessible recent summaries on the relationship between classification and phylogeny (Chapter 5), and on biosystematics and experimental taxonomy (Chapter 8). Prof. Lawrence's two chapters are undoubtedly the clearest and most up-to-date treatments so far produced, and show an awareness of many of the subtle difficulties that are so often ignored. In his discussions in phylogeny and taxonomy, however, and on biosystematics, one misses a clear statement of the basic aims of classification in general, and of biological classification in particular, without which the present troubled state of these subjects can scarcely be resolved. The idea that there can ultimately be one comprehensive classification of living things based on all their characters is a very attractive one to the human mind; but the belief that this concept is chimaerical is slowly gaining ground, and a number of biologists are gradually realizing that, in common with all other types of object, animals and plants must be classified in different ways for different purposes. Against the background of this view, morphological, phylogenetic and 'biosystematic' classifications will be seen as systems existing in their own right, for their own particular purposes, rather than as stages towards the final goal of an all-embracing taxonomy of living things. It is to be hoped that, in future editions, Prof. Lawrence will carry his analysis one stage deeper and discuss more fully this borderland region between philosophy and biology.

In the second part of the book a clear and thorough account is given of all the important families of flowering plants and ferns, and, in addition, many other families are mentioned, under their orders, without description. The choice of the sequence of Engler and Diels, because "it is the only available system that has been devised to account in detail for the flora of the world", is a convenient and sensible one. Perhaps the most valuable feature under each order and family is the summary of the phyletic treatment given to it by various authors in the past—information not easily available elsewhere. The text figures illustrating each family add greatly to the usefulness of the descriptions.

Prof. Lawrence has produced one of the most important books for many years in the field of systematic botany, and it is to be hoped that, despite its inevitably high price, it will be widely bought and used by students. J. S. L. GILMOUR

# X-RAY CRYSTALLOGRAPHY IN TECHNOLOGY

### X-Ray Crystallographic Technology

By André Guinier. English translation by T. L. Tippell; edited by Prof. Kathleen Lonsdale. Pp. xiii+330+16 plates. (London: Hilger and Watts, Ltd., 1952.) 56*s*. net.

THIS book was originally published in 1945 and was a good survey of X-ray crystallography as it was at that time. Since then, many developments have occurred which the author has not dealt with; however, the methods have not altered much, and the book forms a good introduction for the university student and research worker.

There are five parts and twelve chapters. The first three chapters are devoted to a study of the general properties of X-rays, the means of producing X-rays, and the theory of crystallography and X-ray diffraction. Chapters 4–6 are devoted to powder photographs, single-crystal photographs and the special applications of strictly monochromatic radiation. Chapters 7–9 deal with the determination of texture, chemical identification by measurement of cell dimensions, the study of phase diagrams and of elastic strains by accurate measurements of cell dimensions and, lastly, the study of order – disorder states in metals. The closing chapters, 10–12, deal with crystal imperfections, the diffraction of X-rays by amorphous substances, and the determination of the size of submicroscopic particles by low-angle scattering. The first appendix contains fundamental theory of X-ray diffraction too difficult to incorporate in the body of the text, and the succeeding appendixes give material such as tables of data about elements and the relation between θ-angles and the spacing for various wave-lengths which can also be found in the standard reference works. A number of plates are provided to illustrate various types of photographs referred to in the preceding chapters.

The book can be recommended as an introduction to the subject, although it is doubtful whether it will satisfy the needs of the technician, to whom the author specifically addresses the book. The omissions of subject-matter which might be expected in a modern book are no doubt partly due to the original time of its production, just after the Second World War, when there was much isolation of the scientific workers in France from those in Britain and other countries. It is almost certain that X-ray crystallographers need to know much more about high-temperature powder cameras, about moving-film cameras of various types, and more about spectrometers and Geiger counters than is here included. The actual description of instruments is, with only one or two exceptions, confined to the principles on which they are constructed. The technician usually requires to know the merits and demerits of various types, and even how to modify a given type to suit his particular purpose. The treatment given here is too brief and too academic really to serve the technician, though it will be useful to students in general.

There is one innovation which seems unfortunate to me—namely, the introduction of the term 'crystal base' to signify the nature and arrangement of the contents of a unit cell of the crystal. In the German literature '*basis*' is firmly established as the correct word; but in English writing 'basis' has only occasionally been used and usually the word 'structure' serves. A possible objection to the use of the word 'structure' is that it also signifies the nature and arrangement of the atoms in the whole crystal, though this ambiguity is not usually a serious difficulty. There are, however, weighty objections to the use of the word 'base'. It has the ordinary meaning of 'lower surface', and if the term 'base' is introduced, as in this book, it will be necessary, for example, to make a confusing statement such as "the base of sodium chloride contains four sodium and four chlorine atoms". Further, the plane (001) is invariably referred to as the 'basal plane', and hence the 'base' in morphology means this plane. If the term 'crystal structure' is not adequate, perhaps 'unit-structure', 'cell-structure' or 'cell-assembly' might be used.

The production of the text, tables and photographs is excellent, and there appear to be few misprints.

# PSYCHOPATHOLOGY OF GENIUS

### The Infirmities of Genius

By Dr. W. R. Bett. (Medical Viewpoint Series.) Pp. 182+6 plates. (London: Christopher Johnson (Publishers), Ltd., 1952.) 18*s*. net.

IN this book, parts of which have already appeared in *Clinical Excerpts*, Dr. W. R. Bett sets out to describe briefly the lives of fifteen men of genius and to relate their mental activity to the various afflictions which beset them. Beginning with Carlyle, whose neurasthenia he attributes to dyspepsia, he proceeds to discuss, among others, Shelley, Whitman, Swinburne, Baudelaire, Burns, Byron, Pope and Lafcadio Hearn. In every case he shows that there can be little doubt that the maladies from which his subjects suffered influenced their literary output and their relation to the society in which they lived. This is what would be expected, and Dr. Bett's treatment of his cases is too slight to enable the reader to consider the much more difficult problem of the precise relation that genius itself bears to the medical history of each individual.

There is no doubt that the literary output of such persons as Byron, Pope or Baudelaire was highly coloured by their infirmities; but these misfortunes were merely those which affect many others and which are clearly not related to genius itself. What is more probable is that the man of genius is likely to suffer from psychosomatic complaints which arise from the very fact of his genius setting him somewhat apart from his fellows; and, indeed, the examples chosen by Dr. Bett would seem to some to suggest this, although the cruder physical deformities naturally played their part in moulding the general attitude of those suffering from them.

What has to be distinguished is genius itself (whatever this may be) and the results of that genius as seen in literary and artistic production. How far such production proceeds purely from the conscious mind or is related to subliminal processes engendered by alcohol or drugs, as seems to have been the case with De Quincey and Coleridge, we do not know. It seems clear from Dr. Bett's intriguing study that, in the cases he cites, genius, although at times hampered and restrained, was able to surmount infirmity and add much without which the world would be considerably the poorer.

E. J. DINGWALL

## A Manual on the Weeds of the Major Crops of Ceylon

Prepared by a Committee consisting of Dr. J. C. Haigh and representatives of the Tea, Rubber and Coconut Research Institutes. (Department of Agriculture, Ceylon: Peradeniya Manual No. 7.) Pp. iii+50+vi+50 plates. (Colombo: Ceylon Government Press, 1951.) 5 rupees.

THIS work is perhaps better described as an annotated atlas rather than a manual, since its chief feature is the set of coloured plates of fifty of the commonest weeds of Ceylon, which admirably portray their habits and also exhibit some details of the reproductive organs. The accompanying text is comparatively brief and provides botanical and native names with short notes on habit, habitats, flowering time and flower colour, modes of propagation, a few descriptive details and mention of uses and means of control. The whole atlas is contained in a loose-leaf cover so that, as the promised supplements appear, the plates can be rearranged in alphabetical order.

It is interesting to note, in this half-century of common weeds, how few would appear to be regarded as definite pests, and many appear to provide useful vegetation-cover for the soil. One notes that the eradication of two species of *Oxalis* is described as impracticable. The perennial grass, *Imperata cylindrica*, evidently plays the part of a tropical couch grass, while the recently introduced annual grass, *Cenchrus echinatus*, has spread to an extent that is causing concern. A dwarf vegetatively propagated variety of the mugwort, *Artemisia vulgaris*, appears to be a greater nuisance than the taller type, which is propagated mainly by seed.

One can look forward to the supplements that are to appear in due course, and the whole should make a valuable addition to the bibliography of the weed flora of Ceylon. E. J. SALISBURY

## The Subject Index to Periodicals, 1951

Issued by the Library Association. Pp. xi+313. (London: Library Association, 1952.) £5 5s. 0d.

THIS index maintains the high standard of production characterizing the earlier volumes and, although now limited to publications in English which are issued in the British Commonwealth, provides the general reader with a key to the contents of many periodicals which are not indexed elsewhere. United States and Canadian periodicals are excluded only because they are adequately covered by the indexes of the H. W. Wilson Co. Highly specialized periodicals in the fields of science and technology are also omitted, because they are mostly indexed or abstracted by the societies and institutions concerned; but the scientific worker and technologist will nevertheless find this index a very useful key to general discussions, in the responsible monthly reviews as well as in scientific and technical periodicals, of such questions as technological education, industrial research, broadcasting, science and society, and the like. The 'proceedings' and 'transactions' of many local societies concerned with archæology, natural history, etc., are covered. The compilation is done on the plan of the 'dictionary catalogue', all entries being arranged under black-letter headings in a single alphabetical order. While cross-references are freely used to link up related subjects and direct attention to unusual, out-of-the-way topics which would otherwise be overlooked, one weakness has been noticed in the referencing from the general to the particular: the referencing under particular countries has made it rather difficult to determine the extent to which this index covers the more general current discussion of Colonial development and welfare or economic assistance of backward areas, whether under United States Point Four Aid or otherwise.

## Sound Recording and Reproduction

By J. W. Godfrey and S. W. Amos. (BBC Engineering Training Manuals.) (Published for *Wireless World.*) Pp. 271+10 plates. (London: Iliffe and Sons, Ltd., 1952.) 30*s.* net.

ALTHOUGH this book has been written primarily as an instruction manual for the use of the engineering staff of the British Broadcasting Corporation, it cannot fail to be of interest to all who are engaged in the techniques of sound recording and reproduction. The equipment described is, quite naturally, mainly that used by the B.B.C., but the principles dealt with concern not only engineers but also those students who are interested chiefly in the academic side of this subject of ever-growing importance.

The first chapter deals with the general principles involved in recording and reproduction, and thereafter the book follows a logical order, dealing comprehensively, though of course not exhaustively, with disk recording, magnetic recording and reproduction and, finally, recording on film. For those requiring data for reference purposes, there are a number of useful appendixes, and to help those who need still further information, a list of references is given.

Throughout the book the text is assisted by many excellent photographs, diagrams and graphs, and altogether the book makes very good reading. As the B.B.C. is now one of the largest users of recorded material in the world and has developed equipment of a very high standard, it does seem that such a book as this is really necessary, and it should receive a hearty welcome, especially by the staff in training.

## An English Course

For Royal Society of Arts and Technical Students. By Stanley Day and S. H. Wiltshire. Pp. 164. (London: Macdonald and Co. (Publishers), Ltd., 1952.) 7*s.* 6*d.* net.

THIS is an excellent little book. It covers more ground than does Sir Ernest Gower's "Plain Words", it is more systematic and it does not fall into the pits about which it warns others. It is succinct but not scrappy, logically developed with interesting and adequate exercises, and delicately spiced with a gentle humour. The book would do a good work in fields besides those of English courses for Royal Society of Arts and technical students for which it is primarily intended. It would solve many of the problems of expression which are met by science workers who have to convey their meanings by using the English language.

Many science students who need a little French and German would derive much benefit by taking this course in their mother tongue as an aid to their studies in other languages. A simple, direct English style which avoids ambiguity and circumlocution is the key to good science-writing, and this is the aim of the authors. An appendix gives a very useful list of books, including drama, novels, and poetry for the extended reading of the student. There is a good section on précis-writing. W. L. SUMNER

# PRODUCTION AND USES OF RADIOISOTOPES*

By Dr. HENRY SELIGMAN
Atomic Energy Research Establishment, Harwell

BEFORE the War one could make materials artificially radioactive by bombardment in big machines like cyclotrons, or by using relatively weak neutron sources. In the cyclotron, one can generally only use one target at a time and the irradiation is therefore costly. The weak neutron sources induce only weak activities. Therefore only a few research workers profited from the radioisotopes which one could produce in these ways.

The situation changed suddenly with the discovery of fission of uranium in 1939. This discovery showed that chain reactions were possible in which more neutrons are created than used. Accelerated by war research, the first chain-reacting atomic pile was working on December 2, 1942, in Chicago. Since 1947 we have had a pile working in Great Britain, and since early 1949 we have had a bigger reactor, BEPO, in full operation.

Such a conventional atomic reactor consists of fissionable material, like uranium metal, and a moderator like, for example, graphite or heavy water. The British piles use graphite as moderator. With the construction of such piles most formidable sources of neutrons were made available, which can be used for the bombardment of nuclei in order to make them radioactive. The great advantage is that in such a reactor a large quantity of material can be made radioactive at the same time. Since 1949, radioactive isotopes, of great specific activity, have been readily available in Great Britain.

New radioisotopes were quickly discovered and the chart of radioactive isotopes started to expand. To-day, there are more than six hundred radioactive isotopes, of which, however, only some hundred can be made conveniently in an atomic pile. For most elements there is at least one usable radioactive isotope. The only notable exceptions are the two elements nitrogen and oxygen for which no convenient radioactive isotope exists.

The process of irradiation is extremely simple. The material to be irradiated is put in a container and then inserted into the pile. After a certain time it is retracted, and either chemically processed or sent direct to the user.

There are a few points which are of importance. The neutron flux varies in the pile from place to place, and has to be carefully measured if one wants to get the right activity for each sample. The second important factor is that one has to observe the self-shielding of highly absorbing materials like gold or cobalt. The specific activity is a function of nuclear data, such as half-life, excitation cross-section for neutrons as well as irradiation time and neutron flux. The neutron flux in the isotope production pile at Harwell is greater than $10^{12}$ neutrons/cm.$^2$/sec.; but even this very high flux is, in some cases, not enough to produce a high specific activity for the purposes for which the isotopes are wanted in industry, research or medicine, and in some cases special preparations have to be made in order to eliminate the non-radioactive isotopes. This is usually done by a chemical process, when the isotope produced is chemically different from the other atoms. One such process is the $n,\gamma$-reaction followed by a $\beta$-decay, of which the production of iodine-131 from irradiated tellurium is a good example. A number of neutron–proton reactions occur easily in the pile, and the production of carbon-14 from nitrogen-14 and phosphorus-32 from sulphur-32 are the most important of these applied reactions. Tritium is extracted from irradiated lithium after an $n, \alpha$-reaction. Fission products can be separated either on ion-exchange columns or by co-precipitation methods. Szilard–Chalmers reactions are used, especially in the preparation of carrier-free radioiron, for which potassium ferrocyanide is irradiated. In all these cases extensive radiochemical preparations have to be made and sometimes the extraction procedures involve only between $10^{-9}$ and $10^{-12}$ gm. of material. Quite a number of syntheses, mainly of organic compounds, have been made by the Radiochemical Centre at Amersham, which is an out-station of Harwell.

Radioisotopes are useful for three reasons. The first is the very great sensitivity in detecting the smallest amounts of active material. If we compare the sensitivity with orthodox methods, for example, spectroscopy, we find that in many cases, if not all, it is much better. The limits of detection in spectroscopy are usually between $10^{-7}$ and $10^{-8}$ gm. Some of the carrier-free radioisotopes can be detected up to $10^{-14}$ gm.; but even if the material is not carrier-free, a sensitivity of $10^{-10}$ and $10^{-12}$ gm. is quite usual, and shows that isotopes are superior to orthodox methods of analysis by anything between a thousand and a thousand million times. Therefore, rightly, the application of these new tools to science has been compared with the discovery of the microscope. Another similarity with the microscope lies in the fact that it is possible to locate these small traces without damaging the material, whereas with chemical methods, when testing trace amounts, the material is either destroyed or dislocated. It is this possibility of locating the trace elements which is so important in research and industry. The third big class of applications is the use of the beta- and gamma-radiations emitted from radioisotopes. They are used for ionizing air in order to make it conductive for electricity, for penetrating materials for the purpose of making radiographs or for destroying tissue or blood corpuscles.

Industry has made use of the sensitivity of the method in tracing underground currents of water. For this purpose one can use tritiated water; although the beta-radiation from tritium is rather weak, with modern methods of detection very small traces of this material can be measured. The advantage of using tritiated water is that there is no danger of ion adsorption on soil that would occur with most other ions. In the oil industry, it is frequently necessary to mark the interphase between two oils pumped through the same pipe-line. Indeed, it is becoming a routine method of detection to add a radioactive isotope to indicate when a different oil is coming through a pipe-line at a distant location.

Leaks in water mains and pressurized cables have been detected successfully by adding small amounts of radioactive materials to either the water or the gas in the pressurized cables. In France, a method has been developed for using methyl bromide in which the bromine is radioactive. This is injected into the gas of the pressurized cables ; if it leaks out into the ground, the methyl bromide remains in the soil and can therefore be easily detected hours later by monitoring on the surface with simple detection instruments. All these applications of radioisotopes enable us to carry out operations which would be very difficult to do by any other method.

---

* Substance of a Friday Evening Discourse at the Royal Institution on February 6.

We are frequently called upon to make ventilation experiments in factories or assembly rooms. Here we use radioactive vapours or gases. Ethylenedibromide has been used successfully, but will eventually be replaced by noble gases like krypton-85 or xenon-133, when they become available in the near future. Great care has to be taken that these gases are not adsorbed on walls or machines, and therefore noble gases are more suitable than radioactive vapours.

Isotopes can also be used in problems of mixing. The problem may be to find when the mixing process is complete between small amounts of material like vitamins and large amounts of other foodstuffs. By adding a small amount of harmless short-lived radioisotope, the mixing can be controlled and checked when the material is transferred to the conveyor belt.

A thickness gauge has been developed which works by attenuation of radiation by the material. Another system of measuring the thickness of the coating of materials makes use of the reflexion of beta-rays. The reflexion depends on the atomic number and the thickness of the reflecting material, and can be used to measure the thickness of one material on another, where the two materials have different atomic numbers.

The discharge of electrostatic electricity produced during a manufacturing process which entails rolling insulating material like plastic, rubber, paper, etc., is often a great problem to industry. Dust particles are, for example, attracted to the fabrics in weaving nylon or rayon when they are left in the looms overnight. In some cases one can neutralize the static charges by ionizing the air with a radioactive source giving beta-radiation such as thallium-204.

The ionization from radioisotopes can also be used to help in starting gas discharges. A gas discharge can only start if a free electron is present. The presence of beta-emitting isotopes makes the starting operations more reliable and is being used to promote ignition at spark gaps and to make cold cathode ray tubes work more smoothly.

In process control, radioisotopes have been used successfully in the operation of ion-exchange columns. Thus, radioactive sodium ions are kept back by a resin and the radiosodium can afterwards be dissolved out under controlled conditions. This method is used in the separation of zirconium and hafnium by adding a small amount of radiozirconium and radiohafnium, which are retained in the column. One can find out when the column is saturated by measuring the activity at the bottom of the column ; the washing-out agent for one material is then added, and when this one is totally dissolved, which again is checked by activity measurements, the second washing-out agent is added. It is a remarkably easy way of ensuring a constant accurate analytical control.

An important use of radioactive sources is for gamma-radiography. Isotopes have a number of advantages over X-ray equipment. They are less cumbersome. A 2- or 4-mm. cylinder can be used for insertion into a small pipe, for example, or for taking radiographs under water. By this means welds, for example, in the shipbuilding industry can be tested. Radiographs can be made in the field, as no electrical supplies are necessary, and lastly, these gamma-sources need no maintenance. The main disadvantage is that the exposure-times necessary at present are relatively long ; but this disadvantage will become less and less serious as sources of higher specific activities become available. Three isotopes are available for gamma-radiography, depending on the purpose needed. Cobalt-60 emits on average 1·2-MeV. gamma-rays, which can be used for making radiographs of 2–6 in. of steel ; iridium-192 emits gamma-rays of 0·6 MeV. and can be used for investigating thicknesses of steel $\frac{1}{4}$–2 in. ; and thallium-170 with 80-KeV. gamma-radiation can be used for radiography of light alloys. Industry in all countries is already making extensive use of these sources.

Much use has been made of isotopes in metallurgy for measurements of self-diffusion, especially by following the movements of molecules under heat treatment. The measurement of wear of metals becomes easy by making one part of the metal radioactive. Thus, the wear of piston rings in an engine can be determined by making them radioactive and measuring the activity on the cylinder walls and in the lubricating oil.

In physical chemistry, labelled catalysts have been used to demonstrate their part in chemical reactions, and small vapour pressures of different materials have also been measured. The passage of water through membranes or 'Cellophane' has been accurately determined by using tritiated water.

Activation analysis is being used, especially in cases where the normal methods of chemistry fail. A special advantage is the localization of trace amounts. In France, use was recently made of activation analysis in establishing evidence in a murder case. A man had been poisoned with arsenic ; but difficulty arose in finding out when arsenic was first administered to him. Arsenic accumulates very quickly in the hair after administration, and, having a high activation cross-section, becomes very radioactive by pile irradiation, whereas the normal components of hair are scarcely affected. Therefore, by irradiating a hair of the poisoned victim in the French pile and making an autoradiograph of the hair afterwards, the time could be established when the arsenic was administered, since the rate of growth of hair is known. Industry is making use of activation analysis in, for example, the determination of impurities of arsenic in germanium for the electrical industry, where one can determine 0·01 parts per million. Traces of copper have been accurately measured in the manufacture of rubber, where copper has a very adverse effect.

The uptake of phosphorus in plants has been determined by using radioactive phosphorus. Such experiments were made in order to find the best fertilizing conditions, and, in fact, it is the only method of distinguishing between the phosphorus taken by plants out of the ground and that given as fertilizer. It is claimed that this investigation has made possible considerable savings by demonstrating the optimum fertilizing conditions.

In zoology, radioisotopes have been used as tracers to follow animals underground.

Great progress has been made in biochemistry. Quite a number of metabolism studies have been made which would be difficult, if not impossible, without the help of isotopes. The protein and plasma protein metabolism have been investigated, using carbon-14 amino-acids. Penicillin has been made active and its reaction has been followed in animals.

The future will see an expansion of the use of radioactive materials as bigger sources are used for irradiation purposes. At the moment work is in hand in examining chemical synthesis or changes happening under very strong radiations. At the same time, some progress has been made in trying to sterilize foods and penicillin by radiation. The dosages necessary for this are very big indeed. They are of the order of a hundred thousand or millions of roentgens, and in Great Britain it will be another year or two before facilities are available for this kind of research.

The Atomic Energy Research Establishment at Harwell and the Radiochemical Centre at Amersham are sending out more than nine thousand shipments of radioactive materials a year to some thirty-seven countries, including the United States, most South American countries, Africa, India, Australia and New Zealand. The majority are used in medical research, diagnosis and therapy.

In medical diagnosis very small amounts of activity are required and have been used successfully for blood circulation tests. Work is in hand in tracing tumours of the brain by tracer methods. In therapy, the greatest use is that made of radioiodine in the treatment of thyroid toxicosis. Some cases of thyroid cancer can be treated successfully with radioiodine. Cancer of the bladder can be treated with an active bromine solution in a rubber balloon. Colloidal gold is used as a palliative treatment of malignant pleural and peritoneal effusions. Radiosodium is used in plastic surgery. Radiophosphorus is used in polycythæmia vera. Big telecurie sources are used for general irradiation, and special beta-sources which only penetrate a few millimetres of skin are used in the treatment of some surface cancers. These are usually applied as radiophosphorus built into a plastic. The plastic is irradiated in the pile and, after irradiation, the radiotherapist cuts out the right shape of the plastic which he needs and applies it to the malignant tissue, leaving it a calculated time in order to give the exact radiation dosage.

In the early post-war days, people were apt to speak of isotopes as 'by-products' of atomic piles. This picture has changed now. Radioisotopes have helped industry in solving many problems, they have widened the field of research in many sciences and have helped the medical man to treat disease and, in some cases, to save life. They have become an important part of the atomic energy development, and I am convinced that we are only at the beginning of the development of 'isotopics'.

# THE NATURE CONSERVANCY

SOME aspects of the work of the Nature Conservancy were the subject of discussion at a meeting of the Linnean Society on February 19. In his opening remarks, Captain C. Diver said that conservation and research, the Conservancy's two main functions, are necessarily very closely linked. He and Dr. Conway dealt with two ways by which scientifically valuable places might be safeguarded for study; Mr. Skellam and Dr. Ovington, who are each in charge of one of the half-dozen main research programmes now being carried out by the Conservancy, then outlined one or two of the problems on which they have been working.

The most effective means of conserving any special place is to acquire it or otherwise arrange for it to be managed as a Nature reserve. This is not always easy because of land requirements for forestry, agriculture, service training, and development of one kind or another. To exemplify these conflicting demands, twelve cases were mentioned where places of the highest scientific value have been lost or threatened; these included the requirement of Bilston Glen for dumping colliery spoil and the Arne heaths in Dorset for ball-clay working.

The Conservancy has, however, already declared nine reserves (two in Scotland and seven in England) totalling about 22,000 acres; and negotiations are proceeding satisfactorily in respect of at least seventeen more. Informal agreements have also been made with the owners of several other properties; and help is being given with the management of a few sites already held as reserves by other bodies. Two local authorities are using their new powers to establish local reserves.

The Conservancy has also acquired two properties —one in the Lake District and one in Dorset—which are being equipped as research stations; and field research facilities are being provided at Moor House Reserve (Westmorland) and at Beinn Eighe Reserve (Wester Ross).

Dr. V. M. Conway said that the making of Nature reserves can safeguard only a small fraction of the wild country that must be kept in something like its present state if reasonable stocks of the native flora and fauna are to be preserved. Power to conserve other interesting places rests largely with local authorities; but under Section 23 of the National Parks and Access to the Countryside Act, 1949, the Conservancy has the duty of notifying planning authorities about the areas which are of special scientific interest by reason of their flora and fauna, or geological or physiographical features. Local planning authorities are required to consult the Conservancy before giving planning permission for developments likely to affect areas so notified. The Conservancy can then put the scientific case for conservation, and can approach owners and other interested parties. One of the weaknesses of this arrangement is that changes in sylvicultural or agricultural methods do not constitute 'development' and might, therefore, occur without the Conservancy's knowledge, often to the detriment of the valuable characteristics of the area.

The choice of areas for notification under Section 23 rests primarily on the recommendations of the local committees of the Nature Reserves Investigation Committee which was at work during the War. These recommendations have been checked and revised since the Conservancy came into being in 1949—work which has been made possible only by a large amount of voluntary help. Notifications must be made with minimum delay because so many good places are being lost all the time, and planning authorities need information as quickly as possible. For this reason there are many gaps and inequalities in the existing lists; but by careful collection of information over the next four or five years it is hoped that these may be largely removed in time for the first revision of county development plans.

Passing from administration to research, Mr. J. G. Skellam said that the statistical analysis of observational data enters into all aspects of the Conservancy's scientific work. In order to illustrate the mathematical approach, he selected just one topic, that of quadrat sampling. This subject is of considerable importance to the Conservancy because of the need to assess floristic and faunistic changes which may be taking place in the same locality with the passage of time and to measure the differences which exist from place to place; and in both cases to do so with known accuracy.

Mathematics can be applied to biological problems in two ways. In the first place, mathematical functions can be used for describing numerical results in a concise way. But such descriptions are often arbitrary and only acquire meaning when they can be related to the underlying causes. It is instructive in this connexion to construct simple models or idealized versions of the biological situation as suggested by observation and experiment and to deduce their consequences. In this way we not only discover functions which are suitable for description of numerical data, but we also construct standards which play the part of a basis for comparison against which the real complexities may be critically demonstrated.

Dr. J. D. Ovington then briefly described some of the woodland research carried out by the Conservancy over the past three years in co-operation with the Forestry Commission. Investigations are progressing at several widely different localities in Great Britain. Each locality contains a number of woodland plots of different tree species established on what were originally fairly uniform sites. The principal characteristics of the various woodlands and their dynamic relationships are being considered with particular reference to the climate, soil and ground flora. Tree canopies intercept precipitation and in so doing diminish and redistribute the rainfall reaching the soil. The irregular distribution of the precipitation pattern in woodlands can in part be attributed to the raindrops coalescing on the canopy and falling as large drops. Once established, the trees influence soil formation, and, after twenty years of afforestation, marked differences, particularly in the accumulation of surface organic material, soil *p*H and nutrient content, develop under different tree stands. The weight of the ground flora present in a woodland may be related to the age and closeness of the trees and to the type of woodland that has been established. The associated woodland floras differ considerably in their floristic composition and give some indication of the extent to which site conditions have been modified by the various woodland plantations.

Discussing Dr. Ovington's paper, Dr. J. Ramsbottom directed attention to the importance and specificity of the fungal flora in different types of woodland—facts which are frequently overlooked. Dr. Ovington confirmed that the species of fungi present in the plots he has worked on show differences like those described by Dr. Ramsbottom, and he thinks it is of primary importance to understand the part played by these species in the nutrient cycles. Replying to Mr. W. T. Stearn, he explained the technique used for measuring the size and dispersal of raindrops.

Speaking of the Midlands, Dr. A. Tindell Hopwood said some useful work might be done on the covering of slag-heaps with vegetation. Dr. Conway replied that one of the research students supported by the Conservancy is already working on this problem and that the Conservancy might take a direct interest in it when it has made sufficient headway with its primary task of conserving unspoilt areas of land. Prof. C. T. Ingold expressed the hope that the Conservancy will not get too departmentalized and will keep in close touch with local natural history societies and possibly issue a journal. Captain Diver said that he expected regular reports will now be issued. Mr. Stearn pointed out that many places are not in a static condition but are changing all the time, and asked what will be done about this. Captain Diver replied that when places are considered for reservation it is essential to know whether one wants to maintain them in a particular phase, for example, downland turf, or to study the natural sequence of change as in a prograding coast; and reserve management policy has to be directed to achieve the required result.

# ELECTRICAL DEVICES FOR CONTROLLING THE MOVEMENTS OF ANADROMOUS FISH

INCREASING attention has been paid, over the past few years, to the use of electric currents as aids for catching fish in freshwaters, and it is evident that the use of electrical methods promises to become an important technique both for the fisheries biologist who wants to carry out census work and the owner who wants to reduce or eliminate populations of unwanted fish from his waters.

A recent communication[1] by a member of the staff of the North of Scotland Hydro-Electric Board has described other uses of electric currents in fisheries. Hydro-electric works are bound to have important effects on the movements of migratory fish, since they frequently interpose barriers to migration or create other unnatural hazards in the course of their operation. Over much of the area covered by the North of Scotland Hydro-Electric Board, salmon are the most important migratory fish, and it has been found necessary to try to discover ways in which the potentially deleterious effects of hydro-electric developments could be minimized. When constructing impounding dams, the Hydro-Electric Board is legally bound to provide fish ladders so that migrating fish can pass upstream or downstream; but the construction of hydro-electric power stations creates other problems. Downstream migrants may be drawn into the tunnels or aqueducts which lead to the turbines, and the volume and turbulence of the water discharged in the tailrace from the stations may deflect migrants from their course and so interfere with their passage upstream. In the communication mentioned, an account was given of devices which are being used for trying to solve both these problems, following experimental work in the Board's laboratory at Dundee.

At Morar, an electric screen has been erected to deter salmon and sea trout from entering the tailrace of the power station. This screen consists of a row of aluminium electrodes, each about 14 ft. in length, which extends to three inches from the bottom of the channel, together with two electrodes, about 16 ft. apart, placed 7 ft. downstream from the main screen. A pulsating electric supply is applied across the electrodes. Salmon are seen to react when about 5–6 ft. from the outer electrodes since, at this distance, they turn and swim upstream past the end of the

Experimental screens at the Power Station, Pitlochry (Perthshire)

tailrace. Reactions are seen in sea trout when they are about 2–4 ft. (depending on their size) from the inner row of electrodes. Experimental work with this screen was first carried out in 1950, was repeated in 1951 and again repeated, with improved electrical equipment, during the spring of 1952. During the last period, constant observation was maintained on the movements of fish. No fish were seen to penetrate far into the tailrace, and all the fish seemed to behave normally after leaving the electrified zone; no signs of distress were seen and there was no inclination to remain inactive.

The success of this screen at Morar has led to the installation of similar screens at other sites. The accompanying photograph shows a screen which has recently been set up on the tailrace from the power station at Pitlochry, which is situated at the lower end of Loch Faskally.

Experiments on the use of electric screens to divert descending salmon smolts have been carried out, over the past three years, at Dunalastair Dam on the River Tummel in Perthshire. Here the screen consists of two parallel rows of aluminium tubes strung diagonally across the lower end of Dunalastair Reservoir immediately above the dam. The downstream row is made up of 272 tubes one foot apart, and the upstream row, which lies 6 ft. from the downstream row, consists of 34 groups of tubes spaced at 8-ft. intervals. As at Morar, a pulsed current is applied across the screen. The purpose of this screen is to divert the downstream-migrating smolts from the entrance to the aqueduct, which conveys water from the reservoir to the power station at Tummel Bridge, into the fish pass. Though this device has not been so successful as the tailrace screen at Morar, it has shown sufficient promise to warrant a continuation of this experiment.

As well as carrying out tests on the use of electric screens, the North of Scotland Hydro-Electric Board has also devised an automatic electrical counter which has been installed in the fish ladders at Clunie and Pitlochry Dams. Its operation depends upon the difference in resistance to electrical currents between a salmon or sea trout and the water in which it is swimming; the passage of a fish through the submerged pipe linking two chambers of the fish pass can thus influence an electrical bridge, and this disturbance can be made to work a counter. The apparatus can be adjusted so that only fish greater than a certain size are counted, and refinements make it possible to operate this equipment in waters of widely varying chemical content. The passage of salmon upstream and the passage of kelts downstream are recorded separately; but if a fish does not complete its journey through the pipe, its passage is not recorded. Branches of trees, logs of wood, empty tins and other debris passing down the fish pass do not affect the counter. This equipment was in operation at Pitlochry during 1952, and daily checks have shown the electrical counter to have an accuracy approaching 100 per cent.

The future development of all these devices will be followed with great interest by all who are concerned, professionally or privately, with the welfare of salmon fisheries. The importance of the electric fish screens needs no emphasis, and the counter, though it plays no part in controlling the movements of migratory fish, should produce records the value of which will increase as the years pass. It is to be hoped that the fullest possible records will also be kept of environmental conditions, since in these circumstances the records from the electric counter could prove valuable additions to what is known of the characteristics of the upstream migration of salmon.

---

# OBITUARIES

## Prof. G. D. Hale Carpenter, M.B.E.

**Geoffrey Douglas Hale Carpenter**, professor emeritus of zoology (entomology) in the University of Oxford, died at the Radcliffe Infirmary on January 30 at the age of seventy. He came of a distinguished academic family and was a grandson of William Benjamin Carpenter, F.R.S., one of the most eminent physiologists of his time. His father was an assistant master at Eton, and his mother the daughter of another; but although born in the College itself his early education was received at the Dragon School and Bradfield. He then passed to St. Catherine's, Oxford, where he took his B.A. in 1904, obtaining second-class honours. Throughout this period he took a wide interest in natural history, and especially ornithology, conchology and entomology, so laying firm foundations for his future career. His first paper was an unpublished one on the mother-of-pearl moth (*Sylepta ruralis* Scop.) and its parasites which he read, while still an undergraduate, to the Ashmolean Natural History Society of Oxfordshire, one of the many societies of which he later became president, and which he always regarded with much affection. From Oxford he passed with a University Entrance Scholarship to St. George's Hospital, London, qualifying M.R.C.S., L.R.C.P., taking the degrees of B.M. and B.Ch. in 1908, and eventually holding the appointments of house-surgeon and house-physician.

Hale Carpenter's interest in entomology led him to specialize in insect-borne diseases, and in 1910 he entered the Colonial Medical Service. The following year found him in the Sesse Islands in the north-west part of Victoria Nyanza, where he had been sent to study the bionomics of the tsetse fly, *Glossina palpalis*, which had recently appeared in Uganda and within a few years had caused more than two hundred thousand deaths from sleeping sickness. The results of his researches were published in the Reports of the Sleeping Sickness Commission of the Royal Society (1912, 1913 and 1919) and were presented as a dissertation for his D.M. degree at Oxford.

In the First World War, Hale Carpenter served as a captain in the Uganda Medical Service, his duties taking him into many interesting parts of Africa that he would otherwise never have visited and providing him with rich material for his book "A Naturalist in East Africa" (1925) and for many scientific papers on insect bionomics, polymorphism and mimicry. For his war services he received the M.B.E. On demobilization he resumed his work on tsetse fly, becoming specialist officer for the control of sleeping sickness in Uganda. He retired from the Colonial Medical Service in 1930; but at the request of the Secretary of State for the Colonies undertook a special investigation into tsetse fly in Ngamiland during 1930–31.

While in Africa, Hale Carpenter kept up a voluminous correspondence about his observations on insects with Sir Edward Poulton, Hope professor at Oxford, and on returning to England he built a house on Cumnor Hill, just outside that city. For a year or two he visited the Hope Department of Entomology, Oxford University Museum, daily, studying the vast stores of African insects, many of which he had collected himself, and helping Sir Edward Poulton. When Sir Edward retired in 1933, Hale Carpenter succeeded him, occupying the chair for the next fifteen years, and so qualifying for the title of emeritus professor on his retirement in 1948. During this period he continued his studies on mimicry and geographical distribution, and paid special attention to the vexed question of the attacks of birds on butterflies and its significance for evolutionary theory. At the same time he was deeply concerned about the future of his Department, and not only did all he could to enhance its value, but also appealed to the University for a new building and an increased staff.

During the Second World War, Hale Carpenter lectured on camouflage and tropical medicine to troops in training near Oxford, prepared special booklets for the African campaigns and served as head warden of the air-raid precaution service for Cumnor.

He frequently attended and spoke at scientific meetings in London, was president of the Royal Entomological Society during 1945–46, vice-president of the Linnean Society during 1935–36 and was an ardent supporter of the British Association.

His writings included "A Naturalist on Lake Victoria" (1920) and "Mimicry" (1933). His study of the genus *Euplœa*, a genus of butterflies found on many Pacific Islands, was completed shortly before his death and is to appear in the *Transactions of the Zoological Society of London*.

Hale Carpenter was a tall, distinguished-looking man with white hair, easy of address and with a keen sense of humour. His chief recreation was gardening, the varied soils at his home at Cumnor Hill enabling him to grow a wide variety of plants. He was an ardent churchman, secretary of the Parochial Church Council, and chairman of the Cumnor branch of the Oxford Preservation Trust. His holidays were often spent in Cornwall, where he would walk, watch birds and collect insects.

He married in 1919 Amy Frances Thomas-Peter, of Treviles, Cornwall, who survives him.

B. M. Hobby

## Prof. N. A. V. Piercy

In the passing of Prof. N. A. V. Piercy, on February 1, the profession of aeronautical engineering has lost one of its ablest teachers and a pioneer in the teaching of aeronautics.

Norman Augustus Victor Piercy was born in London on August 10, 1891, and after being educated at Hampton Grammar School he was apprenticed to Yarrow and Company, Scotstoun (1908–13). He obtained an honours degree (London) in engineering at East London College (now Queen Mary College) in 1913 and immediately became engaged at Shoreham on the Cedric Lee aeroplane, known as the 'Doughnut', which had a circular ring for its wing plan-form. The period until 1919 found him engaged at East London College in researches on this novel wing, as well as special investigations for the Admiralty. During this time he designed his own 4-ft. wind tunnel, which was built of steel plating obtained from a destroyer. This tunnel is still in use.

In 1919 he was appointed head of the Department of Aeronautics at East London College and started the first university course with aeronautics as a recognized subject. In 1920 he obtained his D.Sc., for his work in connexion with the flow behind aerofoils. His subsequent researches in aerodynamics included flow in pipes, heat flow from moving bodies and aerofoil theory from which the 'Piercy aerfoil' was developed.

As a teacher Piercy inspired his students, and in consequence he soon gathered a small team of research workers around him. In 1934 he was appointed reader in aeronautics in the University of London, and in 1949 his work was officially recognized when the title of University professor of aeronautical engineering at Queen Mary College was conferred upon him.

During the Second World War Piercy was in charge of the Aeronautical Department in the University of Cambridge, in addition to his work at Queen Mary College.

Piercy was the author of "Aerodynamics", which was published in 1937 and revised in 1947, "Elementary Aerodynamics", published in 1944, as well as various papers read before learned societies. At the time of his death he was engaged in a third edition of "Aerodynamics", incorporating more recent advances in supersonic flow. He was a man of amazing energy and served on many committees dealing with the teaching of aeronautics, as well as being a member of the Council of the Royal Aeronautical Society during 1935–39. His other interests included music—he was an able pianist—golf and the collecting of antiques.

H. F. Winny

### Dr. Y. A. Bilibin

Yury Alexandrovich Bilibin was born on May 19, 1901, in Rostov in Yaroslav province, and he died on May 4, 1952, in Moscow. After active participation in the civil war of 1917–21, he graduated in 1926 at the Leningrad Mining Institute. His scientific work is intimately associated with the geological survey of Eastern Siberia, and he became an authority on the mode of occurrence and mode of origin of ores of gold, tin, copper and other metals. He constructed metallogenetic maps and lectured on metallogenetic provinces, and made considerable progress in the application of geochemistry to the problem of ore genesis. He also published important papers on the igneous rocks of the Aldan region in Eastern Siberia and was particularly interested in the origin of alkaline rocks. In 1943 he received his doctorate and was later elected a corresponding member of the Academy of Sciences. In 1948 he came to London to take part in the meeting of the International Geological Congress, and those who met him there will remember him as a shy but very friendly person who was an outstanding geochemist and geologist.

S. I. Tomkeieff

We regret to announce the following deaths:

Mr. Andrew Gray, technical general manager during 1928–32 of Marconi's Wireless Telegraph Co., Ltd., and an early assistant of Marconi, aged eighty.

Prof. J. W. McBain, F.R.S., emeritus professor of chemistry in Stanford University, California, and lately director of the National Chemical Laboratory, India, on March 12, aged seventy.

# NEWS and VIEWS

### Agriculture in the University of Sydney: Prof. W. L. Waterhouse

Prof. W. L. Waterhouse, research professor in the Faculty of Agriculture, University of Sydney, retired at the end of 1952. During his thirty-two years of service, he had occupied the positions of lecturer, reader and professor. Prof. Waterhouse lectured on plant pathology, genetics and plant breeding, and agricultural botany. The scientific discipline derived from these courses was ideal, and has stood many graduates in good stead no matter in what field of scientific endeavour they work; his teaching was inspired. His main researches were in the field of cereal diseases, in which he accepted the challenge of solving the wheat rust problem of Australia. He had many successes, the culmination of his work from a practical point of view resulting in the production of an outstanding variety known as Gabo, which was resistant to all the forms of stem rust existent in Australia up to 1948. But perhaps his greatest contribution was to give a complete understanding of the problem, a thorough knowledge of the rusts, techniques for breeding resistant varieties, and above all hope for the future. Prof. Waterhouse has been a good colleague and has played a considerable part in developing the Faculty of Agriculture in the University of Sydney. Although handicapped by wounds sustained in the First World War when he was awarded the Military Cross, he never spared himself in his teaching and research. Prof. Waterhouse's work has been recognized by many awards: he was given the Farrer Memorial Medal in 1937 and again in 1950; in 1943 he received the Clarke Memorial Medal of the Royal Society of New South Wales, and in 1948 the Australian Medal of Agricultural Science. Now his University has conferred on him the title of emeritus professor. Truly can it be said that here is a man who has devoted himself to science and to agriculture, so that the lot of the farmer and the community might be improved and the world made a better place in which to live.

### Geophysics at the Carnegie Institution of Washington: Dr. P. H. Abelson

Dr. Philip H. Abelson, chairman of the Biophysics Section of the Department of Terrestrial Magnetism in the Carnegie Institution of Washington, has been appointed director of the Geophysical Laboratory of the Institution with effect from September 1 next. Dr. Abelson's research career began under Prof. Ernest O. Lawrence at the University of California, Berkeley, where he made the initial identification of radioactive antimony, tellurium and iodine as products of uranium fission, gaining his Ph.D. in 1939. He then joined the Carnegie Institution as a staff member and took a prominent part in the design and construction of the cyclotron at its Department of Terrestrial Magnetism at Washington, D.C. During the Second World War he was a physicist at the Naval Research Laboratory, where he developed the liquid thermal diffusion method for enrichment of uranium-235, and under his general supervision a plant employing the method was designed and constructed at Oak Ridge for work in connexion with the atomic bomb. Dr. Abelson returned in 1946 to his old Department in the Carnegie Institution and organized a programme of biophysical work for using isotopes and radioactive nuclei in the study of the processes by which living cells select chemicals from their environment and organize them into new cells; as a result, a number of processes in the chemistry of amino-acids have been elucidated. At the same time he has continued his interest in geophysics and geochemistry, and in his new post he is going to a laboratory where during recent years much of the work has been focused on novel experimental techniques for studying the physics and chemistry of the solid state, such as the melting and solubility relations of silicates, especially in the presence of water, and the transport of minerals by solution in a gas phase.

### Dannie Heineman Prize of the Heineman Foundation

The first award of the Dannie Heineman Prize of the Heineman Foundation for Research, Educational, Charitable and Scientific Purposes, Inc., has been made to Prof. Otto Neugebauer, of Brown University, Rhode Island, for his book entitled "The Exact Sciences in Antiquity" (Princeton University Press, 1951, and Oxford University Press). The Prize, which is worth five thousand dollars, will be awarded every three years to the author of an outstanding book on mathematical or physical sciences which opens up important fields of research. Prof. Neugebauer, who is an Austrian by birth, is a mathematician who has turned his knowledge to the study of Egyptology and, in particular, to the deciphering of Babylonian and Sumerian cuneiform texts dealing with mathematical and astronomical subjects. The Heineman Foundation was established by Mr. and Mrs. Dannie N. Heineman, of Charlotte, North Carolina, in order to further educational, charitable, religious and scientific enterprises and projects, without reference to nationality, race, creed or colour. Further information can be obtained from the secretary of the Foundation at Suite 1700, 50 Broadway, New York 4, N.Y.

### Oil Palm Research in Nigeria

The Oil Palm Research Station, Benin, formerly a station of the Nigerian Agricultural Department, has recently been transformed into the West African Institute for Oil Palm Research. This Institute has been set up by statute to serve the British West African territories in all matters relating to research on the oil palm—a tropical crop of great contemporary value and importance. Annual reports on the work of the Institute are promised in due course, these continuing the records of the former Research Station. Meanwhile, quarterly progress reports are being made available to those who are interested in this crop; for the managing committee is anxious to make the work of the Institute as widely known as possible. Leaving aside the numerous matters of administrative detail, inseparable from the establishment of a new organization, the contemporary report (No. 3; October–December 1952) contains items of scientific and practical interest on problems of seed germination, the effect of leaf pruning, the effect of burning and non-burning techniques of land-clearing on subsequent yields—a matter of rather special interest to the tropical planter, the agronomist and the soil chemist—genetical and breeding investigations and progeny trials, and the investigation of various obscure diseases to which the oil palm is subject. Although at several points the work has been restricted and impeded by staffing difficulties, the Institute is now an active going concern. For this, much credit is due to the director, Mr. F. W. Toovey, for a notable administrative and scientific achievement in the face of difficulties that only workers with tropical experience are likely to appreciate to the full.

### Association of Clinical Biochemists

The Association of Clinical Biochemists was formed at a meeting held at the Postgraduate Medical School of London on March 28. Regional societies in the Midlands, Glasgow, the north-west and the south of England have been in existence for some time, and an interim committee of these groups was set up last year under the chairmanship of Prof. E. J. King. The activities of the new Association will be both scientific and professional and will comprise the field, now somewhat incompletely covered, between pathology, clinical medicine and biochemistry. The Association will hold regional and national meetings for reading papers and giving demonstrations, and expects to hold joint discussions with other organizations to deal with selected topics. It hopes to co-operate with other societies affiliated to the International Association of Clinical Biochemists in a scheme for the standardizing and periodical checking of analytical methods used in hospital laboratories. The following papers were read at the inaugural meeting: Mr. E. B. Love, on the laboratory control of anticoagulant therapy; Dr. I. D. P. Wootton, on the quartz spectrophotometer in clinical chemistry; Drs. H. Bickel, J. Gerrard and E. M. Hickmans, on the influence of phenylalanine intake on phenylpyruvic oligophrenia; and Dr. A. L. Latner, on quantitative paper-strip electrophoresis of serum proteins. The meeting accepted a set of rules submitted by the interim committee, which was instructed to nominate a president and to hold elections to a council not later than August 31. Until then the interim committee is to act as a temporary council; Dr. A. L. Tárnoky (Royal Berkshire Hospital, Reading) is secretary of the committee.

### Deep-sea Trawling

The results of the deep-sea trawling which was done by the Swedish Deep-Sea Expedition, 1947–48, are given in the "Reports" of the Expedition (2, Fasc. 1; 1951. Pp. 148+2 plates. Göteborg: Elanders Boktryckeri. 25 kr.). In an introductory paper, Dr. O. Nybelin, who was in charge of the zoological work, discusses the technical difficulties of trawling at depths greater than four thousand metres. For this work the expedition employed a thirty-foot otter trawl, of the type used by Scandinavian fishermen to catch the deep-water prawn, *Pandalus borealis*. In the operation of this trawl, considerable use was made of echo-sounding to avoid trawling over hard, rough bottoms, and also of calculations (by B. Kullenberg) on the shape and length of the cable during deep-sea trawling. Dr. Kullenberg's calculations are also published in the present volume. As a result of this preliminary attention to details of technique, the Swedish deep-sea trawl-hauls were relatively more successful than many of those taken on previous expeditions, and the remaining papers in the publication record the zoological catches, in particular the echinoderms, cœlenterates, bryozoans and polychætes. The starfish collections, described by Jensenius Madsen, strongly support the view that the real deep-sea fauna is essentially cosmopolitan. Thus, three species of starfish found by this expedition in the Atlantic had hitherto been known only from the Pacific or Indian Oceans.

### Mathematical Association: Meeting in Sheffield

The annual general meeting of the Mathematical Association will be held in the University of Sheffield during April 8–11. The business of the Association (election of officers and the Council, etc.) will be dealt with on the morning of April 9, and in the afternoon the president, Mr. K. S. Snell, of Harrow School, will give his address, his subject being "School Mathematics To-day and To-morrow". Other topics which will be considered at the meeting are the craft and science of metallurgy, infinity, the Mathematics Division of the National Physical Laboratory, the transition from the primary to the secondary school, the theory of games, and 'from examination question to industrial problem'. In addition to the usual exhibition of books, it is hoped to arrange an exhibition on teaching-aids in primary and secondary schools and another one on modern calculating machines. All arrangements for the meeting are in the hands of the local secretary, C. R. Barwell, 53 Duke's Drive, Newbold, Chesterfield, from whom further information can be obtained.

## Scientific Film Association

AT the annual general meeting of the Scientific Film Association, the following officers were elected for the year 1953–54: *President*, Sir Arthur Elton; *Vice-President*, W. J. C. Chapple; and *Honorary Treasurer*, K. Baron Hartley. As a result of recent changes in the articles of association, the council of management will in future consist of the officers, six elected members and seven members nominated by the Lord President of the Council to represent general scientific and public opinion. The elected members are B. Chibnall, Dr. R. C. MacKeith, J. Maddison, C. A. Ronan, C. H. Sylvester and R. A. Williams; the members nominated by the Lord President are Mrs. Jacquetta Hawkes, Dr. F. H. K. Green (Medical Research Council), Dr. Alexander King (Department of Scientific and Industrial Research), Sir Ian Orr-Ewing, J. Ryan, Sir William Slater (Agricultural Research Council) and Sir Robert Watson-Watt. The address of the Association is 164 Shaftesbury Avenue, London, W.C.2.

## Direct Reading Emission Spectroscopy

THE Industrial Spectroscopy Group of the Institute of Physics has formed a panel of members interested in direct-reading equipment for spectrochemical analysis. These devices combine spectrographs with electronic equipment in such a way that the intensities of characteristic spectral lines give a direct reading of the percentage of the elements present in the specimen. The object of the panel is to organize meetings which would serve the interests of users and potential users of this equipment. The first meeting arranged by the panel took place in the Institute's House on March 26 last, when Dr. A. C. Menzies introduced the subject. Mr. A. L. Pendrey and Mr. R. T. Staples gave accounts of their experiences in this type of work, and there followed a general discussion. Particulars relating to meetings on this subject can be obtained from the Secretary, Institute of Physics, 47 Belgrave Square, London, S.W.1.

## Handbook of Scientific Instruments and Apparatus

THE annual "Handbook of Scientific Instruments and Apparatus", giving details of the exhibits at the Physical Society's annual exhibition, is now a publication familiar to all men of science and manufacturers of scientific instruments. This year's exhibition, the thirty-seventh of the series, is to be held at the Imperial College of Science and Technology, South Kensington, London, during Monday, April 13–Friday, April 17, and will be opened on April 13 at 10.30 a.m. by Prof. R. Whiddington, president of the Physical Society. Three discourses are being given this year: (1) Dr. E. C. Bullard (director of the National Physical Laboratory) on "Seismic Study of the Ocean Basins"; (2) Dr. L. A. Jordan (director of the Paint Research Station) on "Particles, Pellicles; Pigments, Paints and Physics"; and (3) Prof. W. V. Mayneord (Department of Physics, Royal Cancer Hospital) on "Scintillation Counting and its Medical Applications". The prize distribution of the Craftsmanship and Draughtsmanship Competition will take place during the exhibition on April 13 at 5 p.m. The handbook, a volume essential to all workers interested in the progress and development of scientific instruments, gives instructive descriptions of the many instruments shown by about a hundred and fifty exhibitors, including government research establishments. This extremely useful volume, which is now available, is printed on glossy paper and is illustrated by numerous half-tone reproductions of scientific instruments. It should be in the hands of all physicists and scientific workers who use or design scientific instruments (pp. xii+262+A72. Physical Society, 1 Lowther Gardens, Prince Consort Road, London, S.W.7. 6*s*., or 7*s*. 3*d*. post paid).

## Announcements

SIR HENRY BERESFORD-PEIRSE, director of forestry for Scotland since 1947, has been appointed deputy director-general of the Forestry Commission. He will be succeeded in Scotland by Mr. A. H. H. Ross, at present conservator of forests for north-west England.

THE following have been appointed lecturers in the Queen's University of Belfast: S. McConaghy (agricultural chemistry), R. E. Parker and Dr. E. W. Simon (botany), and Dr. I. Leslie (biochemistry).

THE Commonwealth Fund (35 Portman Square, London, W.1) has awarded the following Home Civil Service Fellowships to British Civil servants for study in the United States during 1953–54: B. R. Feaver (Forestry Commission (Scotland)), G. Leitch (Ministry of Supply), L. S. Mills (Ministry of Civil Aviation) and P. E. Watts (Ministry of Fuel and Power).

THE Bone and Tooth Society will hold a symposium on "Vitamin C and Bone" on April 9 at the Institute of Orthopædics, 234 Great Portland Street, London, W.1. Dr. E. H. Allen will speak on "X-Ray Findings in Scurvy"; Dr. L. E. Glynn on "Vitamin C and Ground Substance"; Dr. G. H. Bourne on "Vitamin C and Ossification"; and lastly Dr. B. E. Clayton on "Cortisone and Vitamin C".

THE Ministry of Agriculture and Fisheries and the Department of Agriculture for Scotland propose to award, for the academic year beginning October 1, 1953, or earlier, a limited number of postgraduate scholarships in agricultural economics, husbandry, statistics, and agricultural and dairy engineering. The closing date for applications is May 1. Further particulars can be obtained from the Secretary, Ministry of Agriculture and Fisheries (Research Branch), 1–4 Cambridge Terrace, Regent's Park, London, N.W.1, or the Secretary, Department of Agriculture for Scotland, St. Andrew's House, Edinburgh 1.

A SCIENCE Meeting of the Physical Society will be held at the Imperial College of Science and Technology, London, S.W.7, during May 15–16, the subject of which will be "Recent Research in Electron Optics". The meeting is being arranged by Dr. O. Klemperer, of the Imperial College, and will be divided into seven sections as follows: electron lenses; correction of aberrations; electron guns; focusing in electron accelerators; electron optics in television tubes and valves; electron spectrometry; other subjects. Visitors wishing to attend this meeting should apply to the offices of the Physical Society, 1 Lowther Gardens, Prince Consort Road, London, S.W.7, for further particulars; the closing date for applications is May 7.

# SHEEP BIOLOGY LABORATORY, PROSPECT, NEW SOUTH WALES

By Prof. C. W. EMMENS

Department of Veterinary Physiology, University of Sydney, and Officer-in-charge of the Prospect Laboratory

THE Wool Use Promotion Act 1945 and the Wool Industry Fund Act of 1946, of the Commonwealth Government of Australia, made provision for additional funds to be devoted to the expansion of sheep and wool research. As a result of a survey made by the Commonwealth Scientific and Industrial Research Organization, it was clear that, although considerable progress had been made in the control of the diseases of sheep, relatively little had been achieved in the improvement of the productivity, including fertility, of the healthy animal.

It was therefore decided to found, within the Division of Animal Health and Production, a Sheep Biology Laboratory where problems of this sort would be tackled. A site of 116 acres was selected at Prospect, New South Wales, about twenty miles from Sydney, and acquired in September 1946. Plans were made to start work and to extend existing programmes without waiting for certain of the facilities at Prospect. Units eventually to move into the Sheep Biology Laboratories were strengthened, and new ones were set up in various other centres in Victoria and New South Wales. These have grown to such an extent that the staff destined for Prospect already amounts to some seventy or eighty persons.

The most important buildings, some of which are yet to be constructed, are as follows.

*Animal houses.* These are primarily intended to house sheep in single pens, or small multiple pens, and, so far, one has been constructed. Each is 282 ft. long by 40 ft. wide and accommodates about a hundred and fifty animals. At each end of these houses are offices, record rooms and various other servicing units.

*Fleece and shearing building.* This is 150 ft. by 40 ft. and is to be used for handling fleeces from shearing to storage, with air-conditioned laboratories attached for the study of fleece samples under standard conditions. It is ready for use.

*Climate control and examination building.* This will be a two-story building, 182 ft. long by 45 ft. wide, containing two climate-control rooms, each 13 ft. by 24 ft., and a larger preconditioning room of 24 ft. by 37 ft., small animal colonies, a clinical wing with operating theatre and associated rooms, and an X-ray unit as well as a photographic studio. In the climate-control rooms any prescribed climatic conditions will be maintained, and the rest of the building will have appropriate air conditioning.

*Prefabricated buildings.* These comprise two aluminium buildings, each 153 ft. by 40 ft., to be used as laboratories, stores, canteen, etc., while the main laboratory is under construction. They are nearly ready for occupation, and will house the first groups of workers mentioned above. When the Main Laboratory is ready, most of the workers will move into it; but some may remain in the prefabricated buildings.

*Main laboratory building.* This will be of two stories, approximately 215 ft. by 42 ft., with a single-story library wing. It will house the main group of laboratories, offices, library, records and storage rooms. Both this and the prefabricated buildings will be air-conditioned.

Other buildings, covering with those already specified an area of about five acres, are a large garage and workshop, a feed store, and various smaller sheds and houses for miscellaneous equipment. The main buildings will eventually be connected by covered ways giving sheltered access to almost any of the central group of facilities.

The following existing Research Sections will be housed in the Prospect Laboratories as soon as possible.

*Wool Biology.* This is a Section with an essentially long-range programme of work, directed in the first instance to the study of the skin and the fleece of sheep, but on a comparative basis. At present, the work of the Section falls under six main headings: the comparative development of the skin in sheep and other mammals, with special reference to the hair follicle group and its associated glands; the physiological mechanisms associated with skin, particularly with the growth of wool and the activity of the sebaceous and sweat glands; genetic effects on the growth and development of skin and their interactions with the above; the efficiency of fleece production in different breeds and strains; aspects of the physiology and anatomy of heat regulation in different breeds and strains; the relationship between fleece types and such environmental factors as nutrition, temperature and illumination.

*Fleece Analysis.* This is a Section responsible for the study and development of methods of measuring fleece characteristics, such as fibre length, fibre diameter, fleece density, and the variability associated with them. This Section already makes many thousands of examinations a year in association with the experimental programmes, mainly field studies, of other Sections or outside organizations, while simultaneously developing its own research programme. Physicists from this Section will also be responsible for the running of the climate-control rooms.

*Reproductive Physiology.* Two small groups of research officers and one or two isolated research workers form the nucleus of the Prospect team. At present they are working on the following lines: problems connected with the occurrence and distribution of matings in flocks under different conditions, and of subsequent pregnancies; the capacitation phenomenon in spermatozoa; problems connected with reproduction in the domestic fowl; and the preservation of semen under refrigeration. Most of these workers have also been concerned with investigations in the infertility of sheep on subterranean clover pastures, in collaboration with university research teams, a project which has resulted in the isolation of genistein, an œstrogenic *iso*-flavone, from the affected pasture.

*Ruminant Digestion and Physiology.* In this Section the sheep is taken as the main experimental subject; work is already in progress on the digestion of protein and on the metabolism of carbohydrate and fat. It is planned to expand these researches and to build up a team of investigators whose broad terms of reference will be physiological problems especially related to the ruminant.

*Field Studies.* The new laboratory will act as a centre, not only for laboratory research, but also for the organization of field trials, observations of stud and other practices, and for the collection of information from all possible sources. Officers of the present Wool Biology Section are now active in this field; in addition, they and others are collaborating in projects known as the 'strain trials', in which the performance of five different strains of merino sheep is being studied at three different localities in the eastern half of Australia. The trial will continue for many years. Such field studies as these are often best interpreted in the light of concurrent work on the smaller, closely controlled groups of animals for which the facilities of the Sheep Biology Laboratory were designed.

Following the lead of institutions like Rothamsted Experimental Station in Britain, the Sheep Biology Laboratory will develop a strong statistical section. Other aspects of its present structure that will be strengthened are the more biochemical and biophysical parts of the work. The exact degree to which it may participate in work of a more-or-less purely genetic nature will depend on its relationship with the newly formed Section of Animal Genetics of the Commonwealth Scientific and Industrial Research Organization, part of which may also be located at Prospect.

## BRITISH COMMONWEALTH GEOLOGICAL LIAISON OFFICE

During the recent nineteenth International Geological Congress at Algiers, the first meeting of the British Commonwealth Committee on Mineral Resources and Geology was held in the British Consulate Office, at which the following representatives of their respective Geological Surveys attended: Mr. C. J. Sullivan (Australia), Dr. J. W. Harrison (Canada), Dr. F. Dixey (the Colonies), Dr. B. C. Roy (India), Dr. N. M. Khan (Pakistan), Dr. A. M. MacGregor (Southern Rhodesia), Dr. L. T. Nel (South Africa), Dr. W. J. Pugh (United Kingdom) and Mr. R. W. Willett (British Commonwealth geological liaison officer).

The British Commonwealth Geological Liaison Office and the British Commonwealth Committee on Mineral Resources and Geology were set up on the recommendation of the 1948 Specialist Conference on Mineral Resources and Geology, the purpose and scope of the office being defined in the report of that Conference (Code No. 47–149. London: H.M.S.O., 1949). As a result, the Geological Liaison Office was established in May 1951 at the British Commonwealth Scientific Offices, Africa House, London, and at the same time the present British Commonwealth geological liaison officer, R. W. Willett, of the New Zealand Geological Survey, commenced duties.

The recommendations of the 1948 conference were as follows. (*a*) Permanent Commonwealth machinery should be set up to promote collaboration and interchange of information between government organizations concerned with the investigation of geology and mineral resources throughout the British Commonwealth. This machinery should take the form of a Committee, to be known as the Committee on Mineral Resources and Geology, with members representative of such organizations from each of the participating countries meeting at intervals of not more than three years in a Commonwealth country. (*b*) The permanent executive and secretarial work of this Committee should be under the direction of a senior officer with appropriate technical qualifications stationed in London, who would be known as the British Commonwealth geological liaison officer. His duties would include: acting as a liaison officer in matters pertaining to geology and mineral resources for all participating members of the British Commonwealth; taking appropriate action to give effect to the recommendations of the present Conference; and making the preliminary arrangements for the periodical meetings of the Committee.

Dr. W. J. Pugh, director of the Geological Survey of Great Britain, was elected chairman and will now hold office until the Committee meets again, which will be when a suitable and appropriate occasion offers. The Committee reviewed and discussed the annual report of the Geological Liaison Officer, and the progress made in translating into action the original recommendations, and endorsed the action taken; as a result, it recommended the continuance of the Geological Liaison Office along the lines already laid down. The geological liaison officer is appointed for three years, at the end of which period he is replaced by another Commonwealth officer selected and appointed in the same manner. The first annual report of the Office was presented at a recent meeting of the Committee, and in it the scope and extent of the work of the Office were outlined.

As a background to the work of the Office, a series of reports are being prepared on the mineral resources of the British Commonwealth. These reports present the essential quantitative and qualitative information on the various mineral deposits in the Commonwealth and are based on the latest published information and on unpublished information, obtained by correspondence where necessary, with various Commonwealth Surveys. So far, nineteen metals and non-metals have been covered in this manner—namely, copper, lead, zinc, cobalt, nickel, antimony, manganese, tungsten, vanadium, molybdenum, chromium, beryllium, zirconium, titanium, niobium and tantalum, phosphates, sulphur and asbestos. These are circulated to the United Kingdom Ministries concerned, to members of the Commonwealth Committee on Mineral Resources and Geology, the Defence Advisory Committee on Commonwealth Mineral Resources and to the Commonwealth scientific liaison officers at Africa House, London. It is hoped to cover the entire field of industrial minerals and rocks and, with certain modifications, to publish these reports in the form of a single volume.

Some preliminary action is being taken on the subject of the presentations of mineral statistics, in order to explore the possibility of greater uniformity in the use of units and methods of presentation. The recommendation of the 1948 Specialist Conference asking all Commonwealth countries to prepare and issue an annual volume of abstracts of geological papers of the territories under their control has not yet been put into action by all the countries concerned. In order to assist in this work, the Geological Liaison Office has prepared such a volume of United Kingdom abstracts for 1951 for limited distribution, which will be followed by that for 1952. If this experiment is successful, an attempt will be made to extend this work to those countries of the British

Commonwealth which are not already preparing their own annual volumes of abstracts.

The geological liaison officer serves on a number of committees concerned with mineral resources, their development and utilization. The officer, as a specialist on the subject of geology and mineral resources, also acts in close liaison with the scientific liaison officers of the other Commonwealth countries, and at the same time close liaison is maintained with the Ministry of Materials, Department of Scientific and Industrial Research and other Ministries in Great Britain which are interested in the mineral resources and their availability throughout the Commonwealth. Reports and accounts of meetings and conferences concerned with geology and mineral resources are also prepared and circulated to the Commonwealth countries.

Close contact is maintained by the Geological Liaison Office with the Colonial Geological Surveys Directorate, as the two organizations are in a sense complementary; the latter links all the Colonial Geological Surveys, while the former is an attempt to link, in a less formal way, the Commonwealth Geological Surveys. The Geological Liaison Office is now charged, as a result of recommendations by the British Scientific Official Conference in Australia, with the formation of Commonwealth collaboration on geophysical prospecting, and the beneficiation and utilization of low-grade ores. The Office is now firmly established as an intrinsic part of the British Commonwealth Scientific Office, and, as an experiment in a purely Commonwealth organization, appears to be functioning with some measure of success.

# RECORDING OF RESEARCH AND ITS PATENT ASPECTS

MANY research workers, more usually the younger ones, dislike keeping adequate records of their investigations, but the fact has to be faced that the keeping of proper records is probably much more important, and a much less simple obvious matter, than is often supposed. Various aspects of the subject were discussed last year by a joint committee of the Franklin Institute and of the American Patent Law Association in a programme entitled "Who is the First Inventor?"; and further consideration has been given in a recent timely and interesting article by J. G. Jackson, on "Records of Research" (*J. Franklin Inst.*, 254, 355; 1952).

There are, of course, several sound reasons for keeping good records, many of which are sufficiently obvious without undue elaboration. (*a*) Avoidance of duplication, especially in prolonged research, when problems may again crop up that have been already studied and not recorded. (*b*) Taking full advantage of negative results, which also may prevent duplication if properly noted at the time. (*c*) Assisting the development of a fundamental approach, for very often at the start the workers are somewhat in the dark, or are taking part in one small section of a comprehensive programme, so that they think their results are relatively unimportant and not worth reporting; but such data later on prove essential in developing a theory or fundamental approach. (*d*) Publication; when work is published or reported at a meeting, supplementary questions arise which cannot be answered because full data have not been recorded. (*e*) Patent requirements; for example, insufficient record prevents the inventor from establishing that he was the first inventor, and it may thus happen that the company which developed the subject-matter may be forced to take a licence under someone else's patent.

The very minimum of information that should be recorded is the date of commencement of work, by whom it is done, detailed account of the work (with date of each important step) and the results. Such recording may often be the proper function of the research director or group supervisor. For patent purposes it is absolutely essential that provision be made for corroboration, and this is discussed at some length by Mr. Jackson. Some useful practical notes on this part of the subject can be found elsewhere[1,2].

Certain milestones in connexion with research in industry should be formalized, to enable firms to determine the progress being made and the status at each stage. These formal steps are very helpful in tying together various records for patent purposes; and assigning project numbers is, for the same reason, of great assistance.

Several valuable suggestions on the keeping of laboratory notebooks are given: step-by-step records in order of time; making of sketches and drawings; issuing a specification on an item under development before it is standardized (which constitutes a valuable record of research); photographs and samples; and codes and abbreviations. These last-named may often be the cause of much trouble and confusion, some curious examples of which are given. Special records may sometimes be required from the point of view of patents, on which much useful advice is provided. Finally, it is pointed out that publications perform certain functions as research records, and have a special significance in patent matters.

# ELECTRONIC DIGITAL COMPUTERS

## CONFERENCE IN THE UNITED STATES

IN 1950 a meeting was held in Atlantic City, N.J., to discuss electron tubes for computers. The meeting was initiated by Dr. A. L. Samuel, as representative of the Research Development Board, and was sponsored by the American Institute of Electrical Engineers and the Institute of Radio Engineers. The success of this initial meeting led Prof. J. G. Brainerd to suggest the formation of a joint computer conference committee between these two last-named bodies in order to consider whether further meetings should be held and, if so, on what subjects. It was decided that the subjects which required urgent attention were electronic digital computers, input and output equipment, high-speed memory and choice of number system. Accordingly, the joint conference held in Philadelphia, Penn., during December 10–12, 1951, dealt with the first topic, and a recent conference, during December 10–12, 1952, at New York City, was concerned with input and output equipment.

The 1951 meeting, at which the Association for Computing Machinery also co-operated, attracted an attendance of 877 members, and the eighteen papers and discussions that were presented have recently been published*. Ten different large-scale electronic computers of varying design and performance are separately described. These are the UNIVAC, ORDVAC, EDSAC, SEAC, ERA 1101, Burroughs Laboratory, Whirlwind I and the University of Manchester computers, and the IBM card-programmed and the Mark III electronic calculators. In other papers detailed operating and component experience on certain of these instruments is discussed. In addition, a report on the use of computing machines in aircraft engineering is given by C. R. Strong, of the Douglas Aircraft Co., the seven digital computers designed and built by the Bell Telephone Co. are described by E. G. Andrews, and the application of transistors to digital computation is discussed by J. H. Felker.

Finally, a summary of the present status and future trends of digital computers is given by J. W. Forrester, in which he states that it is clear that the pioneering days are over and that enough experience of the various models has now been gained to judge the adequacy of the designs. Though there are quite definite lines of development—for example, towards machines of still higher speed—it is worth while to note the concluding sentences of Mr. Forrester's summary which aptly summed up the position at the end of 1951: "Machine speed has increased by several orders of magnitude over the last ten years. In the future we can perhaps get another decade in speed, but I doubt that more can be accomplished without a fundamentally new type of computer. The great steps in the near future will be in the direction of simplification without losing performance. It seems clear that the complexity of computers can and must be reduced."

# PRODUCTION OF HIGH VACUA BY IONIZATION

A LITTLE while ago, Dr. A. von Engel directed attention to the method of obtaining high vacua by ionization (*Vacuum*, 1, No. 4; Oct. 1951); it is therefore of interest to note that a discussion of the principles and limitations of such pumping action, together with a description of an electronic pump which was the subject of a German patent in 1943, is given in a paper by H. Schwarz*.

The idea of obtaining high vacua by ionization is, of course, quite old and well known, and the clean-up, that is, absorption of gases or vapours, in an electrical discharge is a common experience and fairly well understood. Dr. Schwarz, however, shows theoretically that it is not possible, even under the most favourable conditions, to construct a high-vacuum pump with reasonable dimensions utilizing a normal D.C. gas discharge. A real pumping action can only result when there is such a high ion-current that the number of ionized gas molecules transported in one direction is greater than the number of gas molecules diffusing back in the opposite direction. It is necessary, therefore, to increase the path of the electrons without increasing the length of the tube, and this may be accomplished either by making the electrons oscillate on screw paths about the tube axis, or by using an external magnetic field which forces the electrons to travel in spiral paths within a cylindrical electrode system, as in the magnetron or cyclotron.

The model of an electronic pump which Dr. Schwarz describes consists of an incandescent cathode, a ring-shaped anode at about 2,000 V. and a third annular electrode at cathode potential. The 10-mA. electron current is kept oscillating through the anode, and a magnetic field parallel to the tube axis keeps the electrons on spiral paths at the centre of the tube away from the anode. Special arrangements are made to remove absorbed gas from the glass walls of the tube and to prevent ions from diffusing back into the high-vacuum side. As a test of the pump, a volume of half a litre was pumped down from a pressure of $10^{-3}$ to $10^{-5}$ mm. of mercury in less than one second.

# CULTIVATION OF SULPHATE-REDUCING BACTERIA

By JOY P. GROSSMAN and DR. JOHN R. POSTGATE

Chemical Research Laboratory, Teddington, Middlesex

STUDIES on the bacteriology and biochemistry of the sulphate-reducing bacteria have long been obscured by inconsistencies in the behaviour of these organisms. For example, tests on the ability of a single strain to utilize various sources of carbon may give different results on different occasions; subcultures sometimes fail to grow, or grow with a very long lag, for no obvious reason; dilution counts on a motile and obviously healthy population indicate that rarely more than 10 per cent and often as little as 0·01 per cent of these cells are apparently viable; strains grown with excess of ferrous ions in the medium often do not grow readily without this; and so on. Though the capriciousness of these bacteria has not often been described explicitly in the literature, it is common experience among workers in the field. The observations described below to some extent clarify the situation. Since they bear closely on the work of other laboratories studying these bacteria, and since they have required a re-assessment of earlier work in this laboratory, we have felt that this preliminary report is desirable.

The fundamental observation, that reducing agents stimulate the activities of these bacteria, has been reported by many sources, including this laboratory[1–4], and the importance of a negative redox potential for their effect in anaerobic corrosion was emphasized by Starkey and Wight[5].

*Methods.* Strains of *Desulphovibrio desulphuricans* were cultured at 30° C. in anaerobic jars containing hydrogen plus 5 per cent carbon dioxide or in sealed test-tubes containing a plug soaked in pyrogallol with strong sodium carbonate. For normal subcultures a 1/100 dilution of a grown culture was made into fresh medium. Dilution counts were performed in duplicate by making serial 1/10 dilutions in the appropriate medium using a fresh pipette at each stage. Direct counts were made through the microscope using a 0·02-mm. depth Thoma hæmocytometer; dilutions for this purpose were prepared in 0·8 per cent saline and were either counted at once or after storage in ice to prevent cell multiplication.

*Results.* Sodium sulphide (5 µmol./ml.) added to either a peptone–yeast–glucose medium[5] or to Starkey's medium supplemented with yeast extract[4] permitted full growth of *D. desulphuricans* (Hildenborough strain) in 16–24 hr. with the conventional inoculum. Without sulphide, growth required 2–3 days, though it could be accelerated by using a larger inoculum. The stimulant effect of sodium sulphide has been observed with at least eight other strains; lower concentrations of sulphide were not effective in our experiments.

Dilution counts in either of these media supplemented with sodium sulphide gave results in agreement with the direct count. For example, in a glucose–peptone–yeast medium, dilution counts on a culture containing $(3 \pm 1) \times 10^8$ cells/ml. (direct count) gave counts indicating $10^8$ viable bacteria/ml. if sodium sulphide were present, though in its absence counts of $10^4$, $10^7$ and $10^8$ viable cells/ml. were found in three separate series. Sulphide could be replaced by cysteine, ascorbic acid or glutathione, so its effect on growth and viability was due to its reducing properties. Ascorbic acid and glutathione appeared less effective than cysteine or sulphide, and cysteine had the advantage that it could be used in the presence of excess ferrous ions to enable one to detect growth by blackening of the culture due to formation of ferrous sulphide. Dilution counts in media containing cysteine (5 µmol./ml.) plus ferrous ammonium sulphate (1 µmol./ml.) gave results in satisfactory agreement with the direct count using a pure strain of *D. desulphuricans*, and counts on polluted waters indicated populations considerably in excess of those found with unsupplemented media. In two cases sulphate reducers were detected only with cysteine–iron media. In certain natural waters and soils, however, there is a risk that bacteria able to decompose cysteine will liberate hydrogen sulphide and give false results. This counting procedure is being studied further and will be reported in detail elsewhere. The effect of cysteine or sulphide is not directly connected with sulphate reduction, since strains that can grow without sulphate[7] are stimulated if cysteine or sulphide is added to sulphate-free pyruvate media.

*Conclusions.* Sulphate-reducing bacteria grow much more rapidly if a sufficient concentration of a reducing agent such as cysteine or sulphide is added to the medium. Small populations will often not grow at all without these supplements, so dilution counts, even of large populations, do not measure the population being counted unless a reducing agent is added to each dilution.

Besides providing a reliable method of counting pure populations of *D. desulphuricans*, these observations have several practical consequences relevant to the routine handling of these bacteria.

(i) *Irregularities of growth.* Since sulphide is an end-product of growth in ordinary media, the carry-over of sulphide in the inoculum will determine the rate at which the subculture will grow. In certain cases (a moribund culture, or one from which all sulphide has been removed by alkali in the plug, lead acetate or ferrous salt), the carry-over may be insufficient to allow growth at all. A particular case in which this is important is in the revival of lyophilized cultures, which grow most irregularly unless cysteine or sulphide is added.

(ii) *Effect of ferrous ions.* Excess ferrous salt is often added to a medium in order to detect growth by blackening due to ferrous sulphide, and many workers have noticed casually that growth may occur more readily with excess ferrous ions than without, though this phenomenon does not occur regularly. Since the ferrous ion is a reducing agent, it could act as a stimulant like sodium sulphide or cysteine, and, if the carry-over of sulphide from the parent culture were low, it might have sufficient reducing effect to stimulate growth.

(iii) *Apparent populations of sulphate reducers.* The population of sulphate reducers indicated by dilution counts with unsupplemented media cannot be expected to equal the actual population, and in our experience bears no constant relation to it. Allen[6] mentioned this discrepancy in his studies on sulphate-reducers in sewage, but Heukelekian[8] considered that his counts represented actual populations.

(iv) *Inoculum size.* The rate at which a culture grows in an unsupplemented medium depends on the carry-over both of sulphide and of cells; in media supplemented with cysteine or sulphide it depends only on the number of cells. Hence, in supplemented media, the large inoculum conventionally used with these bacteria is unnecessary. For quantitative work this can be important, as the carry-over of metabolites and end-products in the conventional inoculum must be absurdly large compared with the carry-over in work on other bacteria.

(v) *Aerobic growth.* Butlin, Adams and Thomas[4] showed that addition of ascorbic acid to cultures would permit growth of these bacteria in air. By producing sulphide the sulphate-reducing bacteria create reducing and anaerobic conditions wherever they are active, and, though obligate anaerobes, are thus capable of growth in air if access of air to their immediate environment is slow. They can be grown in air in deep tubes or flasks if a large inoculum is used, or if sulphide is added, and once growth starts it follows diffusion of sulphide throughout the medium. This fact may account for reports of aerobic growth of this organism such as that of Shturm[9].

(vi) *Growth in agar.* The effect of sulphide or cysteine is equally pronounced in media set with agar, and, if sodium sulphide (20 µmol./ml.) is added to the appropriate agar medium, these bacteria can be maintained on the surface of agar slopes protected from oxygen by a pyrogallol plug. Normally it is extremely difficult to grow them on agar slopes. In deep agar 'shake' cultures without sodium sulphide or cysteine, growth of colonies tends to occur in masses: colonies grow more readily if other colonies are near at hand. This phenomenon was noted by Baumann and Denk[10], who ascribed it to diffusion of nutrients from colony to colony. The phenomenon is more likely to be due to diffusion of sulphide, since it can be abolished by addition of cysteine or sulphide to the agar.

The isolation of pure strains can be difficult, since, though in an enrichment the population of *D. desulphuricans* may outnumber the population of contaminants, the proportion that grow in an unsupplemented agar 'shake' may often be less than the proportion of contaminants. The addition of cysteine and iron to agar media has greatly facilitated isolations in our laboratory, since it ensures that all the sulphate reducers present actually form colonies.

In consequence, colonies well separated from contaminant organisms are more readily obtained.

(vii) *Requirement for a reducing agent.* One strain in our laboratory (New Jersey S.W.8, kindly provided by Prof. R. L. Starkey) appears to be unable to grow without a reducing agent. It grows normally in media containing excess ferrous ammonium sulphate, and this can be replaced by cysteine, sodium sulphide or ascorbic acid. We have not succeeded in maintaining it in media without a reducing supplement, even with the conventional large inoculum.

(viii) *Growth with various carbon sources.* The ability of *D. desulphuricans* to grow with various sources of carbon was described exhaustively in the classical work of Baars[11]; Stephenson and Stickland[12] regarded their strain as different from Baars's because of its different 'spectrum' of carbon utilization. Senez[13] studied a strain which would utilize only a few carbon compounds, and Pochon and Chalvignac[14] showed that the ability to utilize carbon sources depended on: (*a*) how long the organism had been subcultured with a single carbon source, and (*b*) whether yeast extract was present in the test media. Our studies have confirmed Pochon and Chalvignac's second point, but have also shown that the presence or absence of sulphide in the test medium influences the results. This observation is well exemplified by tests of carbon utilization by our strain El Agheila *Z*[7,15] which are recorded in Table 1. When cultured with neither yeast extract nor sulphide, the strain grew with very few substrates and required the conventional large inoculum. Addition of sodium sulphide increased the number of substrates utilized and permitted the use of a small inoculum. Addition of yeast extract did not abolish the need for a large inoculum, but increased the range of substrates attacked. With both yeast extract and sodium sulphide, using a small inoculum, a much wider range of substances was attacked. With certain of the carbohydrates, limited growth (presumably utilizing oxidizable carbon in the yeast extract) occurred immediately, but full growth was delayed for many days.

These observations show clearly that growth tests with various sources of carbon in unsupplemented media cannot be used satisfactorily for distinguishing between strains and species of *Desulphovibrio* unless the carry-over of sulphide and nutrients in the inoculum is very carefully defined, and also the presence or absence of other reducing agents such as ferrous ions.

Table 1. GROWTH OF *D. desulphuricans* (STRAIN EL AGHEILA *Z*), NORMALLY CULTURED IN LACTATE MEDIUM, IN MEDIA CONTAINING VARIOUS SOURCES OF CARBON IN PLACE OF LACTATE

All media contained sodium chloride (2·5 per cent), sodium sulphate and other salts at *p*H 7·6 (see ref. 7). Carbon sources 1 per cent except lactate, pyruvate, malate and ethanol (81 µmol./ml.). Sodium sulphide 5 µmol./ml. when present, yeast extract ('Difco') 0·1 per cent when present. Incubation, 30° C. for 14 days in nitrogen

| | No supplement | Sodium sulphide | Yeast extract* | Yeast extract* + sodium sulphide |
|---|---|---|---|---|
| Inoculum (dry wt./ml.) | 2 µgm./ml. | 10 mµgm./ml. | 2 µgm./ml. | 10 mµgm./ml. |
| Lactate | + | + | + | + |
| Pyruvate | + | + | + | + |
| Malate | . | . . | + | + |
| Ethanol | . | . . | + | + |
| Glycerol | – | + | + | + |
| Glucose | – | – | – | + |
| Galactose | – | – | – | + |

| Mannitol | – | – | – | – |
| Acetate | – | – | – | – |
| No substrate | – | – | – | – |

* '+' in these columns indicates growth in excess of that supported by the yeast extract present.

(ix) *Cysteine requirement.* Postgate[6] reported that the growth of the Hildenborough strain of *D. desulphuricans* was stimulated by a mixture of four amino-acids, of which cysteine was the most important as their effect could not be observed in its absence. In the light of the observations reported above, it was possible that cysteine was not acting as a nutrient at all, but merely stimulating growth with the other three amino-acids through its reducing properties. We have shown that this is, in fact, true: Table 2 indicates that the improved growth found in an allotrophic medium supplemented with cysteine, serine, ornithine and *iso*-leucine was also obtained if cysteine was replaced by approximately equimolar sodium sulphide.

Table 2. GROWTH OF *D. desulphuricans* (STRAIN HILDENBOROUGH) IN AN AMINO-ACID MEDIUM WITH SULPHIDE IN PLACE OF CYSTEINE

The medium contained glucose (1 per cent), sodium sulphate and other salts (ref. 6) and was inoculated with 1 µgm. dry weight cells/ml. washed by centrifugation in 0·8 per cent sodium chloride. All amino-acids 1 mgm./ml. except cysteine (2 mgm./ml.); sodium sulphide, $10^{-3}$ *M*. Incubation, 30° C. for four days in hydrogen + 5 per cent carbon dioxide

| Supplement | Growth (µgm. dry wt./ml.) |
|---|---|
| — | 0 |
| Cysteine, serine, ornithine + *iso*-leucine | 115 |
| Sodium sulphide, serine, ornithine + *iso*-leucine | 120 |

We are indebted to Mr. K. R. Butlin for his advice and interest. This paper is published by permission of the Director, Chemical Research Laboratory.

# NARCOTICS AND BIOLOGICAL ACETYLATIONS

By W. J. JOHNSON* and PROF. J. H. QUASTEL, F.R.S.

Research Institute, Montreal General Hospital, Montreal

MUCH evidence[1] has accumulated to show that narcotics, at the low concentrations that produce narcosis *in vivo*, inhibit certain respiratory processes, particularly those involved in carbohydrate oxidation, in the nervous system and in other tissues. This has led to the view that narcosis may result from a suppression of certain respiratory events at the nervous centres where the narcotics are absorbed. On the other hand, Larrabee *et al.*[2] have pointed out that in experiments on resting neurones the functional effects of narcotics are apparently unaccompanied by a measurable retardation of the rate of oxygen consumption. With stimulated nerves, however, the inhibitory effects of a narcotic, such as chloretone, on the increased oxygen uptake are in proportion to their inhibitory effects on synaptic transmission. Bronk and Brink[3] have shown that the rate of oxygen uptake by resting (frog) nerve is reduced 15 per cent by 0·002 *M* chloretone, but that the increment in the rate of oxygen uptake obtained with nerves carrying impulses at the rate of 50 impulses/sec. is decreased by 50 per cent by the same quantity of narcotic. They conclude that the narcotic inhibits an enzyme in a reaction located between the oxidative reaction directly affected by the impulses and the reaction using oxygen.

* Canada Packers Research Fellow, McGill University.

It is important to realize, in our attempts to interpret the effects of drugs on metabolic processes, that it may be possible to impede a step in a chain of respiratory events, each of which contributes to the total quantity of oxygen consumed, without a large, or even measurable, effect on the rate of oxygen consumption by the cell, so long as the enzymes involved in the reactions following the impeded step are still saturated with their substrates. The step impeded, however, may be closely associated with a metabolic reaction directly involved in the functional activity of the cell.

It is proposed to show in this article that narcotics at low concentrations impede the oxidative synthesis of adenosinetriphosphate and, thereby, affect the rates of acetylation processes dependent on the presence of this substance. Eiler and McEwen[4] have already shown that pentobarbital inhibits the generation of high-energy phosphate bonds to the extent that it interferes with oxygen utilization. Brody and Bain[5] have, indeed, postulated that uncoupling of phosphorylation from oxidation may be connected with the narcotic action of barbiturates; but it will be shown, elsewhere[6], that the effects of narcotics on phosphorylations are quite different from those of a typical uncoupling agent such as 2 : 4 dinitrophenol.

## Experimental Procedure

The experimental work, carried out with the conventional Warburg apparatus at 37° C., involved a study of the effects of narcotics on rates of biological acetylations. These were brought about by various tissue preparations described as follows.

*Pigeon liver acetone powder.* Livers from freshly killed pigeons were minced and homogenized in the presence of acetone for 60 sec. in a Waring blendor. The homogenate was added to ten volumes of acetone (at 0° C.). After five minutes the dehydrated material was filtered on a Buchner funnel and washed with cold acetone. Drying of the powder was completed in a vacuum desiccator (over calcium chloride), where it was stored at 0° C.

*Pigeon liver extract.* The acetone-dried powder was extracted by grinding it for five minutes with 0·15 *M* potassium fluoride in the proportion of 60 mgm. of powder to 0·8 ml. of extraction medium. After centrifugation at 19,000 *g* for five minutes, the supernatant was filtered through glass wool, and 0·8 ml. of extract was pipetted directly into a manometer vessel.

*Rat brain homogenate.* A 25 per cent homogenate of rat brain was prepared by homogenizing the cerebral hemispheres in a solution composed of 0·06 *M* potassium chloride, 0·04 *M* nicotinamide, and 0·04 *M* magnesium chloride. 0 5 ml. homogenate was added to the manometer vessel.

In addition to pigeon liver extract and rat brain homogenate, the vessels contained 200 μgm. sulphanilamide, 0·02 *M* sodium phosphate buffer, *p*H 7 5, and other additions, as will be indicated, to a total volume of 3 ml. After five minutes of thermal equilibration, the measurement of oxygen uptake was commenced, carbon dioxide being absorbed by potassium hydroxide in the centre well of the manometric vessel. All the experiments were carried out in the presence of air.

*Rat brain mince.* Rat brain (cerebral hemispheres) was minced with a small Latapie mincer and suspended in a solution of 0 006 *M* nicotinamide, 0·15 *M* potassium chloride, and 0·02 *M* magnesium chloride, to make a 50 per cent suspension. 1 ml. of suspension was added to the manometric vessels after all other additions had been made. All the vessels contained the following substances (final concentrations) to a total volume of 3 ml.: sodium phosphate buffer, *p*H 7·4, 0·02 *M*; sodium fluoride, 0·03 *M*; choline chloride, 0·001 *M*; eserine sulphate, 0 0004 *M*; 0·2 ml. of 20 per cent potassium hydroxide in the centre well.

*Extracts of beef brain.* Acetone-dried beef brain was prepared according to the methods of Harpur and Quastel[7]. The acetone-dried brain powder was extracted by grinding it in a mortar with the following solution: nicotinamide, 0 08 *M*; neutral cysteine, 0·03 *M*; potassium chloride, 0·09 *M*; and magnesium sulphate, 0·012 *M*. After centrifuging for five minutes at 19,000 *g*, the supernatant was filtered through glass wool, and 1 ml. of the extract (equivalent to 60 mgm. of powder) was added to the manometric vessel after all other additions had been made. The vessels also contained the following salts (final concentrations) to a total volume of 3 ml.: sodium bicarbonate, 0·047 *M*; choline chloride, 0·0008 *M*; sodium phosphate buffer, *p*H 7·5, 0·01 *M*; eserine sulphate, 0·0003 *M*.

*Methods of analysis.* Acetylcholine was estimated by measuring the contractions of the dorsal muscle of the leech suspended in an aerated medium[8] of the following composition: sodium chloride, 0·71 per cent; potassium chloride, 0·032 per cent; calcium chloride, 0·018 per cent; sodium bicarbonate, 0·012 per cent; and glucose, 0·077 per cent. All the results are in terms of acetylcholine chloride. Phosphate esters were removed from the samples to be assayed by the procedure of Harpur and Quastel[7].

Sulphanilamide was estimated by the method of Bratton and Marshall[9]. Acetylated sulphanilamide was determined by difference.

## Effects of Narcotics on Acetylation

*Effects of chloretone and adenosinetriphosphate.* The addition of pigeon liver extract to rat brain homogenate produces a system which readily acetylates sulphanilamide under aerobic conditions. Rat brain homogenate alone is incapable of sulphanilamide acetylation, and does not hydrolyse acetylsulphanilamide. The results of a typical experiment, shown in Table 1, indicate the increase in acetylation obtained when acetate or pyruvate is added to the brain–liver system. It will be seen that pyruvate is more effective than acetate as an acetyl precursor for sulphanilamide acetylation, and that pyruvate, unlike acetate, gives rise to increased oxygen uptake. The addition of chloretone (0·004 *M*) reduces both

Table 1. Effect of chloretone on respiration and sulphanilamide acetylation by a mixture of rat brain homogenate and pigeon liver extract at 37° C. in air

| Additions | Oxygen uptake (µl.) | Inhibition of respiration (per cent) | Sulphanilamide acetylated (µgm.) | Inhibition of acetylation (per cent) |
|---|---|---|---|---|
| Nil | 183 | — | 36 | — |
| Chloretone (0·004 *M*) | 52 | 71 | 27 | 25 |
| Sodium acetate (0·02 *M*) | 185 | — | 81 | — |
| Sodium acetate (0·02 *M*) + chloretone (0·004 *M*) | 36 | 81 | 27 | 66 |
| Sodium pyruvate (0·02 *M*) | 345 | — | 108 | — |
| Sodium pyruvate (0·02 *M*) + chloretone (0·004 *M*) | 37 | 90 | 27 | 75 |

Vessel contents: 0·6 ml. rat brain homogenate and 0·8 ml. pigeon liver extract; sodium phosphate buffer, pH 7·5 (0·02 *M*); 200 µgm. sulphanilamide; and additions shown in table. Total volume, 3 ml.

Table 2. Effect of adenosinetriphosphate (ATP) in relieving the chloretone inhibition of sulphanilamide acetylation in a mixture of rat brain homogenate and pigeon liver extract in the presence of sodium acetate (0·02 *M*) at 37° C.

| Additions | Oxygen uptake (µl.) | Chloretone inhibition of oxygen uptake (per cent) | Sulphanilamide acetylated (µgm.) | Chloretone inhibition of acetylation (per cent) |
|---|---|---|---|---|
| Nil | 356 | — | 87 | — |
| Chloretone (0·004 *M*) | 143 | 60 | 27 | 70 |
| ATP (0·003 *M*) | 345 | — | 121 | — |
| Chloretone (0·004 *M*) + ATP (0·003 *M*) | 158 | 54 | 87 | 28 |

Vessel contents: as in Table 1, with diphosphopyridine nucleotide (0·00025 *M*) and additions shown above. Total volume, 3 ml. Experimental time, 90 min.

respiration and acetylation to low levels (Tables 1 and 2).

In the presence of added adenosinetriphosphate the extent of chloretone inhibition of acetylation is considerably diminished, while the rate of respiration is much less affected. A typical experimental result is shown in Table 2. It seems, therefore, that chloretone, by its inhibitive action on a respiratory process, inhibits the formation of adenosinetriphosphate and, therefore, the rate of synthesis of acetylsulphanilamide. The actual acetylating process is clearly far less affected by the narcotic, otherwise a relieving effect of adenosinetriphosphate would not be demonstrable.

Whereas adenosinetriphosphate, however, is effective in mainly overcoming the narcotic inhibition of acetylation in the presence of acetate, this is not the case when acetate is replaced by pyruvate (Table 3). Only a relatively small relief of the inhibition takes place. This is understandable, for as narcotics inhibit the pyruvic oxidase system in brain tissue[10–12], less oxidation of pyruvate occurs in the presence of the chloretone. There results, therefore, a diminution in the rate of formation of 'active acetate' required for acetylation purposes. The limiting factor becomes the availability of 'active acetate', and the addition of adenosinetriphosphate, under the given experimental conditions, influences this availability only to a small extent.

*Sulphanilamide acetylation by pigeon liver extracts.* Crude cell-free extracts of acetone-dried pigeon liver give rise to a high rate of sulphanilamide acetylation in the presence of acetate and adenosinetriphosphate. These extracts are also capable of a dismutation of pyruvate whereby 'active acetate' can be generated from pyruvate and produce acetylations in the absence of added adenosinetriphosphate. The acetylation is not due to residual adenosinetriphosphate in the crude extract, since the addition of acetate alone to the extract produces no appreciable increase in the rate of acetylation.

The results given in Table 4 show the effects of narcotics on the anaerobic acetylation of sulphanilamide by the cell-free extracts. No respiration takes place in these systems. The results indicate that the narcotics employed have no measurable effect on the rate of sulphanilamide acetylation. It may be concluded that the enzymes involved in the acetylation of sulphanilamide are not inhibited by narcotics even when these are present at relatively high concentrations. Furthermore, it is apparent that narcotics do not interfere with the utilization of adenosinetriphosphate. This is consistent with the fact that narcotics do not impede glycolysis, a process involving the utilization of this high-energy phosphate (Table 6).

*Aerobic acetylation of choline by rat brain mince.* Typical results of experiments dealing with the effects of narcotics on respiration and the acetylation of choline by rat brain mince are shown in Table 5. The addition of pyruvate increases the oxygen uptake, for example, by 109 per cent, this being accompanied by a 70 per cent increase in the rate of synthesis of acetylcholine. In all cases, the addition of the narcotic gives rise to a marked inhibition of the rates of oxidation and acetylation. It will be seen that the addition of adenosinetriphosphate increases the rate of acetylation of choline in the presence of the narcotic. It is clear, therefore, that the narcotic does not impede the utilization of the added adenosinetriphosphate; nor does it affect the choline acetylating system. The inhibition of choline acetylation by the aerobic respiring system is due, probably, to the suppression of adenosinetriphosphate formation, thus accounting for the parallelism between the percentage inhibitions of respiration and acetylation shown in the results given in Table 5.

*Acetylcholine synthesis by beef brain extracts.* The lack of inhibitory effect of narcotics on acetylcholine synthesis by cell-free extracts of beef brain is illustrated by the typical experimental results given in Table 6. It will be seen that a high concentration of 'Narconumal' (5-allyl-5-*iso*propyl-N-methyl barbituric acid) has no effect on acetylcholine synthesis by an extract of beef brain undergoing a high rate of glycolysis. This is also apparent in experiments where citrate is used as the acetyl donor and where the only high-energy phosphate available to the system is the adenosinetriphosphate initially added.

Harpur and Quastel[7] have shown that glucose does not inhibit acetylcholine synthesis by brain extracts,

Table 3. Effect of chloretone and adenosinetriphosphate on oxidation and sulphanilamide acetylation by a mixture of rat brain homogenate and pigeon liver extract in the presence of sodium pyruvate (0·02 *M*) at 37° C.

providing that conditions are present which allow glycolysis to take place. Under these conditions, the adenosinetriphosphate used in phosphorylating glucose is more than returned to the system. However, any interference with the phosphorylation mechanism associated with glycolysis would be reflected in a reduced acetylcholine synthesis. The fact that no inhibition of acetylcholine synthesis takes place indicates that the generation of adenosinetriphosphate in the course of anaerobic glycolysis is unaffected by the narcotic at the relatively high concentration used.

## Conclusions

These results show that an inhibition of respiration brought about by a narcotic is accompanied by a decreased rate of acetylation, and that the addition of adenosinetriphosphate to an aerobic system alleviates the narcotic effect on acetylation. The effect of added adenosinetriphosphate indicates that the narcotic inhibition of acetylation is the result of a suppression of the oxidative synthesis of this ester. Furthermore, it is apparent that narcotics at high concentrations affect neither the acetylating enzymes *per se*, nor the pyruvate dismutation system, nor the glycolytic sequence in beef brain extract. Thus, the narcotics do not inhibit the utilization of adenosinetriphosphate in these metabolic processes.

McLennan and Elliott[13] have postulated a direct effect of narcotics on the choline acetylating system to account for their results on acetylcholine synthesis, but our findings are opposed to such a conclusion. The underlying effect, which accounts satisfactorily for the results that have been described, is a narcotic-induced inhibition of the oxidative synthesis of adenosinetriphosphate. This is a phenomenon that must be concerned with the functional activity of the nerve cell, if acetylcholine, for example, plays the essential part in the nervous system which is claimed for it.

Table 6. Effect of narcotics on the anaerobic acetylation of choline by beef brain extracts at 37° C.

Vessel contents: 1 ml. of beef brain extract (≡ 60 mgm. powder) prepared as described in the text. Sodium bicarbonate (0·047 *M*), sodium phosphate buffer, *p*H 7·5 (0·01 *M*), choline chloride (0·0008 *M*), eserine sulphate (0·0003 *M*). Expt. 1 also contained diphosphopyridine nucleotide (5 × $10^{-4}$ *M*) and ATP (0·001 *M*); expt. 2 contained sodium fluoride (0·03 *M*). All gassed for 10 min. with 93 per cent $N_2$ and 7 per cent $CO_2$. Time, 1 hr. + 15 min. equilibration.

We are indebted to the Banting Research Foundation and to the Rockefeller Foundation for grants which made this work possible.

## Sulphur-containing Amino-acids of Nisin

In a recent publication[1], we reported that a preparation of the antibiotic nisin could be resolved into at least four active polypeptides, which all yielded on hydrolysis two sulphur-containing amino-acids not normally found in proteins. These amino-acids behaved like lanthionine and cystathionine on two-dimensional paper chromatograms, and treatment of a mixture of them with Raney nickel yielded two substances which behaved like alanine and α-amino-*n*-butyric acid.

The amino-acid which behaved like cystathionine has now been isolated and found to differ from cystathionine.

An acid hydrolysate of crude nisin was evaporated to dryness, the residue dissolved in water and the *p*H of the solution adjusted to 5·0. On standing at 4° C. a precipitate appeared which consisted mainly of leucine and valine. Addition of ethanol to the supernatant resulted in the precipitation of mixtures of lanthionine and the cystathionine-like substance. Fractional crystallization of these precipitates from water gave mainly lanthionine, while the other amino-acid remained in solution. The latter was precipitated by addition of ethanol and recrystallized from aqueous ethanol. Found: C, 35·4; H, 6·5; N, 11·3 per cent. $C_7H_{14}O_4N_2S,H_2O$ requires: C, 35·0; H, 6·7; N, 11·6 per cent.

Although this substance behaved like cystathionine on two-dimensional paper chromatograms, it was much more soluble than L-cystathionine in water. Dr. F. Gibson, of the Department of Microbiology, Oxford, found that it did not support the growth of mutant strains of *Bact. coli* which grew under similar conditions in the presence of a mixture of synthetic L-cystathionine and L-*allo*cystathionine. Moreover, it did not behave like cystathionine on a column of 'Dowex-50' (15 cm. × 0·9 cm.) when elution was carried out with the buffers used by Stein and Moore[2]. Lanthionine and cystathionine were readily separable on this column, the former emerging after only 12 ml. of the first buffer (*p*H 3·42) had passed through, and the latter requiring the passage of all the first buffer (34 ml.) and 13 ml. of the second buffer (*p*H 4·25) for elution. When a mixture of the two sulphur-containing amino-acids from nisin (precipitated from a hydrolysate as already described, but not fractionated) was run on the column, a well-isolated strong band corresponding to lanthionine was eluted; but no cystathionine appeared. Paper chromatography indicated that the cystathionine-like amino-acid was still present in the band containing the lanthionine.

These facts indicated that the substance was a structural isomer of cystathionine. This view was supported by the finding that it resembled lanthionine and differed from cystathionine in yielding a coloured solution ($E_{\text{max.}}$ = 450 mμ), when treated with the Chinard reagent[3]. This reagent has been used as a test for ornithine ($E_{\text{max.}}$ = 515 mμ); but it shows a weaker colour with lysine ($E_{\text{max.}}$ = 450 mμ), and it is of interest that lysine and lanthionine contain the same number of atoms between their two amino-groups.

The nisin polypeptides resemble the antibiotic subtilin, which has been shown to contain lanthionine and an amino-acid having the formula[4,5] $C_7H_{14}O_4N_2S$. We are grateful to Dr. J. C. Lewis, of the Western Regional Research Laboratory, U.S.A., for a specimen of this compound. X-ray powder photographs, kindly taken by Dr. D. Hodgkin and Mrs. M. Webster, of the Department of Crystallography, Oxford, have shown that it is identical with the corresponding amino-acid from nisin.

The $C_7$ amino amino-acid from subtilin has been found by Alderton[6] to yield L-alanine and D-α-amino-*n*-butyric acid on treatment with Raney nickel. However, the compound differs from L-*allo*cystathionine in having a higher optical rotation[5]. Alderton has therefore proposed that it is one of the β-methyllanthionines[6]. We conclude that this is also the structure of the amino-acid from nisin which was not distinguished from cystathionine by paper chromatography. It is of interest that nisin and subtilin both appear to contain β-methyllanthionine and lanthionine in the ratio of 4 : 1, although they differ in their content of other amino-acids[1,5]. These sulphur-containing amino-acids may also be present in a third polypeptide antibiotic, called cynnamycin, which has been obtained from *Streptomyces cinnamoneus*[7].

## The Fibrin Serum Factor

Until recent years, it was rather generally believed that the structure of a fibrin clot is held together by primary chemical bonds, as indicated, for example, by its failure to dissolve in concentrated neutral urea solutions. It is now known that fibrin can be prepared in two different forms, one of which contains much stronger bonds than the other. The latter is obtained from highly purified fibrinogen and thrombin; the former is prepared in the presence of small amounts of calcium salt and a yet unidentified component of serum. The fibrin prepared from purified components is soluble in dilute acid[1], neutral urea or neutral guanidine hydrochloride solution[2], or neutral solutions of lithium chloride, lithium bromide, sodium bromide and sodium iodide[3,4]. The fibrin with calcium and serum factor is resistant to all these reagents. The greater bond-strengths found in this fibrin compared with those in the clot obtained in the absence of calcium and serum factor are also shown by its higher rigidity and much slower stress relaxation[5]. This serum factor seems to be of protein nature, and is precipitated with fibrinogen in half-saturated ammonium sulphate, but not on isoelectric (*p*H 5·2–5·4) precipitation[6]. The purpose of the present communication is to report that this factor can be removed from fibrinogen preparations by exposure to several reagents, and that it can be restored by use of a purified albumin fraction.

Bovine Fraction I (Armour) was refractionated by a method essentially that described by Laki[7]; this consists of taking the supernatant solution from a low temperature, low ionic strength treatment and precipitating with 23 per cent saturation of ammonium sulphate. The *p*H is at all times above 5·9. The product generally has a clottability of 94–98 per cent; but, even at the highest degree of purity, serum factor is still present, since addition of calcium alone, usually employed at 0·001 *M*, will make the fibrin insoluble in urea solution. If the fibrinogen solution is exposed by dialysis to 3·0 *M* urea or to 2·0 *M* sodium bromide, the serum factor is destroyed, and addition of even 0·01 *M* calcium will not make the clot insoluble in urea. It should be mentioned that Loewy and Edsall have also observed the inactivation of factor activity by urea[8]. The experimental details are as follows. The buffer used as diluent and as solvent for the various proteins and the urea consists of 0·40 ionic strength sodium chloride plus 0·05 ionic strength sodium phosphate, giving *p*H 6·2. The sodium bromide reagent is dissolved in water. A 1–2 per cent fibrinogen solution is dialysed with constant stirring, against a large volume (changed once) of 3·0 *M* urea or 2·0 *M* sodium bromide for 6–8 hr. or 1–2 hr., respectively, at room temperature (23–26° C.), following which the reagent is removed by dialysis at 0° C. for 15–20 hr. against several changes of the 0·45 ionic strength buffer. Control samples are dialysed in a similar manner against the 0·45 ionic strength buffer. During none of these dialyses does precipitation or even opalescence appear in the samples. Ultracentrifugal patterns of material treated similarly show no change in the appearance of the single sharp peak seen[3,4]. Hence no appreciable damage seems to occur to the fibrinogen. Samples are then clotted at 4 gm./l. fibrinogen, 1 unit/ml. thrombin, *p*H 6·2, ionic strength 0·45, and with or without 0·001 *M* calcium chloride. Each clot is tested by addition of an equal volume of 3·0 *M* urea, giving a final urea concentration of 1·5 *M*. Of the clots containing calcium, the control samples remain unchanged, whereas the samples formed from treated fibrinogen dissolve.

Since the serum factor cannot be found in the supernatant solution resulting from an isoelectric precipitation of factor-free fibrinogen[6], it may be deduced that this procedure also results in destruction of the factor rather than separation. In agreement with this conclusion is the additional finding that isoelectric precipitation frequently fails to give factor-free fibrinogen[6]. This may simply reflect a variability in the extent of exposure to the acidic environment. This factor is thus very delicate, being destroyed by mild exposure to acid, urea or sodium bromide.

It was also discovered that the serum factor activity could be restored merely by addition of a solution of bovine serum albumin (Armour Fraction V). So little as 0·05–0·10 per cent albumin in the final clot suffices to render it insoluble in urea. It was found, however, that the addition of albumin was sometimes ineffective, and this seemed to be the result of having over-exposed the fibrinogen to the reagent. This is especially a difficulty in using the sodium bromide. It suggests either that serum factor contains two components, one of which is more stable and does not occur in the albumin fraction, or that some minor alteration finally occurs in the fibrinogen, eliminating sites where reaction with serum factor occurs.

This investigation was supported in part by research grants from the U.S. National Institutes of Health, Public Health Service.

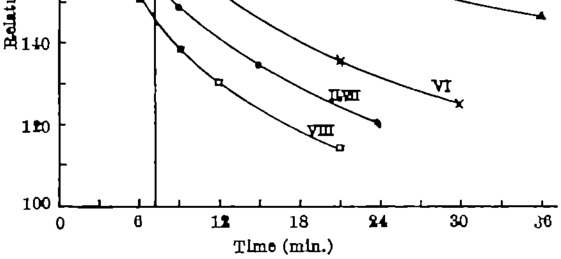
## Inhibition and Activation of Lysozyme

In a previous communication, Pantlitschko and I discussed the inhibition and activation of the hyaluronic acid – hyaluronidase system[1]. It was possible to demonstrate the inhibiting action of electronegatively charged chain molecules (heparin, sulphonated hyaluronic acid, sulphonated carboxy-cellulose, etc.) on one hand and the activating action of electropositively charged macromolecules (histone, protamine, peptone, etc.) on the depolymerization of hyaluronic acid under the influence of hyaluronidase, on the other hand. Bergamini and Ferrari[2] discussed in 1948 the inhibiting action of sulphonated macromolecules (heparin, 'Liquoid', etc.) on lysozyme activity, employing a turbidimetric method. It was thought of interest to verify the results of these authors with the much more accurate viscosimetric method developed by Meyer and Hahnel[3], and to investigate at the same time the influence of electropositively charged macromolecules.



Influence of heparin and histone on the activity of lysozyme. Substrate: carbohydrate fraction from *Micrococcus lysodeikticus* (0·2 per cent solution in water); buffer: McIlvaine (*p*H 5·8) + 0·85 per cent sodium chloride, enzyme: lysozyme (Armour, Inc.); Ostwald viscosimeter, – 37°. I, Initial viscosity (substrate with and without heparin, histone, respectively); II, normal depolymerization curve; III, heparin $1·4 \times 10^{-1}$; IV, heparin $5·0 \times 10^{-4}$, V, heparin $1·0 \times 10^{-4}$; VI, heparin $5·0 \times 10^{-5}$; VII, histone $1·0 \times 10^{-3}$, VIII, histone $1 \times 10^{-3}$

| Substance | Lysozyme | | Hyaluronidase | |
|---|---|---|---|---|
| | Inhibition (per cent) | Activation (per cent) | Inhibition (per cent) | Activation (per cent) |
| Heparin | | | | |
| $1 \cdot 4 \times 10^{-1}$ | 100·0 | — | 100·0 | — |
| $5 \cdot 0 \times 10^{-4}$ | 80·0 | — | 65·0 | — |
| $1 \cdot 0 \times 10^{-4}$ | 45·3 | — | 37·5 | — |
| $5 \cdot 0 \times 10^{-5}$ | 19·1 | — | 6·1 | — |
| Histone | | | | |
| $1 \cdot 0 \times 10^{-2}$ | — | 22·2 | — | 42·0 |
| $7 \cdot 0 \times 10^{-3}$ | — | 0 | — | 32·1 |
| $1 \cdot 0 \times 10^{-3}$ | — | 0 | — | 4·0 |

Enzyme activity was studied by the viscosimetric method described by Meyer and Hahnel[3] (see graph). Heparin inhibits lysozyme activity up to a concentration of about $5 \times 10^{-5}$. Histone, protamine and peptone are active as activators up to a concentration of about $1 \times 10^{-2}$; smaller concentrations are without influence.

When inhibition and activation are calculated by the formulæ developed earlier by us[1], a quantitative estimate is possible (see table; for comparison the respective values for hyaluronidase are also given).

It can be seen from the table that the inhibiting action of heparin on lysozyme and hyaluronidase is of the same order, though the action of lysozyme is inhibited somewhat more. The activating effect of histone and protamine on lysozyme is less pronounced. Concentrations of $1 \cdot 0 \times 10^{-3}$ and $7 \cdot 0 \times 10^{-3}$ show 4 and 32 per cent activation of action of hyaluronidase. These concentrations are without influence on the activity of lysozyme. A concentration of $1 \cdot 0 \times 10^{-2}$ histone is required to show activation of lysozyme.

We are indebted to the State of New York Department of Health (Albany) and to Prof. Favilli (Bologna) for cultures of *Micrococcus lysodeikticus*. For procuring the necessary amount of crystalline lysozyme preparation our thanks are due to Mr. Engelakind, representative in Vienna of the Armour Laboratories.

## Influence of Sulphaguanidine on the Intestinal Flora and Thiamine Synthesis brought about by Curd Feeding

Sulpha drugs bring about a marked change in the composition of fæcal flora[1]. A reduction in the number of *B. coli*, and also in their efficiency for synthesizing thiamine, have been observed by many workers[2]. We have shown that curd feeding enhanced the coliform organisms in the intestines and also the synthesis of thiamine[3]. It was therefore of interest to study the effects of sulpha drugs when administered along with curds.

Eighteen albino rats, consisting of equal numbers of males and females and weighing 80–100 gm., were fed a vitamin $B_1$-free basal diet for one week, after which period the urine and fæces of the individual rats were collected with the usual precautions and thiamine was determined[4]. The rats were then given sulphaguanidine (0·25 gm. per rat daily) along with the thiamine-free basal diet. A week later, urine and fæces were collected for three days to assess the lowering in thiamine synthesis due to sulphaguanidine feeding.

After a week's rest to overcome the effects of the sulpha drug, the rats were divided into two comparable groups; one group was given 10 γ of synthetic vitamin $B_1$ and the other 13 gm. of curd containing 5 γ vitamin $B_1$ plus 5 γ synthetic vitamin $B_1$. Three rats in each group were employed for determining the *B. coli* content of the fæces, and the other six rats were used for thiamine-excretion studies. When the rats had been on the diet for a week, urinary and fæcal collections were made. Both groups then received sulphaguanidine (0·25 gm. per rat daily), and a week later urine and fæces were collected. The *B. coli* in the fæces were also enumerated. The average values of thiamine excreted in the different cases stated above and the *B. coli* count are presented in the accompanying table.

| Period of the diet | Total daily thiamine excretion (γ) in Urine | Fæces | *B. coli* count |
|---|---|---|---|
| Basal $B_1$-free diet | 1·14 | 1·08 | — |
| Basal $B_1$-free diet + 0·25 gm. sulphaguanidine | 0·42 | 0·06 | — |
| Basal diet + 10 γ synthetic $B_1$ | 1·97 | 1·48 | $2 \cdot 8 \times 10^{8}$ |
| Basal diet + 13 gm. curd + 5 γ synthetic $B_1$ | 3·18 | 3·62 | $9 \cdot 6 \times 10^{6}$ |
| Basal diet + 10 γ synthetic $B_1$ + 0·25 gm. sulphaguanidine | 1·33 | 0·24 | $1 \cdot 5 \times 10^{8}$ |
| Basal diet + 13 gm. curd + 5 γ synthetic $B_1$ + 0·25 gm. sulphaguanidine | 2·67 | 2·76 | $6 \cdot 0 \times 10^{5}$ |

The results clearly show that with 13 gm. of curds, accounting for only 5 γ of vitamin $B_1$, the urinary and fæcal excretion of thiamine is considerably more than in the corresponding animals receiving 10 γ of synthetic vitamin. This is in conformity with our earlier findings. The reduction in thiamine excretion when sulphaguanidine is fed is much higher in the synthetic thiamine group than in the curd group. The coliform organisms in the curd group have not suffered so great a decrease as the other group, indicating that curd-feeding results in developing sulpha drug antagonism similar to that when *p*-aminobenzoic acid is administered. These observations have a fundamental and practical importance in nutrition, more especially in the case of persons who generally take curds or buttermilk with every meal.

Further work is being carried out. We desire to record our thanks to Dr. K. V. Giri for his interest in this investigation.

## Recovery of Caprinized and Lapinized Rinderpest Viruses from Condensed Water Vapour removed during Desiccation

Stein and Rogers[1] demonstrated the presence of Newcastle disease virus in the condensed water vapour removed during desiccation of material containing that virus. They failed to demonstrate the presence of vesicular stomatitis, equine encephalomyelitis, equine infectious anæmia and swine fever viruses under similar conditions.

The necessity arose for the desiccation of material containing virulent rinderpest virus in an Edwards's centrifugal freeze-dryer, normally used for desiccation of caprinized and lapinized rinderpest virus vaccines for field use. Possible contamination of the machine by virulent virus in the condensed water vapour was a factor which had to be considered. Caprinized and lapinized viruses were used to study the problem.

Spleen pulp, harvested from reacting goats, was processed in wide-mouthed tubes covered with single-layer lint sterility caps. After ten hours processing, the refrigerated coils were permitted to warm up and the condensed water vapour was collected as it drained from the exhaust valve of the condenser chamber. 5 ml. of this condensate was inoculated subcutaneously into each of four susceptible bullocks. These animals showed typical caprinized virus reactions after four to five days. One animal died on the eleventh day due to intercurrent disease. Fourteen days after inoculation the remaining animals were challenged with caprinized virus. They showed no reaction to the challenge dose whereas two susceptible controls reacted typically. The experiment was repeated with four more bullocks. Three gave typical thermal reactions while the remaining one was unaffected. On challenge, all four proved to be immune and three control animals responded thermally.

In both experiments the results indicated the presence of caprinized rinderpest virus in the condensate.

Similar results were obtained using lapinized rinderpest virus. Of six rabbits inoculated intravenously with 1 ml. of condensate, five showed the usual temperature rise within 60 hr.; the remaining one showed no reaction. Two of the reacting rabbits were killed after 96 hr. and were found to have typical lesions on post-mortem examination. After ten days the remaining four rabbits were challenged with lapinized virus. Three showed no reaction, whereas the fourth responded with a mild rise in temperature. Two control animals reacted normally. The results show that lapinized virus was present in the condensed water vapour removed during desiccation.

This work has not been repeated with virulent rinderpest virus; but it seems most probable that it could be recovered in the same manner. The necessity for collecting the condensed water vapour into disinfectant and for disinfection of the machine are apparent. It is thought that the major part of the virus in the condensate is carried over during the period of evaporative freezing when dissolved gases and water vapour are removed rapidly as indicated by the rise of condenser temperature from − 45° C. to the region of − 20° C. or higher. In this period approximately 20 per cent of the original water content is removed. Once frozen, desiccation of the material becomes considerably slower.

It has not proved possible to demonstrate the presence of either of the test viruses in material obtained by swabbing the walls of the desiccating chamber after processing.

## Indirect Determination of Water Retention in Cattle as a means of estimating Energy Exchange

The starch equivalent or net energy system, which is the basis of livestock rationing in Great Britain, measures the nutritive value of feeds in terms of the body storage of energy which occurs when they are given to fattening cattle. Only a small number of respiration chambers and calorimeters are available for work with large animals, and the expense and labour involved in their operation limit the number of experiments which can be carried out. Consequently, published values[1] are either the original ones of Kellner[2] or crude estimates based on determinations of digestibility of the feed by sheep.

An attempt has therefore been made to determine indirectly the fat storage of cattle. Protein and ash retention may be estimated by the balance method. The remaining components of a gain of weight of an animal are fat and water, and thus an accurate determination of water retention would permit an estimate of the storage of body fat. The small amount of carbohydrate stored can be ignored. In our hands, water retention could not be accurately computed from determinations of total body water by the antipyrine dilution technique[3] before and after a period of subsistence on a constant diet. Nevertheless, gross changes in the water content of the body over long periods could be estimated in this way, and the method may therefore be used for evaluating the composition of gains in body-weight of cattle at pasture.

A method has now been developed which permits the accurate estimation of water retention from the retention of sodium and potassium. Analysis of the tissues of fœtal, young and mature cattle showed that their water content could be predicted from the equation

$$\text{Water (gm.)} = 0{\cdot}2922\,\text{Na (mgm.)} + 0{\cdot}1471\,\text{K (mgm.)}.$$

This equation was obtained by the method of least squares and applied to organs, tissue fluids and fat depots, varying in water content from 99 per cent (pericardial fluid) to less than 10 per cent (fat depots of mature animals). It also applied to the whole fœtus aged three months, to amniotic fluid and to the ingesta of the rumen, small intestine and cæcum. It did not apply to the contents of the abomasum, presumably due to the high concentration of hydrogen ions. The same equation applied to the tissues of sheep and rabbits. The standard error of estimate of water content was ± 2·0 per cent. Since the equation applied to the individual tissues, it must apply to the animal as a whole and to increments in the growth of the animal, in which water retention may be estimated from the simultaneous retention of sodium and potassium.

The validity of the equation was therefore tested in experiments with growing calves, given daily rations of 1 gallon of cows' whole milk, which permitted a moderate gain of body-weight. The calves were confined in a closed-circuit respiration chamber for periods of eight days, and the storage of carbon, energy, nitrogen, water, sodium, potassium and total ash determined. The storage of water was determined directly from the water intake, the water arising in metabolism as estimated from oxygen consumption, carbon dioxide production and urinary nitrogen excretion, and the excretion of water in the fæces and urine and from the lungs and skin. Water retention was also determined indirectly from the sodium and potassium balances. The results are compared in the accompanying table.

TOTAL WATER BALANCES OF CALVES DURING PERIODS OF 8 DAYS

| Calf No. | Days | Total intake of water + metabolic water (gm.) | Water retention determined from balance of intake and excretion (gm.) | Water retention estimated from balances of sodium and potassium (gm.) | Difference (estimated less determined) (gm.) | Difference (estimated less determined) (%) |
|---|---|---|---|---|---|---|
| 167 | 1 + 2 | | 552 | 547 | −5 | |
| | 3 + 4 | | 1,136 | 1,192 | +56 | |
| | 5 + 6 | | 878 | 819 | −59 | |
| | 7 + 8 | | 439 | 683 | +244 | |
| | 1–8 | 37,459 | 3,005 | 3,241 | +236 | +7·85 |
| 168 | 1 + 2 | | 386 | 740 | +354 | |
| | 3 + 4 | | 1,217 | 644 | −573 | |
| | 5 + 6 | | 690 | 842 | +152 | |
| | 7 + 8 | | 992 | 637 | −355 | |
| | 1–8 | 38,566 | 3,285 | 2,863 | −422 | −12·85 |
| 169 | 1 + 2 | | 896 | 1,096 | +200 | |
| | 3 + 4 | | 777 | 1,040 | +263 | |
| | 5 + 6 | | 1,124 | 897 | −227 | |
| | 7 + 8 | | 730 | 811 | +81 | |
| | 1–8 | 37,747 | 3,527 | 3,844 | +317 | +8·99 |
| Complete data | | 113,772 | 9,817 | 9,948 | +131 | +1·33 |

The mean discrepancy between the two estimates of water storage for the two-day balances is ± 214 gm. water and is of the same order as that observed for the total eight-day balances. This suggests that the discrepancy arises from the aperiodicity of excretion of water and of sodium and potassium and that the percentage error attached to a gain of water would decrease linearly with length of balance period (cf. the percentage discrepancy for the complete results). There remains the further possibility of reducing the error by smoothing out, by statistical means, the daily variation in excretion of water and of sodium and potassium.

The balance method described, which is independent of the respiration chamber technique and involves only the quantitative collection of urine and fæces, should therefore permit the accurate determination of storage of protein, mineral matter and water by cattle. Since retention of water in the ingesta of the gut is simultaneously estimated by the equation, the error of an estimate of fat retention by difference from body-weight is almost entirely dependent upon the accuracy with which the animal is weighed at the beginning and at the end of the experiment. Diurnal variation in body hydration dependent upon the pattern of water intake and the periodicity of urine and fæcal excretion are important in this respect.

These experiments are being continued and extended, and will be published in detail elsewhere.

## An Action of Strongly Basic Anion-Exchange Resins and Solutions containing Sugars

In view of the expanding use of strongly basic ion-exchange resins in the isolation of plant acids[1,2], a recent experience in this laboratory emphasizes a need for caution in the application of such techniques.

Paper chromatograms, prepared from certain 'acid fractions' of extracts of immature apple fruits, run in butanol – formic acid – water (40 : 10 : 50 v/v), and sprayed with suitable indicator solutions, gave spots for several 'unknown' acids ($R_F$ 0·24, 0·29, 0·43, 0·50, 0·67, 0·81), the largest spot being at $R_F$ 0·67. The acid responsible for this spot was eventually identified as lactic acid. The 'acid fractions' had been prepared by passing an extract of the fruit, obtained as previously described[3], and freed from amino-acids but containing all the sugars of the fruit, down a column of 'Dowex 2' to absorb the acids, and then fractionally displacing them by means of 0·1 *N* hydrochloric acid.

The apparent isolation of appreciable amounts of lactic acid from fruit which before death had free access to oxygen was surprising, especially since no comparable amounts of pyruvic or other acids associated in metabolism with lactic acid were noted. It was found that if the acids of the apple were isolated by adsorption on, and displacement from, weakly basic resins such as 'Deacidite *E*', no lactic acid appeared.

It is well known that lactic acid is produced when sugars are treated with alkali, and it appeared possible that some at least of the lactic acid obtained arose from the action of the basic 'Dowex 2' resin on the sugars present in the apple extract as they passed down the column. A somewhat analogous case, the hydrolysis of glycosides and disaccharides by strongly acid resins, was studied by Wadham[4]. To test this hypothesis, a solution was made containing glucose, fructose, sucrose, malic acid and quinic acid in roughly the proportions present (6 per cent sugar and 1 per cent total acid) in the amino-acid free apple extracts. This solution was passed down a 'Dowex 2' column and treated in the same way as the apple extracts mentioned earlier. Paper chromatograms were prepared (run in both butanol – formic acid – water, and propanol – ammonia – water, 60 : 30 : 10 v/v) from the original solution and, after concentration to a small volume, from the various fractions displaced from the 'Dowex 2' column with 0·1 *N* hydrochloric acid. In all the first fractions from the column, clear evidence of lactic acid was obtained.

From a comparison of the size of the spots on the various chromatograms, it is certain that at least the greater part of the lactic acid apparently obtained from the apple was an artefact produced from the sugars present. A little may perhaps have been present in the original extract. Bryant and Overell[1], using the strongly basic resin 'Amberlite IRA 400', obtained traces of an 'unknown' acid from the juice of apples and carrots which had an $R_F$ in butanol – acetic acid – water similar to that of our lactic acid spots. They, however, used the resin in the less-alkaline carbonate form. In our experiments, in which a solution of sugars and acids similar to the one mentioned earlier was passed down 'Amberlite IRA 400 (OH)' in the carbonate form instead of 'Dowex 2', no sign of lactic acid was observed. It appears, therefore, that acids may be adsorbed with safety from plant extracts rich in sugars by strongly basic resins in the carbonate form. In this form, however, the resins have a low capacity, and the concentration of the acid in the solutions passing down them must be very low to prevent evolution of carbon dioxide, with subsequent break-up of the column.

For the separation and isolation of small amounts of acids in the presence of large amounts of other acids, it appears preferable to separate the acids *in toto* from the sugars by a preliminary adsorption on weakly basic ion-exchangers followed by displacement; followed by fractionation on strongly basic anion-exchangers in the 'hydroxyl' form in which they have their highest capacity and resolving power (because of 'tighter' bands) for acids.

The work described in this paper was carried out as part of the programme of the Food Investigation Organization of the Department of Scientific and Industrial Research.

## Percentage of Binucleate Cells in the Livers of Adult Rats

SEVERAL workers have suggested that the percentage of binucleate cells seen in histological sections is not a true measure of the percentage of such cells in the liver. The cells of the liver are so large, varying between 12 and 25 μ in diameter, that a considerable number of the cells in a section 6–8 μ thick must have been cut through, and in some cases two nuclei may have been separated. Pfuhl[1] corrected for this error in counts made on the livers of rabbits by assuming that the percentages of binucleate cells in sections 5 and 7·5 μ thick were one-third and one-half the absolute value, respectively. Later, Müller[2] elaborated a formula for converting the observed counts to the real percentages. It would be preferable to count the binucleate cells in a suspension of liver cells; but the difficulty has been to prepare a suitable suspension. Recently, Bucher and Glinos[3] reported finding three times as many binucleate cells in a cell suspension as in a section 6–8 μ thick. This suspension had been prepared by agitation of tissue slices in saline (private communication by Dr. N. Bucher).

A simpler method for preparing a cell suspension has now been developed and was used for counting the binucleate cells in the livers of adult male and female hooded rats of the Lister strain. A sample of fresh liver was homogenized for one minute at a low speed in the machine described by Folley and Watson[4] with ten times its volume of the medium described by Robinson[5]. A drop of the suspension so obtained was then mounted and stained with toluidine blue, and the number of binucleate cells in at least 1,000 cells counted. Duplicate counts varied by less than 1 per cent, that is, by less than 3 per cent of their actual value. The results have been listed in the accompanying table together with values for the percentage of binucleate cells in histological sections of livers from rats of similar weight, age and strain. These sections were kindly prepared by Dr. A. M. Barrett, Department of Pathology, Cambridge.

PERCENTAGE OF BINUCLEATE CELLS IN THE LIVERS OF ADULT MALE AND FEMALE RATS

| Sex | Counts made on | | | |
|---|---|---|---|---|
| | (a) Cell suspension | | (b) Histological section | |
| | Weight of rat (gm.) | Binucleate cells (per cent) | Weight of rat (gm.) | Binucleate cells (per cent) |
| Male | 270 | 32 | 267 | 10 |
| | 266 | 30 | 273 | 11 |
| | 268 | 29 | | |
| | 290 | 29 | | |
| Female | 202 | 29 | 200 | 11 |
| | 220 | 29 | 216 | 12 |
| | 235 | 29 | | |
| | 200 | 31 | | |

Some cells were inevitably fractured in the preparation of the suspensions, but these formed only a small proportion of the liver cells, for drops of the suspensions contained mostly intact cells and remarkably little debris. The cells remained intact and separate for at least seven days when the suspensions were stored at 0–2° C. It seems reasonable, therefore, to assume that the mononucleate and binucleate cells had been broken in the same proportion in which they occurred in the liver.

Between 10 and 12 per cent of the cells in histological sections of the livers of both sexes appeared binucleate, in agreement with values reported by earlier workers. It was obvious that many of the cells in the sections had been cut, for all the lobules contained many 'cells' without any nuclei at all. Even though these non-nucleated 'cells' were not included in the counts, the proportion of binucleate cells in the sections was only one-third of that in the cell suspensions. There was no difference between the percentages of binucleate cells in the livers of adult male and female rats: and despite variations in the weights of the rats these values were almost constant at 30 per cent. This figure was required as a step in calculating the chemical composition of the average liver cell[6]; but its agreement with that found by Bucher and Glinos[3] for albino rats is worth recording.

## Composition of Whales' Milk

It has been possible to obtain eight samples of whales' milk for analysis through the very willing co-operation and help of Dr. E. Downing and Mr. J. A. B. Athey, of Chr. Salvesen and Co., Leith, and Dr. J. G. Sharp, of the Low Temperature Research Station, Cambridge. Two of the samples were from blue whales (*Balaenoptera musculus*) and the remainder from fin whales (*Balaenoptera physalus*). The milks were collected after dissection of the mammary glands during the flensing operation on board Salvesen and Co.'s factory ships *Southern Venturer* and *Southern Harvester* engaged in pelagic whaling in the Antarctic. The period between the death of the whales and the collection of the milk varied from 6 hr. for sample 7 to 19 hr. for sample 4. The samples were stored in glass bottles at a temperature of − 20° C. while on board ship and ashore, before being conveyed to the Hannah Institute with as little rise in temperature as possible. At the Hannah Institute the samples were kept at 4° C. and analysed without delay. Samples 1–3 were at a temperature of − 20° C. for six to seven months and samples 4–8 for two to three months.

It should be noted that the killing of lactating whales, that is, those accompanied by a calf, is illegal and that the samples discussed here were obtained from whales accidentally separated from their calves during the chase or, much more likely, from whales whose young had finished weaning and left their dam. It therefore seems probable, as the data of Mackintosh and Wheeler[4] would also suggest, that the majority of lactating whales caught during the antarctic whaling season (late December – early March) are in the last stages of lactation or in the process of drying-off. Thus the composition of the eight samples obtained may not be typical of normal whale milk; on the other hand, one of Salvesen and Co.'s chemists who has experience of the time when no restrictions on killing were in force, informed me that the percentage of fat in the milk from a whale actively feeding a calf was about 39 per cent—a value similar to the fat content of five of the present samples. Over the four seasons, 1948–49, 1949–50, 1950–51 and 1951–52, the combined catch of the *Southern Venturer* and the *Southern Harvester* was 16,000–17,000 whales, of which only twenty four were lactating.

Composition of Whales' Milk

| Species of whale | Length (ft.) | Date caught | gm./100 gm. milk | | | | | |
|---|---|---|---|---|---|---|---|---|
| | | | Water | Fat | Protein (N × 6·38) | Ash | Lactose (by diff.) | Lactose (detd.) |
| 1. Blue | 83 | 24.2.49 | 45·7 | 40·0 | 12·0 | 1·2 | 1·1 | — |
| 2. Blue | — | 10.3.49 | 48·6 | 39·1 | 11·3 | 1·5 | — | — |
| 3. Fin | 75 | 27.2.49 | 48·1 | 39·7 | 11·3 | 1·3 | — | — |
| 4. Fin | 77 | 5.1.52 | 61·8 | 18·5 | 13·1 | 1·8 | 4·8 | 4·5 |
| 5. Fin | — | 14.1.52 | 76·2 | 17·1 | 3·6 | 0·8 | 2·3 | 0·7 |

| 7. Fin | 68 | 8.2.52 | 45·0 | 37·8 | 12·1 | 1·4 | 3·7 | 3·6 |
| 8. Fin | 69 | 22.2.52 | 50·0 | 37·8 | 10·2 | 0·8 | 1·2 | 1·0 |
| Average composition of milk from Ayrshire cows | | | 87·2 | 4·0 | 3·3 | 0·9* | — | 4·6 |

* By difference; includes approximately 0·2 per cent citrate

The milks were white or very pale cream in colour, had a slight fish-like odour reminiscent of cooked cod-roe and a consistency of thick cream at laboratory temperature; sample 5 had a thinner consistency and sample 4 was very slightly contaminated with blood from an external source. The samples were analysed by the methods usually employed for ordinary milk or concentrated milk products, with small modifications where necessary. The reducing sugar determined in samples 4–8 by a chloramine-*T* potassium iodide oxidation method was assumed to be lactose and was calculated as the anhydrous form. The sugar content of samples 4–7 was determined by Mr. Athey on board the *Southern Harvester* by the same analytical method. His results were not identical with those obtained under the much more favourable conditions at the Hannah Institute, but they suggest that no serious decomposition of lactose occurred during storage, except perhaps in sample 5.

The results in the accompanying table show that whales' milk is much richer in fat and protein and contains less lactose than cows' milk. In these respects, it is similar to the milk of the other cetaceans, the dolphins[1] and the porpoises[2], and also to seals' milk[3]. Rich milk of this type seems to be characteristic of mammals which live in a cold environment and whose young have a rapid rate of growth. The composition of the milk of the two species of whale is very similar; the differences among the samples are probably compounded of lactational effects, individuality and sampling errors, the lactational effects probably being of greatest importance.

With the help of Dr. F. C. Fraser of the British Museum (Natural History) a list of references to literature on the composition of whales' milk has been compiled. None of these reports gives as complete an analysis on as many samples as the present investigation. In general, the results in these publications for milk of several species of whale, including blue and fin whales, are similar to those presented here. Two of the most recent of these reports on whales' milk are by Rowland[5], who analysed three samples of milk from blue whales, and by Pedersen[6], who gives the composition of milk from a humpback whale (*Megaptera nodosa*).

This investigation will be reported in more detail elsewhere, when an account of some minor constituents of whales' milk will be given together with a review of the literature on the milk of this very valuable and largest mammal.

I am much indebted to Chr. Salvesen and Co. and Dr. Downing for the information they have given me about whaling.

## Silver Impregnation of Nerve Fibres

THEORIES of the mechanism of staining of nerve fibres by impregnation with silver solutions have at various times been based on adsorption, and on the stoichiometric combination of the silver and the protein. It seems most probable in the light of recent work on protein – metal complexes[1] that the combination is stoichiometric, and the following investigation appears to support this view.

Spinal cord and sciatic nerve from the frog were fixed in 70 per cent alcohol for three days and then embedded in paraffin wax; sections were impregnated on the slide in a 1/20,000 silver nitrate solution at 37° C. After impregnation the slides were washed for 5 min. in three changes of distilled water to remove any uncombined silver and were then reduced in sodium sulphite – hydroquinone reducer according to the method of Holmes[2].

When the impregnation was carried out for 17 hr. in silver nitrate solution buffered over the range $p$H 4·0–9·0, it was found that very little silver was taken up below $p$H 7; but above this value the amount increased rapidly to $p$H 9. Since free carboxyl groups are fully ionized at $p$H 6, this suggests that such groups are not the sites of combination of the silver, but rather that some 'weak' grouping is responsible. Even at $p$H 9, silver uptake is small for less than 1¼ hr. impregnation, increasing most rapidly between 1½ and 2 hr. This slow reaction also indicates that the combination is due to some weak grouping or to the formation of silver complexes. Any reaction with amino or carboxyl groups would be relatively rapid, as in staining methods using acidic or basic dyes. Attempts were made to block end-groupings in the proteins by using some of the reagents suggested by Danielli[3] and Olcott and Fraenkel-Conrat[4]. The results are indicated in the accompanying table, showing the extent to which the silver impregnation was specific to the nerve fibres and the general level of intensity of the stain at $p$H 9.

| | Specificity to the nerve fibre | Intensity of impregnation |
|---|---|---|
| Control | ++ | ++ |
| *Amino groups* | | |
| Nitrous acid | ++ | + |
| Formaldehyde | ++ | ++ |
| Picric acid | ++ | ++ |
| Iodoacetic acid | ++ | ++ |
| *Carboxyl groups* | | |
| Esterification (MeOH+HCl) | + | ++ |
| Diazo-methane (in ether) | 0 | + |
| *Sulphydryl groups* | | |
| Iodoacetic acid | ++ | ++ |
| Hydrogen peroxide | ++ | + |
| Periodic acid | ++ | ++ |
| Performic acid | + | 0(+) |
| *Disulphide linkages* | | |
| Thioglycollic acid followed by iodoacetic acid | ++ | ++ |

Though it would thus appear that carboxyl groups play some part in the silvering process, the slow reaction and incomplete loss of specificity suggest that they are not the actual sites of silver uptake. The possibility of a reaction with aldehyde groupings can be eliminated, since these are not present in alcohol-fixed material[5]; the Feulgen test is, in fact, negative. Extraction of nucleic acids with trichloracetic acid[6] did not affect the impregnation. There remain to be considered the ring-containing amino-acids, tryptophane, tyrosine and histidine.

The specificity of performic acid as a blocking agent for tryptophane (as well as for sulphydryl groups) is useless, as the reagent employed contained a considerable amount of formic acid, which itself greatly reduces the intensity of the impregnation for some reason not known. Of the other two possible reagents, benzoyl chloride and 2.4-dinitrofluorobenzene both greatly reduce staining; the former 'blocks' tryptophane, tyrosine and histidine, the latter blocks tyrosine and to some extent histidine[7]. The fact that staining begins as low as $p$H 7 suggests the combination of silver with the —NH groups of histidine, which has a $p$K value of 6–7 (the $p$K of tyrosine is 10). Silver impregnation of smears of the four proteins

haemoglobin > fibrinogen > pepsin > protamine

showed a descending order of intensity of impregnation. This order parallels that of their histidine content[8] but not of their tyrosine content.

These results suggest that the silver impregnation of nerve fibres is due chiefly to the combination of histidine groups with the metal and confirms the recent work of Grassman and Kursch[9]. These authors conclude that at $p$H 6·2 the amount of silver combined with proteins of the collagen type is proportional to the histidine content.

I wish to thank Profs. J. E. Harris and J. F. Danielli for their criticism and advice.

## Association of Glucose, Arabinose and Xylose in Jute

THE nature of the association between glucose, xylose and arabinose in the plant is extremely complex. Although a considerable amount of work on glucoxylan or cellulosan[1–7] and xyloaraban or araboxylan[8,9] has been done, the nature of their association has not been definitely established. In some quarters it is believed that the nature of the association between glucose and xylose in the plant might be that of a solid solution type or of mixed crystals[5]. Schmidt[3], Norman[4] and others suggest a chemical combination between glucose and xylose or the presence of cellulosan in the cellulosic materials, whereas Sarkar, Mazumdar and Pal[7] conclude that there is no cellulosan in jute. The present general belief[10] is that association between xylose and glucose is more of a physical than of a chemical nature.

The presence of cellulosan in the plant could not be definitely established due to the failure to isolate simple oligo-saccharides containing glucose and xylose or glucose and arabinose. This seems to be due to the fact that selective hydrolysis had not been tried. Recently, Das, Chaudhuri and Wareham[11] have therefore used a weak acid under controlled conditions for hydrolysis of jute holocellulose. This work has been extended by us[12] in hydrolysing the so-called jute α-cellulose, where it has been definitely shown, in contradiction to the finding of Sarkar *et al.*, that α-cellulose invariably contains xylose and that even by fractional hydrolysis pentose-free α-cellulose could not be obtained. Later on, it was found by us that arabinose is also present in jute α-cellulose together with xylose irrespective of the methods of its preparation and even when the last trace of lignin is removed by Norman and Jenkins's method[13].

Like xylose, arabinose also could not be separated from lignin-free α-cellulose even by fractional hydrolysis[12]. This seems to indicate the presence of cellulosan in jute and that the arabinose might be present in pyranose form. This finding, again, cannot be taken as conclusive in establishing the theory of cellulosan, since it is possible that xylan or araban are separate units and that the portion of α-cellulose which was accessible to formic acid was only hydrolysed, so that the association between cellulose and pentosan is only a question of their physical environment rather than chemical union. This is specially so, as it has been shown by Das, Chaudhuri and Wareham[11] by the paper chromatographic method that, in the first hydrolysate (fraction 1) of jute holocellulose, most of the pentosan is hydrolysed but no hexosan.

In order to resolve these conflicting views it was essential, therefore, to follow selective hydrolysis of so-called α-cellulose with formic acid so as to obtain simple oligo-saccharides on the hydrolysate and to identify by paper chromatography the gluco-xylose or gluco-arabinose linkages. For this purpose 1·5 gm. α-cellulose, prepared by treating chlorite jute holocellulose with 17·5 per cent caustic soda as recommended by the American Chemical Society method and modified by Sarkar[14], was hydrolysed with 30 c.c. formic acid (85 per cent) for twelve minutes at 135° C. and the hydrolysate was filtered, made free from acid and decolorized in the same way as done previously[11]. The neutral clear solution was then chromatographed with moist phenol and moist butanol as solvents. Besides the spots of xylose, glucose and arabinose which were isolated and identified in the same way as explained previously, in the case of holocellulose[11] the presence of a new prominent spot in between the spots of uronic acid and glucose has been detected which, however, disappears if the hydrolysis is continued for another three hours. This new complex sugar gives a brownish-pink colour with aniline oxalate spray which is quite distinguishable from the pink colour of xylose and arabinose or the yellow to brown colour of glucose, and travels much slower than maltose but just a little slower than xylotriose. This indicates that the new complex is most probably a triose or tetrose. In order to isolate this complex, the concentrated hydrolysate of jute α-cellulose was chromatographed on Whatman No. 1 filter paper with moist phenol as solvent for ninety hours and the band corresponding to the new spot was cut off. This strip was then extracted with water and evaporated under low temperature and pressure to a small volume. The complex gave only one spot and no trace of any other sugar was obtained even when the chromatograph was run for seventy hours. This was then hydrolysed again for one hour with 85 per cent formic acid at 135° C., the hydrolysate made free from acid, then chromatographed, which shows the spot of the original new complex sugar due to the incomplete hydrolysis and the spots of glucose, xylose and arabinose. The last three sugars were isolated and identified in a similar manner, as explained earlier. It is noticeable that while the parent substance is brownish-pink in colour, its components xylose and arabinose are very bright pink, whereas glucose is only faint yellow, when developed by aniline oxalate reagent.

The above finding conclusively proves the presence of cellulosan, or chemical union between α-cellulose and pentosans. It may be in the form of glucose–xylose–arabinose, glucose–arabinose–xylose or xylose–glucose–arabinose. The above results also suggest a union between xylose and arabinose either with each other or through glucose. This simple oligo-saccharide containing arabinose, xylose and glucose could not be isolated by previous workers probably due to the fact that arabinose generally exists in Nature in furanose form, whereas in this case arabinose seems to be present in pyranose form. Detailed work will be published elsewhere.

Thanks are due to the directors, Jardine Henderson, Ltd., for their permission to publish the results, and Dr. S. K. Chanda for the gift of xylotriose.

## A New Photoperiodic Phenomenon in Short-Day Plants

THE classical researches of Hamner[1] on photoperiodism indicated that the flowering of short-day plants, such as Biloxi soybean, is dependent upon exposure to a certain minimum ('critical') dark period. Within certain limits, the length of the critical dark period is largely independent of the duration of the light period, but when the latter reaches 20 hr., flowering in Biloxi soybean will not occur even if the associated dark periods exceed the critical value. The possibility that the length of this limiting light period may vary with the duration of the dark period has apparently never been investigated.

During the course of some recent photoperiodic experiments, it was found that plants of 'Biloxi' soybean flowered when exposed to ten cycles in which the dark periods were of 22 hr. and the light periods of 8 hr. duration, but did not flower when the cycles included 22 hr. of dark and 14 hr. of light. In another experiment with the short-day species *Perilla*

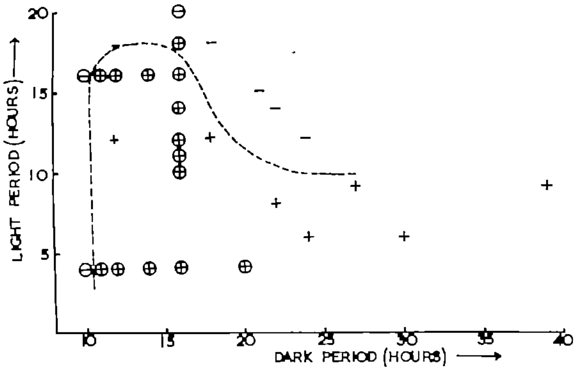
| Photoperiod (hr.) | Dark period (hr ) | Number of plants | | Mean number of flowering nodes per plant |
|---|---|---|---|---|
| | | Flowering | Vegetative | |
| 6 | 24 | 7 | 0 | 7 3 |
| 6 | 30 | 4 | 3 | 2 6 |
| 6 | 42 | –* | –* | —* |
| 9 | 27 | 6 | 0 | 4 2 |
| 9 | 39 | 7 | 0 | 5 9 |
| 12 | 12 | 9 | 0 | 12 8 |
| 12 | 18 | 6 | 3 | 1 1 |
| 12 | 24 | 0 | 8 | 0 |
| 15 | 21 | 0 | 8 | 0 |
| 18 | 12 | 0 | 9 | 0 |
| 18 | 18 | 0 | 8 | 0 |

* Plants died

*ocymoides*, it was found that flowering occurred with cycles of 6 hr. light and 30 hr. dark, but not with 12 hr. light and 24 hr. dark. These results suggested that, when the dark period is abnormally long, the length of the associated light periods must be reduced if flowering is to occur.

The following further experiment was carried out with Biloxi soybean in order to investigate this effect in greater detail. All plants were grown under 'long days' until the third trifoliate leaf was expanding and were then exposed to one of eleven different photoperiodic regimes, in which various lengths of dark period ranging from 12 to 39 hr. were used in conjunction with light periods ranging from 6 to 18 hr. (see table). The treatments were carried out in 'growth cabinets' in which lighting was provided by 'daylight' fluorescent lamps giving an intensity of approximately 1,000 foot-candles. The temperature during both the light and dark periods was thermostatically controlled at 21° C. Each treatment was continued for ten cycles, after which the plants were returned to long-day conditions for 16–18 days, when the plants were dissected for observation of flower-initiation. In those groups in which the light periods were of only 6 or 9 hr. duration, a few plants became moribund following the treatment and had to be discarded.

The results are summarized in the table. Maximum flowering occurred with a cycle of 12 hr. light and 12 hr. dark. The flowering response was reduced in all treatments in which the dark period was prolonged beyond 12 hr.; but this effect was much more marked in treatments in which photoperiods of 12 hr. or more were used, and indeed flowering was completely inhibited when light periods of 15 and 12 hr. were used in conjunction with dark periods of 21 and 24 hr. respectively.



Effect of duration of light and dark periods on flowering of Biloxi soybean
+ = flowering. – = not flowering Points from Hamner's results (ref. 1) enclosed in circles. In drawing the curve, consideration has been given to the magnitude of the positive flowering responses

The accompanying graph has been prepared from the results of the present experiments and from those of Hamner. A curve has been drawn to indicate what appear to be the limiting lengths of light and dark periods for flowering. From this curve it is seen that when the dark period exceeds 12 hr., the duration of the limiting light period falls rapidly to approximately 10 hr. with a dark period of 27 hr. Further extension of the dark period to 39 hr. leads to no further fall in the duration of the limiting light period, however.

The preliminary results obtained with *Perilla ocymoides* described above suggest that a similar effect will be found in that species. Moreover, there is some evidence from the results given by Schmitz[2] that the limiting light period falls in *Kalanchoe blossfeldiana* with a dark period of 32 hr.

An analogous result (though in the reverse sense) was obtained by Claes and Lang[3] with the long-day plant *Hyoscyamus niger*. When this species is grown on a 24-hr. cycle, flowering will only occur if the light period exceeds 10 hr.; but on a 48-hr. cycle, light periods of 9 and 10 hr. are effective in promoting flowering. Thus it appears that the effect observed in soybeans may occur in both short-day and long-day plants.

It is somewhat surprising that this important phenomenon seems to have escaped observation, due apparently to the fact that in past experiments either the dark periods used were not sufficiently long or the accompanying photoperiods were relatively short and did not attain the limiting value. In this connexion, we may note that the duration of dark period necessary to reveal the phenomenon is, in any event, apparently greater in Peking soybean[4] and *Kalanchoe blossfeldiana*[2] than in Biloxi soybean.

## Saprophytic *Cladosporium* in Britain

It has been generally accepted that all the *Cladosporium* which occurs saprophytically in Britain belongs to the ubiquitous species *C. herbarum*. Brooks and Hansford[1] examined many isolates of *Cladosporium* from dead materials and concluded that they were all *C. herbarum*. The list of British Hyphomycetes[2] contains twenty-six names of species of this genus; but Bisby[3] considers the records of only four of these to be valid for Britain, namely, three parasites, *C. paeonia*, *C. fulvum* and *C. cucumerinum*; and one saprophyte, *C. herbarum*.

In investigations of airborne mould spores at this Unit, two distinct types of *Cladosporium* have appeared regularly on Petri dishes exposed to the outside air. Type *A* had branched chains of mainly small spores about 3–7 µ by 3–5 µ, oval or globose, with some larger but more elongate near the conidiophore. The small spores were mainly one-celled and the larger ones frequently two- or more celled. The spore walls were normally smooth. The macroscopic appearance of these colonies showed considerable variation in texture, colour and amount of sporing, etc., as described by Brooks and Hansford. These colonies were considered to be typical *C. herbarum*.

Type *B* produced large verrucose, oblong spores, mainly 13–19 μ by 7–8 μ, in short branched chains of usually three to five spores. The branches frequently consisted of one or two spores only. About 50 per cent or more of the spores were one-celled and the remainder two-celled, with a small proportion more than two-celled. The colonies were nearly always more woolly than the woolly variants of Type *A*, and the overgrowth of sterile hyphæ was white-grey rather than olive in colour. The features of this mould could not be reconciled with the description of any British species of *Cladosporium*.

The distinction between these two types had previously been noticed by Hyde and Williams (personal communication) in their studies on air-borne spores at Llandough Hospital[4]. Through the help of Dr. M. B. Ellis, a culture was examined by Dr. G. A. de Vries at the Centralbureau voor Schimmelcultures, Holland, and identified as *C. macrocarpum* Preuss. This species is recorded by Saccardo[5] from moribund plants in France, Germany and Italy.

On the Petri dishes of Sabouraud's agar exposed daily in this Hospital in a shelter of the Hyde and Williams pattern[6], *C. macrocarpum* is rarely observed during the months October to April, but considerable numbers are seen on the plates during June, July and August. During these months also, about 75 per cent of the whole year's catch of *C. herbarum* appears on our plates. During 1951 from a pair of plates exposed every week-day, 3,047 colonies of *Cladosporium* were counted. Of these, 364 (12 per cent) were *C. macrocarpum* and the remainder *C. herbarum*.

Hyde and Williams find that at Llandough in 1950 the large-spored *Cladosporium* formed about 12 per cent of their total catch of *Cladosporium* (to be published).

In a current investigation, collaborators are exposing Petri dishes of Sabouraud's agar daily at Cambridge, Edinburgh, Llandough, Southampton, London and Liverpool in parallel with our exposures at Cardiff, and returning them to Cardiff for examination. *C. macrocarpum* has appeared on plates from all these places. Dr. P. H. Gregory and Mr. Edward Yuill, carrying out a parallel series of exposures at Rothamsted (Harpenden) and Acomb (York), respectively, have both observed this species on their plates. In view of its widespread and abundant occurrence in Great Britain, it is surprising that there appears to be no previous record of *C. macrocarpum* in the British literature.

These investigations were pursued during my tenure of a full-time research grant from the Asthma Research Council.

## Randomly Stacked Layers in Clay Minerals

CLAY minerals having a lamellar structure commonly show a particular type of random stacking, in which only a limited number of definite interlayer spacings exist, but these are distributed with various degrees of randomness. Examples are: mica of 10 A. spacing, with a certain proportion of 14 A. hydrated layers; glycerol-saturated montmorillonite (17·7 A.) in which a certain proportion of layers of lower glycerol content (14 A.) is present; partly dehydrated halloysite[1] (mixture of 10·0 A. and 7·2 A. layers).

It is desirable in such cases to have a means of determining which spacings are present in the mixture, and in what proportions. Formulæ have been derived, enabling the scattering given by random, and partly random, mixtures to be calculated[2]. It is possible, using these, to make a set of curves showing the type of scattering to be expected from various mixtures likely to be met with in practice[3], and these can be used for identifying such mixtures when they occur. However, with mixtures of more than two components, and those which are not completely random but show various degrees of segregation, this method requires the calculation of a very large number of curves. It is therefore very desirable to have a direct method of getting the required information from the measured data.

It has been pointed out by Méring[4] that in principle the Fourier transform of the diffraction diagram gives this information. The transform is difficult to calculate in practice because the totality of the diffraction diagram is not available for study. Generally, the low-intensity regions are masked by the background, and quite often the whole diagram is complicated by the presence of accessory lines, from the same or from different minerals (it is to be remembered that only the part of the diagram arising from the basal reflexions is of interest).

Examination of calculated diffraction curves for mixtures (and of actual diffraction diagrams) shows that the diffraction from such mixtures commonly consists of relatively sharp lines, which, however, do not form an integral series of orders. The information readily available consists of the effective spacings and intensities of these lines. It is possible to show that a Fourier transform may be calculated, using only these data, which will, in general, give the required information. The cosine transform

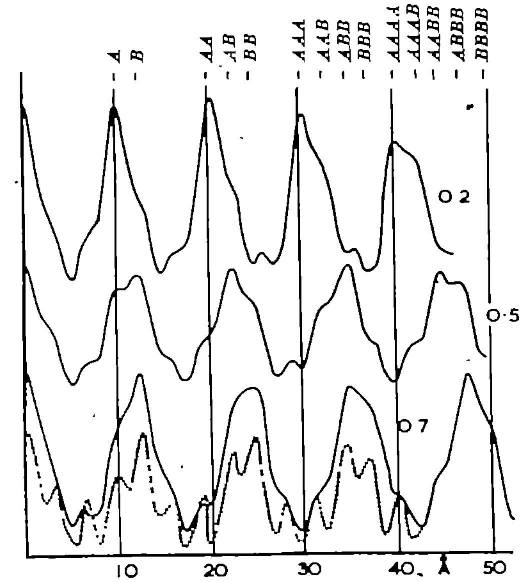
$$\int_0^\infty \frac{I(\mu)}{\Theta\,|F_l|^2} \cos 2\pi\mu R\,d\mu$$

is a function which is proportional to the mean number of layers at a distance $R$ from any arbitrary layer chosen as origin. Here $\mu$ is reciprocal spacing. $\Theta$ the Lorentz-polarization factor and $F_l$ the scattering factor of a single layer (all the layers are supposed to be the same, and the scattering by the interlamellar material is supposed to be small). This form of function, which gives a peak at the origin, is more convenient to use than the transform of $\frac{I(\mu)}{\Theta\,|F_l|^2} - 1$ (James[5], p. 478), which requires a knowledge of absolute intensities.

In the case of a diagram composed of isolated, fairly sharp peaks with reciprocal spacing $\mu_r$ and integrated intensity $I_r$, we may approximate to the above transform by the sum :

$$\Sigma_r \frac{I_r}{\theta\,|F_l|^2} \cos 2\pi\mu_r R.$$

This sum makes use only of the observable data ($I_r$ and $\mu_r$), and has a number of terms equal to the number of lines, and therefore not usually more than ten or so. It seems in general (even when some of the lines are rather broad) to give a very good idea of the composition of a mixture. A test of this is to use the peak positions and intensities calculated by G. Brown and myself[3] for a series of random structures and to calculate the above series for them. The accompanying diagram shows the result for three random mixtures of 10- and 12·4- A. spacings with mica-type layers. The actual value of the spacings and their proportions are well shown, and it is possible from the 'combination peaks' of spacing greater than 12·4 A. to obtain an idea of the degree of randomness of the mixture : the method, which is relatively straightforward, cannot be discussed in detail here.



Calculated series for mixtures of 10 A. and 12·4 A. spacings with mica-type layers. The number attached to each curve gives the proportion of the higher spacing The ordinates of these curves are proportional to the probability of finding a layer at a given distance from any layer chosen as origin : the (arbitrary) zero level is not shown. The letters indicate the significance of the peaks, *A* meaning a 10 A. spacing, and *B* a 12·4 A. spacing; thus *AAB* is a peak which arises from two spacings of the first type plus one of the second (in any order). The meaning of the dotted curve is explained in the text

The series shown were calculated using only three lines. For such a series diffraction effects may give rise to spurious peaks. These series were therefore calculated after artificially diminishing the high-order terms, and the resulting 'smoothed' series, although not showing spurious peaks to any considerable extent, tends to confuse neighbouring peaks so as to make it difficult to determine the actual spacings present. These can, however, be accurately determined by calculating an 'unsmoothed' series as well ; by comparison with the 'smoothed' series the spurious peaks can be readily detected, and the spacings of the genuine peaks measured accurately. The dotted curve in the diagram shows an 'unsmoothed' series corresponding to the lower 'smoothed' curve, and will serve to illustrate the afore-mentioned points.

## Multiple Bursts of Signal in Long-Distance Very-High-Frequency Propagation

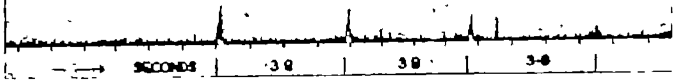
DURING the course of recent investigations into the behaviour of radio wave propagation within the 40–60 Mc./s. television band, new phenomena have been observed. For these investigations use has been made, during normal programme hours, of the continuous wave transmission from the B.B.C. television station at Kirk-o-Shotts operating on a frequency of 53·25 Mc./s. (sound), at a distance of 330 miles from the observing station at Great Baddow, Essex.

Normally, a continuous signal of slowly varying amplitude is observed having a mean value of 20 db. below 1 μV./m. but well above narrow-band receiver noise. Superimposed upon this signal is a succession of signal bursts of between 0·1 and 1·0 sec. duration with amplitudes up to 30 db. greater than the mean level of continuous signal ; the frequency of occurrence of these bursts varies from about 3 to 20 per min.

Many of these bursts exhibit characteristic Doppler frequency shifts and are identified with meteors and their trails ; but among the remaining bursts are many examples of a clearly related pair having a time separation varying from 0·7 to more than 6 sec., this time separation being constant for many pairs over periods of observation of about 15 min. Furthermore, trains of three and four bursts having a constant time separation have also been recorded ; the accompanying record shows one such quadruple train, having a time separation of approximately 3·8 sec., in which the bursts occur in descending order of magnitude.

The greatest frequency of occurrence of multiple trains was during the thunderstorm of October 24, 1952, when clear evidence was recorded that separate bursts and pairs of bursts frequently followed a lightning flash. At no time has there been any evidence that succeeding bursts in a train are in any way echoes of the first. Considering that the transmitted signal is an uninterrupted continuous wave, it is suggested, therefore, that the mechanism causing multiple bursts is a relatively local recurrent condition of the medium consequent upon a lightning flash.

It is interesting to recall that T. L. Eckersley has described[1] a peculiar class of atmospheric which he terms a 'whistler'. These whistlers, received by means of a long aerial and an audio-frequency amplifier, are preceded by a click which has since been identified



with a lightning flash. Eckersley furthermore describes trains of whistlers having a time separation of about 3·8 sec. between each succeeding whistler. It seems probable, therefore, that the phenomena of multiple signal bursts and whistlers are closely associated.

A more detailed account of these observations will be published later.

## A Theoretical Model for Arches in the Solar Corona

IN recent years, the belief has grown among solar physicists that magnetic fields play an essential part in the phenomena of solar prominences. The study of the static equilibrium of an ionized atmosphere in a gravitational field with some magnetic field also present is expected to shed light on the more difficult dynamical problems, but may also provide models for quiescent prominences, which appear to be almost in static equilibrium. The condition for static equilibrium is that the resultant of the pressure gradient and the gravitational and electromagnetic force densities should vanish.

The simple model has been studied in which (i) the temperature and composition of the atmosphere are uniform; (ii) the gravitational field is uniform, the $z$-axis pointing upwards; and (iii) the magnetic field is two-dimensional, that is, $H_y = 0$; $\partial H_x/\partial y = \partial H_z/\partial y = 0$; the current density $\mathbf{j}$ then has only a $y$-component.

The condition for static equilibrium can only be satisfied by magnetic fields for which $\mathbf{j} \exp z/h$ is constant on a line of force, where $h$ is the scale height. Given such a field, the pressure is determined apart from an arbitrary constant. A particularly useful family of solutions is provided by a set of lines of force, such that any magnetic field having these lines of force satisfies the above condition.

These lines of force are the lines of constant $F$, where

$$F = \exp(-z/h) - 2\exp(-z/2h)\cos(x/2h) + 1 \qquad (1)$$

and are shown in the diagram. For $F < 1$, they are closed curves, and the advantage of this family of solutions is that the magnetic field can be taken to vanish outside one of these closed lines of force, so avoiding any difficulty with boundary conditions. The horizontal width of the closed curves does not exceed $2\pi h$.

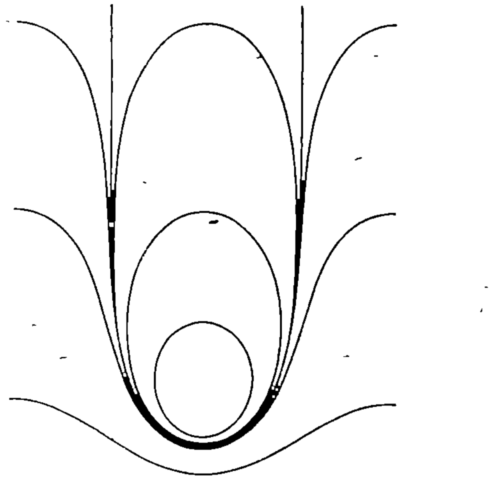
The effect of the magnetic field on the gas pressure $p$ can be expressed in terms of the magnetic pressure $p_H$ given by:

$$p_H = H^2/8\pi. \qquad (2)$$

Both $p \exp z/h$ and $p_H \exp z/h$ are constant on a line of force for this family of solutions, and the variation of pressure is given by:

$$\frac{d}{dF}[\{\exp(z/h)\}(p + p_H)] = (-\exp z/h)\, p_H/F, \qquad (3)$$

which shows that $(\exp z/h)(p + p_H)$ increases towards the inside of the closed curves.



The two-dimensional form of these solutions makes them appropriate for those prominences which appear as filaments on the disk of the sun, and the effect expressed by (3) may explain the high pressure of prominences relative to the surrounding gas; but, because prominences are much cooler than the corona, the isothermal model must be seriously wrong in some respects. There seems to be much better justification for applying this model to the arches seen in the corona above prominences, as these may well be nearly isothermal. They are seen in white light at eclipses and are difficult to photograph; but a drawing reproduced in the "Handbuch der Astrophysik", 4, 200 (1929), shows arches which resemble the theoretical curves. The outer arches appear to be near the limiting width, $2\pi h$; the width of the outer arch is about a quarter of the solar radius, and the temperature required to make these fit is about $10^6$ K., which is the accepted value for the temperature in the corona.

## The Lorentz Transformation

ON the basis of rather less restrictive postulates concerning the behaviour of light than are customary in special relativity theory, Capildeo has recently[1] given the transformation equations

$$\alpha x' = x - Vt, \quad y' = y, \quad z' = z, \quad \alpha t' = t - Vx/c^2, \qquad (1)$$

connecting two frames of reference $S$ and $S'$ (with suitably oriented axes) in uniform relative motion, where, it is suggested, the value of $\alpha$ cannot be uniquely determined without additional evidence. If, however, we consider three frames of reference $S$, $S_1$, $S_2$, where the velocities of $S_1$, $S_2$ relative to $S$ are $V_1$, $V_2$ along $Ox$, $Oy$, respectively, then, with the obvious notation,

$$\alpha_1 x_1 = x - V_1 t, \quad y_1 = y, \quad z_1 = z, \quad \alpha_1 t_1 = t - V_1 x/c^2,$$

and

$$x_2 = x, \quad \alpha_2 y_2 = y - V_2 t, \quad z_2 = z, \quad \alpha_2 t_2 = t - V_2 y/c^2,$$

and it will be found after rotating the $x$-axes of $S_1$ and $S_2$ into the direction of their mutual relative velocity that the new co-ordinates in $S_1$ and $S_2$ are connected by equations of the form (1) for all $V_1$ and $V_2$ if, and only if,

$$\alpha_t = \sqrt{1 - V_t^2/c^2}.$$

It thus appears that the Lorentz transformation is the only one consistent with Capildeo's assumptions.

In fact, it is possible, using similar reasoning, to derive the Lorentz transformation on very much weaker assumptions which do not involve any assertions about the behaviour of light. Suppose we assume merely that any two frames of reference $S$ and $S'$ in uniform relative motion are connected (with the usual choice of axes) by a transformation of the form

$$\alpha x' = x - Vt, \quad y' = y, \quad z' = z, \quad \gamma t' = t - \mu x, \quad (2)$$

where $V$ is the velocity of $S'$ relative to $S$ according to an observer fixed in $S$. It then follows, by considering frames of reference moving relative to $S$ in two perpendicular directions as before, that:

$$\text{(i)} \quad \alpha = \sqrt{1 - V^2/c^2}, \qquad \mu = V/c^2,$$

where $c$ is an absolute velocity for an observer fixed in $S$, independent of the magnitude and direction of the relative velocity of $S'$;

$$\text{(ii)} \quad \alpha/\gamma = c/c' = V/V',$$

where $c'$ is the absolute velocity in $S'$ and $V'$ is the magnitude of the relative velocity according to an observer fixed in $S'$; and

(iii) a velocity $c$ in any direction relative to $S$ is transformed into a velocity $c'$ relative to $S'$.

Thus (2) represents a Lorentz transformation combined with the introduction of an arbitrary factor in the scale of time in $S'$; and, in order to obtain the Lorentz transformation exactly, it is necessary to postulate further only that the time-scales in $S$ and $S'$ are such that both assign the same magnitude either to the absolute velocity or to their mutual relative velocity.

## Exchange of Carbon-13 Dioxide between Calcite Crystals and Gaseous Carbon Dioxide

FROM previous results[1], it is apparent that considerable exchange occurred between gaseous carbon dioxide and calcite crystals at high temperatures. This effect has been studied further.

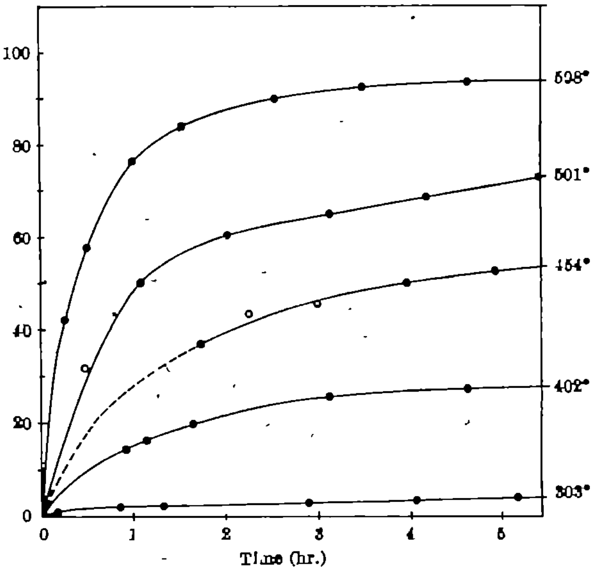
Calcite samples (100 mgm.) of known area were heated in a silica vessel containing enriched carbon dioxide (about 15 per cent $^{13}CO_2$) in the temperature range 300–800° C. The carbon dioxide pressure was at all times maintained well above the corresponding dissociation pressure. The reaction vessel was directly attached to a Consolidated–Nier type mass-spectrometer and the degree of exchange in the crystal was followed by measuring the decrease of carbon-13 in the gas. By a special mixing technique, small representative samples were drawn off and recycled after analysis. Constant temperatures were maintained with an electronic relay and the temperatures were automatically recorded.

It has been reported that, in the presence of water vapour, carbon dioxide exchanges with solid barium carbonate[2]. In the present investigation, with calcite, it was also found that water vapour enhanced the exchange appreciably. Even at room temperature, 3 per cent exchange occurred with the sample of largest surface area. Rigidly dry conditions were therefore maintained in all the experiments reported.

Results indicated that an initial rapid exchange, obviously due to surface and boundary effects, was followed by a slower process. This surface effect was confirmed by measuring exchange at 600° C. on samples prepared by sedimentation of finely ground Iceland spar and on a sample of precipitated calcite ('Witcarb *R*'). The specific surface areas (permeability method) were $5 \cdot 4 \times 10^3$, $3 \cdot 9 \times 10^4$, $10 \cdot 1 \times 10^4$ and $6 \cdot 9 \times 10^5$ cm.$^{-1}$, with a corresponding exchange after five hours of 3, 6, 8·5 and 93 per cent, respectively. Although these results are not quantitatively related, the trend of greater exchange with increasing area is definite. It is known that for larger particles permeability areas may be considerably lower than the reactive surface and, since isotopic exchange between gases and solids is a structure-sensitive phenomenon, discrepancies are to be expected.

Results obtained with 'Witcarb *R*' at temperatures from 300° to 600° C. are presented graphically. The degree of initial exchange increases considerably with temperature, indicating a greater penetration of the crystals. Exchange at 700° and 800° C. was, surprisingly, somewhat lower than at 600° C. (90 instead of 93 per cent). This may, however, be explained by assuming that annealing of the crystals occurs at these temperatures, with a consequent decrease in reactive surface.

For the 303° C. experiment, assuming complete exchange in the surface region and using the surface area determined by Brunauer, Emmett and Teller, it was calculated that a thickness of 2·7 A. was affected. This corresponds to a monolayer and is in agreement with Winter's findings[3] on the exchange between oxygen-18 and aluminium oxide. At higher temperatures, however, the affected thickness is



much larger and the calculation fails, since there is no distinction between an initial surface exchange and exchange within the crystal.

For the investigation of the slower process which succeeded the surface exchange, the sample of specific surface area $5 \cdot 4 \times 10^3$ cm.$^{-1}$ was chosen. This sample gave a readily measurable degree of exchange without being too deeply penetrated, even at high temperatures. The diffusion process could thus be treated as a one-dimensional problem, and a straight line should result when the decrease in carbon-13 dioxide concentration is plotted against the square root of time. Two distinct straight lines were, in fact, obtained, corresponding to the initial surface exchange and to the slower diffusion within the lattice. Diffusion coefficients were calculated from the related curves for 600°, 700° and 800° C. and resulted in values of 2·37, 10·8 and $41 \cdot 7 \times 10^{-17}$ cm.$^2$/sec. This corresponds to a value of $D_0$ of $1 \cdot 81 \times 10^{-10}$ cm.$^2$/sec. and an activation energy of 27,700 cal./mole, which is 0·67 of the heat of decomposition of calcite.

It appears that exchange may occur by a mechanism in which a carbonate ion momentarily breaks up into a carbon dioxide molecule, leaving an oxygen ion in the site. This carbon dioxide molecule then passes to a neighbouring site similarly vacated and combines with the oxygen ion to reform a carbonate ion. This mechanism is more likely than a process involving the movement of the larger carbonate ions as a whole, since the charge distribution in the lattice remains undisturbed.

## Graphitic Acid from Aromatic Compounds by Peroxide Treatment

Hydrogen peroxide in hot dilute aqueous solution, buffered by dilute acid such as sulphuric or boric acid, in the presence of either cupric or ferric ions, is capable of oxidizing a wide variety of aromatic (and aliphatic) compounds to carbon dioxide and water. Benzene, diphenyl, naphthalene, benzoic acid, toluic acids, phthalic acids, phenols, as well as a considerable number of amino-, nitro-, chloro- and bromo-derivatives of benzene and naphthalene, are all converted to carbon dioxide, water, ammonium salts, nitrate and halide ion in yields approaching 100 per cent under optimum conditions.

During an investigation of the kinetics and stoichiometry of these reactions, it has been observed repeatedly that as the original mixture disappears a transient brown coloration develops in the solution. The typical behaviour is shown when 0·1 gm. of phenol in 20 c.c. of strong solution of boric acid is treated with 5 c.c. of 100-vol. peroxide and 0·1 c.c. of 0·1 *M* copper sulphate solution. When this solution is heated to about 90° C., it rapidly darkens to a dense brown colour, oxygen and carbon dioxide being evolved vigorously. On continued heating, with the addition of further peroxide if necessary, the brown colour fades completely. Considerable variations in the concentrations have little effect on the general changes, although the presence of the trace metal is essential[1].

The brown material is colloidal in nature as indicated by the ultra-microscope and the Tyndall cone; but its coagulation is very difficult indeed. Larger quantities of the material have been prepared by allowing hydrogen peroxide to react with benzene refluxing in a Soxhlet extraction apparatus. In this way the brown material can be prepared dispersed in an organic phase with little inorganic contamination.

Solid samples prepared by evaporation of the benzene had the following analysis: C, 55·91; H, 4·0; O, 40·1 per cent; but no melting point observable. The chemical and physical properties of the material indicate that it is of the same general type as 'graphitic acid'. It is insoluble in inorganic acids and reagents, but is peptized in very dilute ammonium or alkali hydroxide. It is insoluble in the majority of organic solvents, but from either glacial acetic acid or concentrated sulphuric acid (in both of which it appears to disperse) it may be recovered unchanged by evaporation of the acid from a hot slide. There are no detectable functional groups, the only reagents which show the slightest action being powerful oxidizing agents such as acid-permanganate or hydrogen peroxide (130-vol.), in which it dissolves with evolution of carbon dioxide.

Specimens of 'graphitic acid' have been prepared from various specimens of graphite with nitric–sulphuric acid mixtures to which potassium chlorate is added in small quantities over a period of time. The samples are purified by centrifugation and dialysis. The physical and chemical properties of the materials from peroxide appear identical with the standard specimens. Ultra-violet spectroscopy fails to discriminate between the two series. It is hoped to carry out X-ray and thermal analysis shortly.

It is rather difficult to visualize the transformation of benzene into a graphitic acid; but it is presumably via the addition or polymerization of aromatic radicals into the necessary two-dimensional structure between which oxygen atoms are trapped.

The formation of 'graphitic acid' analogues by the peroxide oxidation of aromatic compounds may have connexions with the synthesis of humic acid, peat and coal under natural conditions.

The formation of the brown material from aromatic compounds is not limited to peroxide oxidations. Analogous reactions can be brought about by prolonged anodic oxidation, electrodeless discharge, X-rays or photo-radiation and by various chemical reagents such as persulphate[1]. The parallelism with the hydrogen peroxide process is remarkable, suggesting that the same active entity, OH or $HO_2$, might be operative in all such cases.

# FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

### Tuesday, April 7

Society of Chemical Industry, Plastics and Polymer Group (at the Royal Society of Tropical Medicine and Hygiene, Manson House, 26 Portland Place, London, W.1), at 6.30 p.m.—Dr. M. Gordon and Mr. J. S Taylor: "Recent Advances in the Ionic Reactions of Rubber". (Members of the Institution of the Rubber Industry are invited.)

### Wednesday, April 8

Institute of Petroleum (at Manson House, 26 Portland Place, London, W.1), at 5 30 p.m.—Dr. W. C. Dickerman, jun.: "The Present Status of the Art of Cracking".*

Royal Statistical Society, Study Section (at the E.L.M.A. Lighting Service Bureau, 2 Savoy Hill, London W.C.2), at 6 p.m.—Mr. E. Shankleman Summary of the results of a Survey on the Forecasting of Economic Indices by Economists.

British Institution of Radio Engineers (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 6.30 p.m.—Lieut.-Colonel J. P. A. Martindale: "Lens Aerials for Centimetric Wave-lengths".

### Wednesday, April 8—Saturday, April 11

Mathematical Association (at the University, Sheffield).—Annual General Meeting.

### Thursday, April 9

Bone and Tooth Society (at the Institute of Orthopaedics, 234 Great Portland Street, London, W.1), at 5 p.m.—Symposium on "Vitamin C and Bone".

Society of Dyers and Colourists (at the Royal Institution, 21 Albemarle Street, London, W 1), at 7.30 p.m.—Mr. J. R. Blockey and Mr. D. H. Tuck: "The Coloration of Leather" (Tenth Mercer Lecture).*

### Thursday, April 9—Monday, April 13

British Psychological Society (at Nottingham).—Annual General Meeting.

### Friday, April 10

Royal Astronomical Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m—Scientific Papers.

Institution of Mechanical Engineers (joint meeting with the Education Group, at Storey's Gate, St. James's Park, London, S.W.1), at 5.30 p.m.—Dr. W. Abbott: "The Athlone Fellowship Scheme for the Practical Training in Industry of Canadian Engineering Graduates in Great Britain".

### Saturday, April 11

Biochemical Society (joint meeting with the Société Belge de Biochimie, in the Faculty of Medicine, The University, 115 Boulevard de Waterloo, Brussels), at 9 a.m.—Scientific Papers.

---

# APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Assistant Advisory Officer in Grassland Husbandry, and an Assistant Lecturer in Agricultural Engineering—The Secretary, North of Scotland College of Agriculture, 41½ Union Street, Aberdeen (April 11).

Biochemist (honours science graduate) primarily for research duties in the Geriatric Department of the Sunderland Hospital group—The Senior Administrative Officer, Newcastle Regional Hospital Board, Blythswood South, Osborne Road, Newcastle-upon-Tyne 8 (April 11).

Senior Lecturer or Lecturer to teach Electrical Engineering to ordinary national certificate and higher national certificate standards—The Principal, School of Electronics, Malvern, Worcs (April 11).

Physicist (Senior Experimental Officer grade) to organize and supervise operations involving processing of radioactive materials, and responsible for accounting and movement control of active materials used by research and development group (Ref. A.68/53A), and Physicists (Assistant Experimental Officer grade) for radiological work, and for work involving various types of radiation measurement (Ref. A.69/53A), at the Ministry of Supply Establishment, Aldermaston—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting the appropriate Ref No. (April 18).

Chair of Geography in the University College of Khartoum, Sudan—The Secretary, Inter-University Council for Higher Education in the Colonies, 1 Gordon Square, London, W.C.1 (April 25).

Lecturer in Engineering (with qualifications in civil engineering, and special interests in structures or hydraulics)—The Registrar, The University, Manchester 13 (April 25).

Principal Research Officer or Senior Research Officer (with university honours degree in science or agriculture or equivalent qualification, proved ability in leadership, and considerable experience in tropical agriculture or field experience in geology, pedology or ecology) to lead a scientific unit that will include a geologist, geomorphologist, pedologist, ecologist, and systematic botanist, to carry out surveys in Papua and New Guinea (headquarters at Canberra)—The Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2, quoting No. 570/23 (April 25).

Scientific Technical Officer, Grade II (with a good general training in chemistry, preferably up to degree standard, experience in fuel technology and fuel analysis an advantage), at the Coal Survey Laboratory at Nottingham—The National Coal Board, Establishments (Personnel), Hobart House, Grosvenor Place, London. S.W.1, quoting TT/612 (April 25)

Assistant Lecturer or Lecturer in Mechanical Engineering—The Registrar, The University, Leeds 2 (April 27).

Lecturer in Zoology—The Registrar, Queen Mary College, Mile End Road, London, E.1 (April 27).

Assistant Lecturer in Chemistry (with a special interest in physical or inorganic chemistry), an Assistant Lecturer in Geology, Assistant Lecturers in Mathematics (one with special qualifications in applied mathematics), an Assistant Lecturer in Physics, and an Assistant Lecturer in Psychology—The Secretary, Birkbeck College, Malet Street, London, W.C.1 (April 30).

Assistant Lecturer or Lecturer in Pure Mathematics—The Registrar, University College of North Staffordshire, Keele, Staffs (April 30).

Lecturer or Assistant Lecturer in Anatomy—The Secretary of the Medical School, St. Thomas's Hospital, London, S.E.1 (May 1).

Director of the National Botanic Gardens of South Africa, Newlands, Cape Province—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (Newlands, May 15).

Royal Dutch Shell Studentship in Geophysics—The Registrar, Imperial College of Science and Technology, South Kensington, London, S.W.7 (May 30).

Melville Trust Fellowships in Cancer Research, tenable in Edinburgh—Messrs. Tods, Murray and Jamieson, W.S., 66 Queen Street, Edinburgh 2 (May 31).

Assistant in the Department of Engineering—The Secretary, The University, Edinburgh (June 1).

Assistant (with degree or equivalent in metallurgy, chemistry, physics or engineering) in the Information Department—The Secretary, British Non-Ferrous Metals Research Association, 81–91 Euston Street, London, N.W.1.

Assistant Chief Engineer (Design) to take charge of teams of engineers and draughtsmen engaged on design and detailing of special mechanical and chemical plant—The Ministry of Supply, Division of Atomic Energy (Production), Risley, Warrington, Lancs, quoting 442.

Graduates in Medicine or Veterinary Medicine for post-graduate training in bacteriology and immunology—The Defence Research Member, Canadian Joint Staff London, Moncorvo House, 66 Ennismore Gardens, London, S.W.7, or The Director of Research Personnel, Defence Research Board, Department of National Defence, 'A' Building, Ottawa, Ontario, Canada.

Livestock Officer (with degree in agriculture or related subject with experience of animal husbandry) in the Veterinary Department, Nyasaland—The Director of Recruitment, Colonial Office, Great Smith Street, London, S.W.1, quoting CDE.67/4/03.

Metallurgist at the Royal Aircraft Establishment, Farnborough, to work in team engaged on titanium alloy development—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S W.1, quoting F.108/53A.

Microwave and Electronics Engineer or Physicist (with six to ten years experience) to carry out research and development on guided missiles, a Servo-Mechanisms Engineer to carry out research and development on guided missiles, an Electrical Engineer or Engineering Physicist (with experience in electronic computation) to carry out development work on aircraft fire control computers, an Electrical Engineer or Engineering Physicist to direct electronic designs and electronic systems production engineering for guided missile development, an Electronic Instrumentation Engineer to carry out instrumentation work on guided missiles, and Mechanical Engineers (with six to ten years experience) to carry out design and development on armament systems—The Defence Research Member, Canadian Joint Staff London, Moncorvo House, 66 Ennismore Gardens, London, S.W.7, or P.O. Box 1427, Quebec City, Quebec, Canada.

Physical Chemist for work on the oxidation of cellulosic materials—The Secretary, British Rayon Research Association, Barton Dock Road, Urmston, Manchester.

Physical Metallurgist (at Sheffield) to carry out research on the ageing of mild steel—The Personnel Officer British Iron and Steel Research Association, 11 Park Lane, London, W.1, quoting 'Ageing of Steel'.

Research Officer (chemist or chemical engineer, with a first- or second-class honours degree or an associateship of the R I C.)—The Director, British Paper and Board Industry Research Association, Welcomes Road, Kenley, Surrey.

Soil Physicist (with good honours degree in physics or chemistry, including physical chemistry, with at least two years postgraduate experience or training in soils physics)—The Director of Recruitment, Colonial Office, Great Smith Street, London, S.W.1, quoting 27106/52.

Specialist Technical Editor (with honours degree in mathematics, physics or engineering and ability to deal with mathematics up to at least degree standard) in the Ministry of Supply, Chessington, to prepare instructional text-books on guided weapons, involving collation of information and editing contributions—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S W.1, quoting A.70/53A.

# PROBLEMS OF EMPLOYMENT IN AN AGEING POPULATION

THE thoughtful address on the employment of the older worker which Sir Frederic Bartlett delivered in October 1951 in the Centenary Lectures given under the auspices of the Ministry of Labour attracted comparatively little attention at the time. Its significance is emphasized by the report of the Royal Commission on Population, and is apparent from current discussions of the trend of population in Britain in the next few decades provoked by that report. It is now widely recognized that, in a society with an ageing population, it is desirable and even essential that the elderly should remain longer at work. As Sir Frederic Bartlett suggested, the increasing needs of humanity can only be met if all fit people, from youth to age, play their parts; and only if those parts, moreover, are planned in accordance with the natural flowering and growth throughout life of human abilities.

It is against this background that the importance and value of the work of the Nuffield Research Unit on the Problems of Ageing, established by the Foundation in the Psychological Laboratory of the University of Cambridge under Sir Frederic Bartlett, and Mr. F. Le Gros Clark's research on the continued employment of the elderly, are best appreciated. Some attention, it is true, was given to it at the Conference on Human Relations in Industry arranged by the Ministry of Labour and National Service in March 1952*, and the Labour Party's pamphlet "The Welfare State" recognizes that it is becoming imperative for old people to stay in employment, even if not in their recognized jobs or in a full-time capacity. The question of a later retiring age is frankly faced in this pamphlet, and, whereas it has generally become difficult even for those past forty to obtain fresh posts, the Post Office has become the first government department to practise the policy—which successive Governments have advocated since the War—of deliberately encouraging the elderly to apply for work. The maximum age of recruitment for postmen, van-drivers and telephonists has been raised from forty-five to sixty, and the Union of Post Office Workers has shown humanity and a proper understanding of national needs in agreeing to co-operate in working the new scheme.

While this scheme sets an example for industry generally to follow, the Chancellor of the Exchequer has tackled boldly the problem of retirement in the Civil Service, and ruled that Civil servants who are still capable of doing their job, and who wish to continue, need not retire at sixty. This, of course, means deferred promotion, and probably deferred increases in pay for others; but it is understandable that Mr. Butler has rejected a request from the Civil Service unions that those older than sixty who remain at work should be transferred to grades that do not block promotion. The Treasury will not wish to be forced to transfer a man from some post where he is particularly useful, and it should be recognized, as the Minister of Labour points out in a pamphlet entitled "Employment of Older Men and Women", that while blocked retirement presents real difficulties for younger people, the increased expectation of life, as well as the raising of the retirement age, both tend to ensure that the ultimate tenure of senior posts by those whose path is temporarily blocked will not be shorter than under schemes of compulsory retirement.

---

* Ministry of Labour and National Service. Report of the Human Relations in Industry Conference, held at the Institution of Civil Engineers, London, March 18–20, 1952. Pp. vi+128. (London: H.M.S.O., 1952.) 3s. 6d. net.

That does not, of course, entirely dispose of the difficulty; but it could also be mitigated by measures for increasing salaries on merit, without necessarily waiting for promotion. Furthermore, there are men who would be happy enough to stay at work in a position of less responsibility, and, even in the Civil Service, it should not be impossible to deal with such cases without making hard-and-fast rules. Particularly where the most senior positions are concerned, this might indeed come to be the most usual situation for, as has been pointed out by H. R. Hill in a recent American book, "Some Observations on Executive Retirement", in a society where not only the population is ageing but also business and administration are becoming more complex, the strain of executive responsibility more onerous, and adaptability more important, age is a growing handicap less and less compensated by length of experience.

In such circumstances, it should be the normal rather than the exceptional practice for those who remain at work on passing what is at present regarded as the customary age of retirement, to step down or aside into other positions rather than continue in their existing posts. Such a practice very clearly involves considerable administrative problems, but it is manifestly one in the national interest and is fully supported by the trend of the research work to which Sir Frederic Bartlett referred. Opposition to the raising of the retirement age, such as that voiced by Mr. J. Haworth, treasurer of the National Federation of Professional Workers, appears to be out of keeping with both the trend of the change in age-structure of the population and the changes in national and social interests which must result.

Sir Frederic Bartlett's observations in the address noted were based upon the general results of the work of the Unit for Research into Problems of Ageing. Available evidence, he pointed out, implies that the great majority of a contemporary healthy population could continue efficiently and economically to meet the main demands of industry, at least up to what is still taken to be the normal span of life. There is no doubt, however, that for all manner of skills, from simple combined bodily movements to complex high-level mental skills requiring executive and administrative decisions based upon evidence collected from many sources, the overall preferred speed of work diminishes as age increases. If the speed of work is set by the conditions of work themselves, the cost of maintaining this speed, unless the methods of work are changed, may become much more punishing, especially over fifty.

This difficulty of speed, and especially impos speed, cannot, Sir Frederic pointed out, be remov entirely by regard for what are called 'hum relations', or by systems of management alone. Bo can help, but the basic requirement is to pl operations, and especially the design of display ar control, with the view of the most widely distribut natural range of abilities in whatever workin populations are concerned, and in doing this to ma age-group an important consideration. To do this and Sir Frederic is certain it will have to be done would make the problems of re-orientation, re-learnin and perhaps switch of occupation in the mo advanced age-groups, acute and critical; but he se no insuperable obstacles to such an extension planned occupational design.

The Nuffield Unit is already providing a fir factual basis for policy, given the goodwill and t co-operation required to make any such poli effective. Moreover, as Mr. J. Marsh, director of t Industrial Welfare Society, noted, in dealing wi the subject at the Human Relations Conference March last year, industry needs to remember co stantly the great help which the medical professio could give. It is already clear that men can car on with manual skills for many years, though it less certain that they can carry on with mental ski for so long. The main thing is to alter our attitu towards occupation and old age. Mr. Marsh su gested that, particularly in the administrative a clerical grades, we might need to explore the po sibilities of interchangeable pension schemes so as facilitate the movement of men between forty a fifty-five to jobs which gave them fuller scope, a that we also need to explore more fully the po sibilities of what might be called 'demotion witho disgrace'.

Discussions on the subject at this Conferen pointed to the desirability of terminating ol fashioned artificial age-restrictions for certain emplo ments, many of which are out of date to-day a only create ill-feeling and frustration. Neverthele the undesirability of persons remaining in positio of responsibility after they have passed the sta when they are fully effective was recognized; thou to implement a policy of 'demotion without disgra a change of attitude is required, not only on the pa of management but also of workers, if they are accept that it may be necessary in old age to tak job of lower status and salary. So far as man workers are concerned, there was agreement that t aim must be to secure that older persons willing a able to work should not be denied this opportuni on grounds of age alone. The test should be abili to do the job and not date of birth; but no co pulsion to go on working should be applied to work if they wish to retire.

It was agreed at this Conference that there is widespread desire on the part of many workers continue work past their present retiring age, a that employers should aim at transferring workers more suitable work at any time when their a becomes a handicap. Skilled workers can genera be expected to carry on into old age in their norm work, and the transfer process would affect only a mall proportion of all manual workers. The posibility of making the change in middle life to jobs which could be carried on in old age merits consideration, and wherever possible the change should be made within the organization.

It is thus high time that more attention was given to the whole question of retirement and its implications in our changing population structure. It is not sufficient for industry generally to follow the example which has already been set by the Post Office and by Mr. Butler in the Civil Service; nor can we be content to continue or to extend the work already being carried out by the Nuffield Research Unit. What is wrong with our present arrangements is, as Mr. W. A. B. Hopkins, of the National Institute of Economic and Social Research, pointed out in a recent article on "The Economics of an Ageing Population" (*Lloyds Bank Review*, January 1953), not that the pension is conditional on retirement, but that retirement with a pension is available, and often compulsory, to people very many of whom would be quite capable of staying at work for some time longer. As already seen, in recent years a good deal of evidence has accumulated to show that it is rather the exception than the rule for a man to be genuinely past work at sixty-five.

Even if there were no adverse demographic tendency to combat, it would be sensible to try to alter the arrangements which cause waste of productive economic resources; but the first and most essential step, Mr. Hopkins argues, is to eliminate from the national insurance system the commitment to provide a retirement pension at a definite age laid down years, or even decades, in advance. Mr. Hopkins recognizes that the presentation of the scheme to the public in the past has been such as to cause false impressions and to create expectations which may well lead to resentment when a government is compelled, as he believes is inevitable, to raise the pension age. Nevertheless, he believes it is necessary that the principle should be publicly established that the age at which retirement pension may be claimed is variable, and will probably be raised as time goes on. As he admits, a government which made such an announcement would obtain no immediate credit, and would probably incur some immediate odium. It would, however, earn the gratitude of its successors by establishing the conditions in which pension arrangements could eventually be adjusted to changes in the demographic and economic circumstances of the country. No political party has, however, yet given any signs of the courage demanded in taking such a step; and it is therefore the more important that private as well as public industry should follow the example already set by government departments and at least experiment in this direction.

Such experiments in themselves encourage the development of a climate of opinion favourable to the pronouncement for which Mr. Hopkins calls. It should be recognized, however, that for a policy of later retirement to act fairly and effectively, uncertainty must be removed so far as possible. Save where it depends on experimental work such as the Nuffield Research Unit is conducting, the experimental period should be short. This point was well put by the Master of Sydney Sussex College, Cambridge, Mr. Thomas Knox-Shaw, in discussing the question of university retirement in the *Universities Quarterly* of August 1952. Compulsory retirement in a university at sixty-five, he thought, is often wasteful as well as painful; but while clearly time is required to explore the different possibilities and alternatives to which he points, it is essential to terminate as early as possible the uncertainties which such discussions are bound to raise in the minds of those immediately affected. The question of retiring age is undoubtedly one which requires urgent and full discussion, not only by the universities but also by professional bodies generally as well as by industry. Such discussion, even more than unilateral action, can promote the formation of the public understanding which is so essential. That it should be regarded as a matter of urgency is dictated both by individual and the national interest.

# CHEMISTRY'S DEBT TO RADIOACTIVITY

## Radioactivity applied to Chemistry

Arthur C. Wahl (editor), Norman A. Bonner (associate editor). Pp. xv+604. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1951.) 60*s*. net.

Although it is not yet sixty years since Henri Becquerel discovered the uranium rays, the rapid growth of the science of radioactivity has completely changed physics, profoundly influenced chemistry, and provided biology and medicine with new methods. It has become more and more difficult to keep pace with the radioactive studies even in one of these fields, and many chemists will be very glad that, so far as their science is concerned, an extremely useful survey of the literature up to 1950 is now available.

Twelve men of science have collaborated in producing a stately volume of six hundred pages, but the presentation of the subject could not be more consistent if it had been the work of a single author —a sign of the great care exercised by the editors in co-ordinating the work of the contributors. As the title of the book indicates, it was not their aim to deal with all aspects of radioactivity which might well be of interest to the chemists, but only with its application to the solution of chemical problems. 'Radiation chemistry' is only very briefly dealt with, and some branches of 'radiochemistry' are not mentioned. No reference is made to radiochemical techniques, or to the preparation of tagged compounds; but within the self-imposed limits the editors have aimed at completeness, and it seems that they have very well achieved their goal. Even recondite references of small importance have been found to be included. In Part 1 of the book—some three hundred pages—the usefulness of radioactive indicators is shown by a description of their application to a great variety of chemical problems; it will be found very useful by all interested in the subjects mentioned but not acquainted with the radioactive method of their investigation. About two hundred pages of Part 2 give a summary of the relevant literature, and the rest contains the bibliography and the index.

In the preface the principal editor states that the contributors to this book became interested in the application of radioactivity to chemistry only during the Second World War, that they were then unfamiliar with most of the earlier work, and that the book is the outcome of their effort to correct this situation. It is therefore not astonishing that, in spite of the thoroughness of their search through the literature, they did not always gain the historical perspective which would come naturally to authors who were contemporaries of the earlier radiochemical investigations. Sometimes one would have preferred a different grouping. For example, in the days when no bismuth hydride was known, its discovery by the use of a radioactive isotope was interesting as a contribution by a new method to preparative inorganic chemistry, but scarcely as an example of "evaporation from solution", the heading under which it is here classified. A strange historical slip could not have happened to a veteran in the field; it is stated that neon, krypton, xenon, europium, lutetium, hafnium and rhenium were found in the period 1898–1925 by the method of X-ray spectroscopy; but Moseley's fundamental work on which X-ray spectroscopy is based was done only in 1913, and even after that date its application to the discovery of inert gases can scarcely be imagined. Hafnium and rhenium are the only examples where X-ray spectroscopy was used; for the discovery of the other five elements, the old-fashioned optical spectroscopy was decisive.
